Sophocles is often praised for skilful construction. But the secret of his skill depends in large measure on the profound way in which the central situation in each of his fables has been conceived and felt. Concentration is the distinguishing note of tragedy, and it is by greater concentration that Sophocles is distinguished from other tragic poets. In the *Septem contra Thebas* or the *Prometheus* of Aeschylus there is still somewhat of epic enlargement and breadth; in the *Hecuba* and other dramas of Euripides separate scenes have an idyllic beauty and tenderness which affect us more than the progress of the action as a whole, a defect which the poet sometimes tries to compensate by some novel *dénouement* or catastrophe. But in following a Sophoclean tragedy we are carried steadily and swiftly onward, looking neither to the right nor to the left; the more elaborately any scene or single speech is wrought the more does it contribute to enhance the main emotion, and if there is a deliberate pause it is felt either as a welcome breathing space or as the calm of brooding expectancy.

The result of this method is the union, in the highest degree, of simplicity with complexity, of largeness of design with absolute finish, of grandeur with harmony. Superfluities are thrown off without an effort through the burning of the fire within. Crude elements are fused and made transparent. What look like ornaments are found to be inseparable from the organic whole. Each of the plays is admirable in structure, not because it is cleverly put together, but because it is so completely alive.

The seven extant tragedies probably owe their preservation to some selection made for educational purposes in Alexandrian times. A yet smaller "syllogê" of three plays (*Ajax*, *Electra*, *Oedipus Tyrannus*) continued current amongst Byzantine students and many more copies of these exist than is the case with the other four. Of these four the *Antigone* seems to have been the most popular, while an inner circle of readers were specially attracted by the *Oedipus Coloneus*.

No example of the poet's earliest manner has come down to us. The *Antigone* certainly belongs to the Periclean epoch, and while Creon's large professions (lines 175–190) have been supposed to reflect the policy of the Athenian statesman, the heroine's grand appeal to the unwritten laws may have been suggested by words which an Attic orator afterwards quoted as having been spoken by Pericles himself: "They say that Pericles once exhorted you that in the case of persons guilty of impiety you should observe not only the written laws, but also those unwritten, which are followed by the Eumolpidae in their instructions—laws which no man ever yet had power to abrogate, or dared to contradict, nor do the Eumolpidae themselves know who enacted them, for they believe that whoso violates them must pay the penalty not only to man, but to the gods" ([Lysias] *contra Andocidem*, § x. p. 104).

Modern readers have thought it strange that Creon when convinced goes to bury Polynices before attempting to release Antigone. It is obvious how this was necessary to the catastrophe, but it is also true to character, for Creon is not moved by compunction for the maiden nor by anxiety on Haemon's account, but by the fear of retribution coming on himself and the state, because of the sacred law of sepulture which he has defied. Antigone is the martyr of natural affection and of the religion of the family. But, as Kaibel pointed out, she is also the high-born Cadmean maiden, whose defiance of the oppressor is accentuated by the pride of race. She despises Creon as an upstart, who has done outrage not only to eternal ordinance, but to the rights of the royal house.

The *Ajax*, that tragedy of wounded honour, still bears some traces of Aeschylean influence, and may be even earlier than the *Antigone*. But it strikes the peculiarly Sophoclean note, that the great and noble spirit, although through its own or others' errors it may be overclouded for a time and rejected by contemporaries amongst mankind, is notwithstanding accepted by the gods and shall be held in lasting veneration. The construction of the *Ajax* has been adversely criticized, but without sufficient reason. If it has not the concentration of the *Antigone*, or of the *Oedipus Tyrannus*, it has a continuous movement which culminates in the hero's suicide, and develops a fine depth of sympathetic emotion in the sequel.

In the *King Oedipus* the poet attains to the supreme height of dramatic concentration and tragic intensity. The drama seems to have been produced soon after the outbreak of the Peloponnesian War, but certainly not in the year of the plague—else Sophocles, like his predecessor Phrynichus, might be said to have reminded his countrymen too poignantly of their home troubles. "The unwritten laws" are now a theme for the chorus. The worship of the Delphic Apollo is associated with a profound sense of the value and sacredness of domestic purity, and in the command to drive out pollution there is possibly an implied reference to the expulsion of the Alcmaeonidae.

The *Electra*, a less powerful drama, is shown by the metrical indications to be somewhat later than the *Oedipus Rex*. The harshness of the *vendetta* is not relieved as in Aeschylus by long-drawn invocations of the dead, nor, as in Euripides, is it made a subject of casuistry. Electra's heroic impulse, the offspring of filial love, through long endurance hardened into a "fixed idea," is irrepressible, and Orestes, supported by Pylades, goes directly to his aim in obedience to Apollo. But nothing can exceed the tenderness of the recognition scene—lines 1098–1321, and the description of the falsely reported chariot race (681–763) is full of spirit.

In the *Trachinian Maidens* there is a transition towards that milder pathos which Sophocles is said to have finally approved (ἠθικώτατον καὶ ἄριστον). The fate of Deianira is tragic indeed. But in her treatment of her rival, Iole, there are modern touches reminding one of Shakespeare. The play may have been produced at a time not far removed from the peace of Nicias; and if this were so Deianira's prayer that her descendants may never undergo captivity—lines 303-305—might remind Athenian matrons of the captive Heracleids from Pylos, descendants through Hyllus of Deianira herself. The "modern" note is even more conspicuous in the *Philoctetes*, where the inward conflict in the mind of Neoptolemus, between ambition and friendship, is delineated with equal subtlety and force, and the contrast of the ingenuous youth with the aged solitary, in whom just resentment has become a dominant idea, shows great depth of psychological insight. The tragic catastrophe of the *Oedipus Tyrannus* and the *Trachiniae* is absent here. The contending interests are reconciled by the intervention of the deified Heracles. But even more clearly than in the *Ajax* the heroic sufferer, rejected by men, is accepted by the gods and destined to triumph in the end. The *Philoctetes* is known to have been produced in the year 408 B.C., when Sophocles was 87 years old. The *Oedipus Coloneus* is said to have been brought out after the death of Sophocles by his grandson in the archonship of Micon, 402 B.C.

The question naturally arises, why a work of such surpassing merit should not have appeared in the lifetime of the poet. The answer is conjectural, but acquires some probability when several facts are taken into one view. It is surely remarkable that in a drama which obviously appeals to Athenian patriotism, local sanctities should obtain prominence to the exclusion of the corresponding national shrines on the Acropolis. It has been thought that the aged poet felt a peculiar satisfaction in celebrating the beauty and sacredness of his native district. This may well have been so, but could hardly supply a sufficient motive for a work destined to be presented to the assembled Athenians in the Dionysiac theatre. But there was a crisis in Athenian politics when "Colonus of the Knights" acquired a national significance. Those who organized the constitution of the Four Hundred made the precinct of Poseidon at Colonus the place of meeting, and probably sacrificed at the very altar which is consecrated by Theseus in this play. There must have been some reason for this. May it not have been that the occupants of the whole region, including the Academy, belonged mostly to the oligarchic faction? May not those who honoured Colonus by frequenting it—lines 62 and 63—have belonged to the order of knighthood? The name Colonus Hippius (or τῶν ἱππέων) would then have an appropriate meaning, and the equestrian statue of the eponymous hero (line 59) would be symbolical. In times of political agitation Colonus would then be regarded like St Germain, as the aristocratic quarter, while the Peiraeus was that of the extreme democracy, a sort of Faubourg St Antoine. It was there that the counter-movement reached its culmination. If so much be granted, is it not possible that this play, so deeply tinged with oligarchic influence, may have been thought too dangerous, and consequently withheld from production until after the amnesty, when the name of Sophocles was universally beloved, and this work of his old age could be prudently made public by his descendant? The knights in Aristophanes (424 B.C.) make their special appeal to Poseidon of the chariot race and to the Athene of victory. The Coloniates celebrate the sons of Theseus as worshippers of Athene Hippia, and of Poseidon.

Theseus in Euripides (*Supplices*) is the first citizen of a republic. In this drama he is the king whose word is law, and he is warned by Oedipus to avoid the madness of revolutionary change (lines 15361–538). The tragic story of Oedipus is resumed, but in a later and deeper strain of thoughtful emotion. Once more the noble spirit, rejected by man, is accepted by the gods. The eternal laws have been vindicated. Their decrees are irreversible, but the involuntary unconscious criminal is not finally condemned. He has no more hope in this world, but is in mysterious communion with unseen powers. The sufferer is now a holy person and an author of blessing. An approach is even made to the New Testament doctrine of the sacredness of sorrow.

Whatever may have been the nature of a Sophoclean tetralogy, the practice which at one time prevailed of describing the *Oedipus Rex*, *Oedipus Coloneus* and *Antigone* as "the Theban trilogy" was manifestly erroneous and misleading. The three plays belong to different periods in the life-work of the poet, and the *Antigone* is the earliest of the three.

The spectator of a Sophoclean tragedy was invited to witness the supreme crisis of an individual destiny, and was possessed at the outset with the circumstances of the decisive moment. Except in the *Trachiniae*, where the retrospective soliloquy of Deianira is intended to emphasize her lonely position, this exposition is effected through a brief dialogue, in which the protagonist may or may not take part. In the *Oedipus Tyrannus* the king's entrance and his colloquy with the aged priest introduce the audience at once to the action and to the chief person. In the *Ajax* and *Philoctetes* the entrance or discovery of the hero is made more impressive by being delayed. Immediately after the prologos the chorus enter, numbering fifteen, either chanting in procession as in the *Antigone* and *Oedipus Tyrannus*, or dispersedly as in the *Oedipus Coloneus* and *Philoctetes*, or, thirdly, as in the *Electra*, where, after entering silently during the monody of the heroine, and taking up their position in the orchestra, they address her one by one. With a remarkable exception, to be noted presently, the chorus, having once entered, remain to the end. They always stand in some carefully adjusted relation to the principal figure. The elders of Thebes, whose age and coldness throw into relief the fervour and the desolation of Antigone, are the very men to realize the calamity of Oedipus, and, while horror-stricken, to lament his fall. The rude Salaminian mariners are loyal to Ajax, but cannot enter into his grief. The Trachinian maidens would gladly support Deianira, who has won their hearts, but they are too young and inexperienced for the task. The noble Argive women can sympathize with the sorrows of Electra, but no sympathy can soothe her distress.

The parodos of the chorus is followed by the first scene or epeisodion, with which the action may be said to begin. For in the course of this the spectator's interest is strongly roused by some new circumstance involving an unforeseen complication—the awakening of Ajax (*Aj.*), the burial of Polynices (*Ant.*), the dream of Clytaemnestra (*El.*), the dark utterance of Teiresias (*Oed. Tyr.*), the arrival of Lichas with Iole (*Trach.*), the report of Ismene announcing Creon's coming (*Oed. Col.*), the sudden entreaty of Philoctetes crossed by the entrance of the pretended mariner (*Phil.*). The action from this point onwards is like a steadily flowing stream into which a swift and turbulent tributary has suddenly fallen, and the interest advances with rapid and continuous climax until the culmination is reached and the catastrophe is certain. The manner in which this is done, through the interweaving of dialogue and narration with the various lyrical portions, is very different in different dramas, one of the principal charms of Sophocles being his power of ingenious variation in the employment of his resources. Not less admirable is the strength with which he sustains the interest after the *peripeteia*,[1] whether, as in the *Antigone*, by heaping sorrow upon sorrow, or, as in the first *Oedipus*, by passing from horror to tenderness and unlocking the fountain of tears. The extreme point of boldness in arrangement is reached in the *Ajax*, where the chorus and Tecmessa, having been warned of the impending

[1] A tragic action has five stages, whence the five acts of the modern drama: the start, the rise, the height, the change, the close.

danger, depart severally in quest of the vanished hero, and thus leave not only the stage but the orchestra vacant for the soliloquy that precedes his suicide.

No such general description as has been here attempted can give even a remote impression of the march of Sophoclean tragedy—by what subtle yet firm and strongly marked gradations the plot is unfolded; how stroke after stroke contributes to the harmonious totality of feeling; what vivid interplay, on the stage, in the orchestra, and between both, builds up the majestic, ever-moving spectacle. Examine, for example, the opening scene or πρόλογος of the *Oedipus Tyrannus*. Its function is merely to propound the situation; yet it is in itself a miniature drama. First there is the silent spectacle of the eager throng of suppliants at the palace gate—young children, youths and aged priests. To them the king appears, with royal condescension and true public zeal. The priest expresses their heartfelt loyalty, describes the distress of Thebes, and, extolling Oedipus's past services, implores him to exercise his consummate wisdom for the relief of his people. The king's reply unveils yet further his incessant watchfulness and anxious care for his subjects. And he discloses a new object to their expectancy and hope. Creon, a royal person, had been sent to Delphi, and should ere then have returned with the response of Apollo. At this all hearts are trembling in suspense, when Creon is seen approaching. He is wreathed with Apollo's laurel; he looks cheerfully. What has Phoebus said? Another moment of suspense is interposed. Then the oracle is repeated—so thrilling to the spectator who understands the story, so full of doubt and hope and dread to all the persons of the drama: "It is for the blood of Laius—his murderers are harboured in the land of Thebes. The country must be purged." That is the culminating point of the little tragedy. While Oedipus asks for information, while in gaiety of heart he undertakes the search, while he bids the folk of Cadmus to be summoned thither, the spectators have just time to take in the full significance of what has passed, which every word that is uttered sends further home. All this in 150 lines!

Or, once more, consider the employment of narrative by this great poet. The *Tyrannus* might be again adduced, but let us turn instead to the *Antigone* and the *Trachiniae*. The speech of the messenger in the *Antigone*, the speeches of Hyllus and the Nurse in the *Trachiniae*, occur at the supreme crisis of the two dramas. Yet there is no sense of any retardation in the action by the report of what has been happening elsewhere. Much rather the audience are carried breathlessly along, while each speaker brings before their mental vision the scene of which he had himself been part. It is a drama within the drama, an action rising from its starting-point in rapid climax, swift, full, concentrated, until that wave subsides, and is followed by a moment of expectation. Nor is this all. The narrative of the messenger is overheard by Eurydice, that of Hyllus is heard by Deianira, that of Nurse by the chorus of Maidens. And in each case a poignancy of tragic significance is added by this circumstance, while the speech of the Messenger in the *Antigone*, and that of Hyllus in a yet higher degree, bind together in one the twofold interest of an action which might otherwise seem in danger of distracting the spectator's sympathies.

So profound is the contrivance, or, to speak more accurately, such is the strength of central feeling and conception, which secures the grace of unity in complexity to the Sophoclean drama.

The proportion of the lyrics to the level dialogue is considerably less on the average in Sophocles than in Aeschylus, as might be expected from the development of the purely dramatic element, and the consequent subordination of the chorus to the protagonist. In the seven extant plays the lyrical portion ranges from one-fifth to nearly one-third, being highest in the *Antigone* and lowest in the *Oedipus Tyrannus*. The distribution of the lyrical parts is still more widely diversified. In the *Electra*, for instance, the chorus has less to do than in the *Oedipus Tyrannus*, although in the former the lyrics constitute one-fourth, and in the latter only one-fifth of the whole. But then the part of Electra is favourable to lyrical outbursts, whereas it is only after the tragic change that Oedipus can appropriately pass from the stately senarius to the broken language of the dochmiac and the "lamenting" anapaest. The protagonists of the *Ajax* and the *Philoctetes* had also large opportunities for vocal display.

The union of strict symmetry with freedom and variety, which is throughout characteristic of the work of Sophocles, is especially noticeable in his handling of the tragic metres. In the iambics of his dialogue, as compared with those of Aeschylus, there is an advance which may be compared with the transition from "Marlowe's mighty line" to the subtler harmonies of Shakespeare. Felicitous pauses, the linking on of line to line, trisyllabic feet introduced for special effects, alliteration both hard and soft, length of speeches artfully suited to character and situation, adaptation of the caesura to the feeling expressed, are some of the points which occur most readily in thinking of his *senarii*. A minute speciality may be noted as illustrative of his manner in this respect. Where a line is broken by a pause towards the end and the latter phrase runs on into the following lines, elision sometimes takes place between the lines, *e.g.* (*Oed. Tyr.*, 332–333):—

> Ἐγὼ οὔτ' ἐμαυτὸν οὔτε σ' ἀλγυνῶ. τί ταῦτ'
> ἄλλως ἐλέγχεις;

This is called *synaphea*, and is peculiar to Sophocles.

He differentiates more than Aeschylus does between the metres to be employed in the κομμοί (including the κομματικά) and in the choral odes. The dochmius, cretic, and free anapaest are employed chiefly in the κομμοί. In the stasima he has greatly developed the use of logaoedic and particularly of glyconic rhythms, and far less frequently than his predecessor indulges in long continuous runs of dactyls or trochees. The light trochaic line –́ ⏑ – ⏑ –́ ⏑ –, so frequent in Aeschylus, is comparatively rare in Sophocles. If, from the very severity with which the choral element is subordinated to the purely dramatic, his lyrics have neither the magnificent sweep of Aeschylus nor the "linked sweetness" of Euripides, they have a concinnity and point, a directness of aim, and a truth of dramatic keeping, more perfect than is to be found in either. And even in grandeur it would be hard to find many passages to bear comparison with the second stasimon, or central ode, either of the *Antigone* (εὐδαίμονες οἷσι κακῶν) or the first *Oedipus* (εἴ μοι ξυνείη φέροντι). Nor does anything in Euripides equal in grace and sweetness the famous eulogy on Colonus (the poet's birthplace) in the *Oedipus Coloneus*.

Bibliography.—Sophocles was edited (probably from the Venetian MSS.) by Aldus Manutius, with the help of Musurus, in 1502. The Juntine editions in which the text of Aldus was slightly modified with the help of Florentine MSS. were published in 1522, 1547, respectively. An edition of the Scholia, very nearly corresponding to those on the margin of the Medicean or chief Laurentian MS. (La or L) has previously appeared at Rome in 1518. The first great modification of the text was due to Turnebus, who had access to the Parisian MSS.; but he was not fortunate in his selection. The earliest editors had been aware that the traditional arrangement of the metres was faulty, but little way had been made towards a readjustment. Now it so happens that the Parisian MS. T, which is a copy of the recension of Triclinius, an early 14th-century scholar, contains also the metrical views of the same editor; and, having found (as he erroneously supposed) a sound authority, Turnebus (1552) blindly adopted it, and was followed in this by H. Stephanus (1568), and by Canter in Holland (1579), who was the first to recognize the arrangement of the odes in strophe and antistrophe. The error was to a large extent corrected by Brunck (1786), who rightly preferred Par. A (2712), a 13th-century MS., belonging, as it happened, to the same family with Ven. 467, which Aldus had mainly followed. Thus after nearly three centuries the text returned (though with conjectural variations) into the former channel. Musgrave's edition was published posthumously in 1800, and Gilbert Wakefield had published a selection shortly before. Erfurdt in Germany then took up the succession, and his edition formed the basis of Hermann's, whose psychological method set the example of a new style of commentary which was adopted by Wunder. A new era commenced with Peter Elmsley's collation of the Laurentian MS. (made in 1818, but only published in full after his death). His transcription of the Scholia still exists in the Bodleian Library. The most important German commentaries

since Hermann's have been those of Schneidewin, G. Wolff and Wecklein. L. Campbell's edition of the plays and fragments (1871–1881) was quickly followed by Jebb's edition of the seven plays (1881–1896). Editions of one or more dramas most worth consulting are Elmsley's *Oedipus Tyrannus* and *Oedipus Coloneus*, Böckh's *Antigone*, Lobeck's *Ajax*, J. W. Donaldson's *Antigone*, O. Jahn's *Electra* and J. William White's *Oed. Tyr.* A monograph on the *Antigone* by Kaibel is also well worth mentioning. Translations: in verse, by Francklin, Potter, Dale, Plumptre, L. Campbell, Whitelaw; in prose by R. C. Jebb. The chief German translations are those of Solger (1824), Donner (1839), Hartung (1853) and Thudichum. The French prose translation by Leconte de Lisle, and the Italian in verse by Bellotti deserve special mention. The *Antigone* was produced at Berlin with Mendelssohn's music in 1841 and the *Oedipus Coloneus* in 1845. They have been reproduced in English several times—the *Antigone* notably with Helen Faucit (Lady Martin) in the title-rôle in 1845. The *Oedipe Roi* (trans. La Croix) and the *Antigone* (trans. Vacquerie) have been frequently performed in Paris. A performance of the *Oedipus Tyrannus* in Greek at Harvard University, U.S.A. (1880), was remarkably successful. Of dissertations immediately devoted to Sophocles those of Lessing, Patin, Dronke and Evelyn Abbott (in *Hellenica*) are especially noteworthy. (L. C.)

SOPHOMORE, the name in American universities (corresponding to "sophister" at Cambridge, England, and Trinity College, Dublin) for a student who has completed his first year of academic studies. It is a corruption of the earlier "sophimore," due to a supposed derivation from σοφός, wise, and μῶρος, foolish, alluding to the air of wisdom assumed by students after their freshman's year was concluded. The earlier word "sophimore" (cf. "Laws of Yale Coll., 1774," in Hall's *College Words*) represents "sophismer," a doublet of "sophister," and means an arguer or debater (cf. the Cambridge use of "wrangler"), and is formed from the Greek σόφισμα, sophism, an ingenious or captious argument.

SOPHRON, of Syracuse, writer of mimes, flourished about 430 B.C. He was the author of prose dialogues in the Doric dialect, containing both male and female characters, some serious, others humorous in style, and depicting scenes from the daily life of the Sicilian Greeks. Although in prose, they were regarded as poems; in any case they were not intended for stage representation. They were written in pithy and popular language, full of proverbs and colloquialisms. Plato is said to have introduced them into Athens and to have made use of them in his dialogues; according to Suïdas, they were Plato's constant companions, and he even slept with them under his pillow. Some idea of their general character may be gathered from the 2nd and 15th idylls of Theocritus, which are said to have been imitated from the Ἀκέστριαι and Ἰσθμιάζουσαι of his Syracusan predecessor. Their influence is also to be traced in the satires of Persius. The fragments will be found in H. L. Ahrens's *De graecae linguae dialectis* (1843), ii. (app.). Latest edition by C. J. Botzon (1867); see also his *De Sophrone et Xenarcho mimographis* (1856).

SOPHRONIUS, Greek "sophist" and theological writer, was born at Damascus. For many years he was a monk in the monastery of Theodosius, near Jerusalem, removed to Alexandria, whence he was driven out by the advance of the Persians, and finally settled in Palestine, where he became (634) successor of Modestus in the patriarchate of Jerusalem. After his elevation he showed himself a staunch supporter of orthodox principles and one of the most determined opponents of the Monothelites. In 636, when Jerusalem surrendered to the Arabs under Omar, he succeeded in obtaining important concessions for the Christians in the exercise of their worship. He did not long survive the capture of the city, and after his death the see remained unfilled for 29 years. Sophronius was a prolific writer, both in prose and verse, in various departments of literature. His chief work is a long account of the Egyptian saints and martyrs Cyrus and John, and of the miraculous cures effected by them, valuable for its information concerning the topography of Egypt. The *Life* of Mary of Egypt, who abandoned immorality for a life of the strictest penance in Palestine for 48 years, is generally attributed to him. He was also the author of anacreontic odes, hymns, and epigrams.

Works in J. P. Migne, *Patrologia graeca*, lxxxvii., and list in Fabricius, *Bibliotheca graeca*, ix. 162; see also L. de St Aignan, *Vie de Sophronius* (Orleans, 1884); C. Krumbacher, *Geschichte der byzantinischen Litteratur* (1897); and for Sophronius and Omar, Gibbon, ch. 51.

SOPRANO (a variant of Ital. *sovrano*, supreme, sovereign, Late Lat. *superanus*, from *super*, above), the term applied in music to the highest natural range of the human voice, and often restricted to that range in the female voice, "treble" being used of a boy's voice. Male *soprani*, either natural or artificially produced, as formerly in the *castrati* of the papal choirs (see EUNUCH), are also found. The female voice whose range is intermediate between that of a soprano or a contralto is termed "mezzo-soprano."

SOPRON (Ger. *Oedenburg*; Med. Lat. *Sopronium*), a town of Hungary, capital of the county of the same name, 140 m. W. of Budapest by rail. Pop. (1900), 30,628, about 60% Germans. It lies in an extensive valley enclosed on all sides by the outskirts of the Rosalien mountains, a group belonging to the eastern outliers of the Alps. In the principal square are the Benedictine church, built at the end of the 13th century and restored in the 15th century, and the town hall, completed in 1894. The Dominican church, built in 1674; the church of St Michael, in the Gothic style, completed in 1484, the most interesting church in the town; and the old tower, 200 ft. high, are all worth notice. Sopron has a thriving industry in sugar, soap, vinegar, bell-founding and machinery, and it carries on an active trade in cereals, fruit and wine. Large cattle markets are also held here. Within the county a good quality of wine is produced, especially near the little town of Ruszt (pop. 1608) and at the village of Balf (Ger., *Wolfs*) on the shores of the Neusiedler lake. In the neighbourhood of Sopron is the Brennberg, with extensive coal-mines. Sopron was a Roman colony under the name of *Scarabantia*. It was afterwards occupied by German settlers and became a royal free town in the 11th century. Matthias Corvinus granted the town special privileges in 1464. An important Diet of Hungarian Protestants took place here in 1681.

About 12 m. north, at the foot of the Leitha mountains, lies the town of Kismarton (Ger. *Eisenstadt*; pop., 2951), which contains a magnificent castle of the Esterhazy family, built in 1683 and enlarged in 1805. About 10 m. north-west lies Nagymarton (Ger. *Mattersdorf*; pop., 3789); and not far from it, on the frontier of Austria, the well-preserved castle of Forchtenstein, the cradle of the Esterhazy family. About 12 m. east, not far from the Neusiedler lake, lies Esterhaza, with a beautiful castle in the French Renaissance style, belonging to Count Esterhazy. About 9 m. south-east lies the village of Nagyczenk (Ger. *Zinkendorff*), with the castle of the Szechenyi family.

SORA, a city of Campania, Italy, in the province of Caserta, 77 m. N. by W. of that town on the railway between Roccasecca and Avezzano, 920 ft. above sea-level. Pop. (1901), 6,050 (town); 16,022 (commune). It is built in a plain on the banks of the Liris. This part of the valley is the seat of some important manufactures, especially of paper-mills. The original cathedral, consecrated by Pope Adrian IV. in 1155, was destroyed by the earthquake of 1634. On the precipitous rock above the town (1768 ft.) which guards the Liris valley and the entrance to the Abruzzi are remains of polygonal walls; here, possibly, was the citadel of the original Volscian town. There are also remains of medieval fortifications. In the town itself there are no remains of antiquity nor buildings of interest. The district around Sora is famous for the costumes of its peasants.

Sora, an ancient Volscian town, was thrice captured by the Romans, in 345, 314 and 305 B.C., before they managed, in 303, by means of a colony 4000 strong, to confirm its annexation. In 209 it was one of the colonies which refused further contributions to the war against Hannibal. By the lex Julia it became a *municipium*, but under Augustus it was colonized by soldiers of the legio IV. Sorana, which had been mainly enrolled there. It belonged technically to *Latium Adjectum*. The castle of Sorella, built on the rocky height above the town, was in the middle ages a stronghold of some note. Charles I. of Anjou made Sora a duchy for the Cantelmi; it was afterwards seized by Pius II., but, being restored to the Cantelmi by Sixtus IV., it ultimately passed to the Della Rovere of Urbino. Against Caesar Borgia the city was heroically defended by Giovanni di Montefeltro. It was purchased by Gregory XIII. for 11,000 ducats and bestowed on the Buoncompagni, the ancestors of the line of Buoncompagni-Ludovisi. In ancient times Sora was the birthplace of the Decii, Attilius Regulus, and Lucius Mummius; and among its later celebrities is Cardinal Baronius. (T. As.)

SORACTE, a mountain in the province of Rome, Italy. It is a narrow, isolated limestone ridge, some 5 m. S.E. of Civita Castellana, and $3\frac{1}{2}$ m. in length. The highest summit is 2267 ft. above sea-level; just below it is a monastery removed there from the summit in 1835; it was originally founded about 748 by Carloman, son of Charles Martel (the altar has, indeed, fragments of sculptures of this period), and until modern times was occupied by Trinitarian monks. On the actual summit is a church. Owing to the isolated position of the mountain the view is magnificent, and Soracte is a conspicuous object in the landscape, being visible from Rome itself. It is thus mentioned by Horace ("vides ut alta stet nive candidum Soracte?" *Carm.* i. 9), and Virgil, who mentions Apollo as its guardian deity, though no traces of his temple exist; and in reality it was sacred to Dis Pater and the gods of the lower world. At the bottom of the mountain on the east is a disused limestone quarry. The village of S. Oreste at the south-east end of the ridge owes its name to a corruption of the ancient name. In the communal palace is a fine processional cross of the 11th century in the Byzantine style (see *Römische Quartalschrift*, 1905, 209—Archäologie).

SORANUS, Greek physician, born at Ephesus, lived during the reigns of Trajan and Hadrian (A.D. 98–138). According to Suïdas, he practised in Alexandria and subsequently in Rome. He was the chief representative of the school of physicians known as "methodists." Two treatises by him are extant: *On Fractures* (in J. L. Ideler, *Physici et medici minores*, i. 1841) and *On Diseases of Women* (first published in 1838, later by V. Rose, in 1882, with a 6th-century Latin translation by Moschio, a physician of the same school). Of his most important work (*On Acute and Chronic Diseases*) only a few fragments in Greek remain, but we possess a complete Latin translation by Caelius Aurelianus (5th century). The *Life of Hippocrates* (in Ideler) probably formed one of the collection of medical biographies by Soranus referred to by Suïdas, and is valuable as the only authority for the life of the great physician, with the exception of articles in Suïdas and Stephanus of Byzantium (*s.v.* Κῶς). The *Introduction to the Science of Medicine* (V. Rose, *Anecdota graeca*, ii. 1870) is considered spurious.

See article by J. Hahn, in Dechambre's *Dictionnaire encyclopédique des sciences médicales*, 3rd series, tom. 10; W. Christ, *Geschichte der griechischen Litteratur* (1898); J. Ilberg, *Die Überlieferung der Gynaekologie des Soranos von Ephesos* (Leipzig, 1910).

SORANUS, BAREA, Roman senator, lived in the reign of Nero. His gentile name was possibly Servilius. In 52 he was consul suffectus, and (perhaps in 61) proconsul of Asia. The upright and considerate manner in which he treated the provincials won him their affection, but at the same time brought upon him the hatred of Nero, who felt specially aggrieved because Soranus had refused to punish a city which had defended the statues of its gods against the Imperial commissioners. Soranus was accused of intimacy with Rubellius Plautus (another object of Nero's hatred), and of endeavouring to obtain the goodwill of the provincials by treasonable intrigues. One of the chief witnesses against him was Egnatius Celer of Berytus, his client and former tutor. Soranus was condemned to death (in 65 or 66), and committed suicide. His daughter Servilia, who was charged with having consulted the sorcerers, professedly in regard to her father's fate, but in reality with evil designs against the emperor, was involved in his downfall. The accuser, who was condemned to death in the reign of Vespasian for his conduct on this occasion, is a standing example of ingratitude and treachery.

Tacitus, *Annals*, xvi. 30, 32; *Hist.* iv. 10; Juvenal iii. 116; Dio Cassius lxii. 26.

SORAU, a town of Germany, in the Prussian province of Brandenburg, on the Sorebach, 54 m. S.E. of Frankfort-on-Oder by rail, and at the junction of lines to Cottbus and Görlitz. Pop. (1905), 16,410. One of the oldest towns in Lower Lusatia, Sorau contains a number of ancient buildings, among which the most prominent are several of the churches (one dating from 1204), the town hall, built in 1260, and the old palace of 1207 (now a prison). The new palace, erected in 1711 by Count Erdmann II. of Promnitz, is utilized for government offices. The varied manufactures of the town comprise cloth, linen, wax candles, starch, glass and porcelain.

Sorau is said to have existed in 840, and to have belonged to the abbey of Fulda till the 12th century. It received civic rights in 1260. With the surrounding district, known as the barony of Sorau, it became the seat of successive noble families; and in 1400 it was united with the barony of Triebel. The last Count of Promnitz, whose ancestor had purchased both baronies from Frederick of Bohemia in 1556, sold them in 1765 to the elector of Saxony for an annuity of 12,000 thalers (£1800). In 1815 Saxony ceded them to Prussia.

See Worbs, *Geschichte der Herrschaft Sorau und Triebel* (Sorau, 1826).

SORBONNE, the name given originally to the college founded by Robert de Sorbon in Paris; hence applied afterwards popularly to the theological faculty, and so to the institution which is now the seat of the Académie of that city (see UNIVERSITIES). The Sorbonne owes its origin and its name to Robert of Sorbon, near Reims (1201–1274), who went to Paris about the beginning of the reign of St Louis in order to qualify for the priesthood, attained high repute by his sanctity and eloquence, and was appointed by the king to be his confessor. Assisted by royal liberality, he built a modest establishment in which were accommodated seven priests charged with the duty of teaching theology gratuitously; to this he added a college of preparatory studies, all under the direction of a provisor, under whom was an annual prior who had the actual management. The new institution was authorized in 1252 by a deed signed by Queen Blanche, on behalf of Louis IX. (who was in Palestine); and in 1257 a site was given by the king in the heart of the Latin quarter. It was declared "useful to religion" by Pope Alexander IV. in 1259, and papal bulls authorizing and confirming the college were granted in 1263 and 1268. Destined originally for poor students (and called *domus magistrorum pauperrima*, "most poor house of masters"), the Sorbonne soon became a meeting-place for all the students of the university of Paris, who resorted thither to hear the lectures of the most learned theologians of the period—Guillaume de Saint Amour, Eudes de Douai, Laurent l'Anglais, Pierre d'Ailly. At the close of the century it was organized into a full faculty of theology, and under this definite form it conferred bachelors', licentiates' and doctors' degrees, and the severity of its examinations gave an exceptional value to its diplomas. The so-called "thèse sorbonique," instituted towards the beginning of the 14th century, became the type of its order by the length and difficulty of its tests. Ultimately the professors of the Sorbonne came to be resorted to not only for lectures and examinations, but also for dogmatic decisions and judgments in canon law; the clergy of France and of the whole Catholic world had recourse to them in difficult cases, and the Curia Romana itself more than once laid its doubts before them, giving them the title of "Concilium in Gallia subsistens." To the Sorbonne belongs the glory of having introduced printing into France in 1469: within its precincts it assigned quarters for Ulric Gering and two companions in which to set up their presses. The Sorbonne took a leading part in the religious discussions which agitated France during the 16th and 18th centuries, and its influence thus inevitably extended to political questions. During the insanity of Charles VI. it helped to bring about the absolution of Jean Sans-Peur for the assassination of the duke of Orleans

Shortly afterwards it demanded and supported the condemnation of Joan of Arc; during the Reformation it was the animating spirit of all the persecutions directed against Protestants and unbelievers: without having advised the massacre of St Bartholomew, it did not hesitate to justify it, and it inflamed the League by its vigorous anathemas against Henry III. and the king of Navarre, hesitating to recognize the latter even after his abjuration. From this point dates the beginning of its decadence, and when Richelieu in 1626 ordered the reconstruction of its church and buildings the following prophetic couplet was circulated—

"Instaurata ruet jamjam Sorbona. Caduca
Dum fuit, inconcussa stetit; renovata peribit."

The declaration of the clergy in 1682, which it subscribed, proved fatal to its authority with the Curia Romana; it revived for a short time under Louis XV. during the struggle against Jansenism, but this was its last exploit; it was suppressed like the old universities in 1792.

When the university of France was organized in 1808 the Sorbonne became the seat of the *académie* of Paris; and between 1816 and 1821 the faculties of theology (since disappeared), science and literature were installed there. The university library was transferred to the Sorbonne in 1823. In 1868 was organized the École des Hautes Études, and in 1897 the École des Chartes also found its home at the Sorbonne.

In 1852 the Sorbonne was made the property of the city of Paris; a reconstruction of the buildings, projected by Napoleon III., was begun in 1884, under the architectural direction of Nénot, and completed in 1889. The old church containing the tomb of Richelieu was retained on account of its artistic merit. This new Sorbonne is one of the finest university edifices in the world, and has developed into the chief French centre of learning.

SORBS, the tribal name of the Slavonic people, whom the Germans call Wends in Lusatia (Lausitz); they call themselves Serbs or Lužičane. Their country includes the western extremity of the kingdom of Saxony and parts of the districts of Hoyerswerda, Muskau, Kottbus, Kalau, Spremberg and Sorau in Prussia; they are now surrounded on all sides by Germans, but they formerly had them as neighbours only on the west along the Fulda, while on the north towards Köpenick they marched with the Lutiči, on the east with the Poles and Silesians along the Queiss and Bobr, and on the south were separated from the Bohemians by the mountains that now make the Austrian frontier. The Sorbs are divided into High and Low along a line from Sagan to Muskau and Spremberg. They are in all about 180,000 in number; 80,000 Low Sorbs and 40,000 of the 100,000 High Sorbs are in Prussia, and 60,000 High Sorbs in Saxony. These have gained definite rights for their language in school and administration, so that Bautzen (Budyšin), their capital, is the intellectual centre not only for Saxon subjects, but for all High Sorbs and to a great extent for Low Sorbs. The first monuments of both dialects belong to the Reformation period, these being translations of Luther's Catechism by Warichius and Moller. Some Sorbs are Protestants, though the Saxon Sorbs are mostly Roman Catholics. Early in the 19th century the High Sorbs had a revival under the leadership of F. A. Klin, a lawyer and politician; A. Seidler, a considerable poet, and S. E. Smoler, an ethnographer and publicist. More recent writers are J. Ćišinsk and J. Radyserb. A *Macica* or Literary and Linguistic Society was founded in 1847, and publishes a *Časopis* or Periodical. Meanwhile Low Sorb has remained almost uncultivated owing to the pressure of the Prussian administration.

The two dialects stand between Polish and Čech: they have lost the nasal vowels, have the accent on the first syllable, and make *tj* into *č*, *dj* into *z*, like Čech, but they retain *x* and *y* and, like Polish, have *grod* for Čech *grad*. High Sorb has *h*, Low the original *g*. They have kept the old aorist and dual. Sorb is usually printed in German blackletter variously adapted; the *Macica* publishes some books spelt after the Čech system.

SORBY, HENRY CLIFTON (1826–1908), English microscopist and geologist, was born at Woodbourne near Sheffield on the 10th of May 1826. He early developed an interest in natural science, and one of his first papers related to the excavation of valleys in Yorkshire. He subsequently dealt with the physical geography of former geological periods, with the wave-structure in certain stratified rocks, and the origin of slaty cleavage. He took up the study of rocks and minerals under the microscope, and published an important memoir *On the Microscopical Structure of Crystals* in 1858 (*Quart. Journ. Geol. Soc.*). In England he was one of the pioneers in petrography; he was awarded the Wollaston medal by the Geological Society of London in 1869, and when president of the society he published in his addresses the results of original researches on the structure and origin of limestones, and of the non-calcareous stratified rocks (1879–1880). He had previously been president of the Royal Microscopical Society. He wrote on the construction and use of the micro-spectroscope in the study of animal and vegetable colouring matter, and in later essays he dealt with such varied subjects as the microscopical structure of iron and steel, and the temperature of the water in estuaries. He also applied his skill in making preparations of invertebrate animals for lantern-slides. In 1882 he was elected president of Firth College, Sheffield. He died on the 9th of March 1908.

SORCERY, magic, enchantment, witchcraft; the use of supposed supernatural powers by the agency of evil spirits called forth by spells, incantations, &c., on the part of the magician, sorcerer or witch. The word meant originally divination by means of the casting or drawing of lots, and is derived from the O. Fr. *sorcerie*, *sorcier*, a sorcerer, Med. Lat. *sortiarius*, one who practises divination by lots, *sortes* (see MAGIC, DIVINATION and WITCHCRAFT).

SORDELLO, a 13th-century Italian troubadour, born at Mantua, who is praised by Dante in the *De vulgari eloquio*, and in the *Purgatorio* made the type of patriotic pride. He is also the hero of a well-known poem by Robert Browning. The real Sordello, so far as we have authentic facts about his life, hardly seems to justify these idealizations, though he was the most famous of the Italian troubadours. About 1220 he appears at Florence in a tavern brawl; and in 1226, while at the court of Richard of Bonifazio at Verona, he abducts his master's wife, Cunizza, at the instigation of her brother, Ezzelino da Romano. The scandal resulted in his flight (1229) to Provence, where he seems to have been for some time. He entered the service of Charles of Anjou, and probably accompanied him (1265) on his Naples expedition; in 1266 he was a prisoner in Naples. The last documentary mention of him is in 1269, and he is supposed to have died in Provence. His didactic poem, *L'Ensenhamen d'onor*, and his love songs and satirical pieces have little in common with Dante's presentation, but the invective against negligent princes which Dante puts into his mouth in the 7th canto of the *Purgatorio* is more adequately paralleled in his *Serventese* (1237) on the death of his patron Blacatz, where he invites the princes of Christendom to feed on the heart of the hero.

For Sordello's life and works see the edition of Cesare de Lollis (Halle, 1896); for Browning's poem see Stopford Brooke's *Browning* (1902).

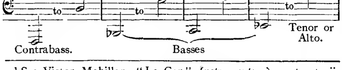
SORDINO, SORDONI, SORDUNI, Italian terms somewhat promiscuously applied by various writers (1) to contrivances for damping or muting wind, string and percussion instruments (*Sordini*); (2) to a family of obsolete wind instruments blown by means of a double reed (*Sordoni* or *Sordun*); (3) to a stringed instrument. To these must also be added the *Surdellina* or

Sordellina, a kind of musette invented (see BAGPIPE) in Naples in the 17th century, and evidently named after class 2.

1. Under the Italian term *sordini* are comprised the dampers used with stringed instruments, such as the violin, and the dampers of keyboard instruments, all well known, and described with the instruments themselves. As a certain amount of misconception exists concerning the *sordini* (Fr. *sourdines*, Ger. *Dämpfer*), used from the 16th century with the trumpet and later with the horn, they may be briefly described. It would appear that the art has almost been lost of making mutes for trumpets and French horns, which should affect the timbre only, giving it a certain veiled mysterious quality similar to that of the *sons bouchés* or hand-stopped notes, but affecting the pitch not at all. We read that when it is necessary to produce this peculiar timbre on the valve-horn, as for instance in Wagner's *Rheingold*, the rise of a semi tone in pitch caused by the introduction of the mute or the hand into the bell of the horn must be compensated by means of the second piston which lowers the pitch a semi-tone.[1]

If the sordino used early in the 17th century had had this effect of raising the pitch, the fact would have been stated by such writers as Mersenne and Praetorius; it would, moreover, have rendered the mute useless with instruments on which no sort of compensation was possible. H. Domnich[2] and J. Fröhlich,[3] however, describe the sordino which leaves the pitch unaffected: it consisted of a hollow cone of wood or cardboard, truncated at the apex to allow the air to pass through and escape through a hole in the base. The bore of the instrument thus continued through the cone of the mute was the essential point, and the proportions to be maintained between the diameters of the two bores were also, no doubt, of importance. Domnich expressly states that it was when Hampel substituted a plug of cotton-wool (therefore solid and providing no central passage for the air) for the mute, that he found the pitch of the horn raised a semi-tone. Domnich's evidence is of value, for his father was a horn-player contemporary with Hampel, and he himself was the intimate friend and colleague of Punto, Hampel's most celebrated pupil.

2. The *sordun* or *sordoni* family are often confused with the dolcians (Fr. *courtaud*, Eng. *single curtail*, Ger. *Kort* or *Kortholt*), from which, however, they differed radically. This difference was not understood by Michael Praetorius, who acknowledges his mystification. The contra-bass sordun, he says, hardly half the length of the contra-fagotto, is yet practically of the same pitch, which is astonishing since the bore is only double once upon itself as in the fagotto. The kort likewise is of the same size as the bass sordun, and yet in pitch it is but a tenor. The following description of the construction and acoustic properties of the sordoni will clear up the mystery. The body consisted of a cylinder of wood in which were cut two parallel channels of narrow cylindrical bore, communicating with each other at the bottom through a bend, but not with ambient air. At the top of the cylinder was fitted a double-reed mouthpiece giving access to the column of air at one end of the bore, while the other was vented through a small hole in the side, similar to the finger-holes; in the tenor, bass and contra members of the family, the reed was attached to a curved brass crook similar to that of the fagotto. So far the description would almost apply to the dolcian also, but in the latter there is the radical difference that the bore of the channels is conical, so that it has the acoustic properties of the open pipe. The sordun, however, having a cylindrical bore, has the acoustic properties of the stopped pipe, *i.e.* the sound waves are twice the length of the pipe, so that to produce a sound of any given pitch, for instance for C, the bore need only be half the length, *i.e.* 4 ft. long. Overblowing, on the sordoni, moreover, produced as first harmonic (the only one required for reed-blown instruments in order to produce the diatonic scale for the second octave) not the octave, but the twelfth, or number 3 of the series. This accounts for the fact that instruments of the fagotto and dolcian type require but 6 or 7 holes to give the diatonic scale throughout the compass, whereas the sordoni require 11 or 12 holes. Praetorius states that those figured by him (Plate XII.) have 12 open holes, and that some specimens have in addition two keys; a hole is also bored through the bottom of the instrument to allow the moisture condensed from the breath to be shaken out. The 12 holes are stopped by means of fingers and thumbs and by the ball of the hand or the fleshy underpart of the joints of the fingers. The compass of the 5 sizes of sordoni was as follows:—



[1] See Victor Mahillon, "Le Cor," *Instruments à vent*, pt. ii. (Brussels and London, 1907), pp. 34 and 53.

[2] *Méthode de premier et de second cor* (Paris, *c.* 1807), pp. 3 and 4.

[3] Vollständige theor.-prakt. Musiklehre für alle bei dem Orchester gebräuchliche Instrumente (Cologne and Bonn, *c.* 1811).

Two sourdines belonging to the Museum of the Brussels Conservatoire, said to be facsimiles of some instruments belonging to the emperor Maximilian I.'s band, are reproduced in Captain C. R. Day's *Descriptive Catalogue of Musical Instruments* (London, 1891). They differ slightly in construction from the Italian instruments described by Praetorius. The straight crook is set in the side of the instrument, almost at right angles, the top of the cylinder is surmounted by a cap, and there are but 6 open holes, the rest being covered by brass keys in wooden boxes. The pitch of these instruments lies within a semi-tone of that of the contra-bass and bass of Praetorius. (K. S.)

SOREL, AGNES (*c.* 1422–1450), mistress of King Charles VII. of France, was born of a family of the lesser nobility at Fromenteau in Touraine. While still a girl she was attached to the service of Isabel of Lorraine, queen of Sicily, wife of René of Anjou, the brother-in-law of Charles VII. From 1444 until her death in 1450 she was the acknowledged mistress of the king, the first woman to hold that semi-official position which was to be of so great importance in the subsequent history of the old régime. Her ascendancy dated from the festivals at Nancy in 1444, the first brilliant court of Charles VII. Here her great beauty captivated the king, whose love for her remained constant until her death. He gave her wealth, castles and lands, and secured for her the state and distinction of a queen. This first public recognition of his mistress by a king of France scandalized all good people and awakened jealousy and intrigue. Her sudden death from dysentery, shortly after the birth of her fourth child, was accordingly attributed to poison. Burgundian historians even openly accused the Dauphin, afterwards Louis XI., of her death, and later the enemies of Jacques Cœur, in their search for crimes to be brought against him, used this rumour to charge him with the one crime most likely to turn the king against him. Her heart was buried in the abbey of Jumièges, her body in the collegiate church of Loches. Contemporary writers all bear witness to her extraordinary beauty, but no genuine portraits of her have come down to us.

Legend has made an entirely different character of this first official mistress of the French kings. The date of her birth was placed at about 1409, her liaison with the king dated from 1433. Then, so the story ran, she drew him from his indolence, continuing the work of Joan of Arc, both by nerving the king to warlike enterprises—she did apparently induce him to take part personally in the conquest of Normandy—and by surrounding him with that band of wise advisers who really administered France during her ascendancy. Recent investigation has exploded this romantic story by simply showing that Charles VII. had not met her until ten years later than in the legend. Instead of being his sole good angel, she seems rather to have demoralized the king, who, hitherto chaste, henceforth gave himself up to courtesans. Yet she favoured the best advisers of the king, and at least in this deserved the gratitude of the realm. Pierre de Brézé seems especially to have used Agnes to gain his ascendancy over the king.

See A. Vallet de Viriville's articles in *Bibliothèque de l'École des chartes* (3rd series, tom. i.); and R. Duquesne, *Vie et aventures galantes de la belle Sorel* (1909).

SOREL, ALBERT (1842–1906), French historian, was born at Honfleur on the 13th of August 1842. He was of a characteristically Norman type, and remained all his life a lover of his native province and its glories. His father, a rich manufacturer, would have liked him to succeed to the business, but his literary vocation prevailed. He went to live in Paris, where he studied law, and after a prolonged stay in Germany entered the Foreign Office (1866). He had strongly-developed literary and artistic tastes, was an enthusiastic musician, even composing a little, and wrote both verses and novels, which appeared a little later (*La Grande Falaise*, 1785–1793, in 1871, *Le Docteur Egra* in 1873); but he did not go much into society. He was anxious to know and understand present as well as past events, but he was above all things a student. In 1870 he was chosen as secretary by M. de Chaudordy, who had been sent to Tours as a delegate in charge of the diplomatic side of the problem of national defence; in these affairs he proved himself a most valuable collaborator;

he was unremitting in his labours, full of *finesse*, good temper and excellent judgment, and at the same time so discreet that we can only guess at the part he played in these terrible crises. After the war, when Boutmy founded the *École libre des sciences politiques*, Sorel was appointed to teach diplomatic history (1872), a duty which he performed with striking success. Some of his courses have formed books: *Le Traité de Paris du 20 novembre 1815* (1873); *Histoire diplomatique de la guerre franco-allemande* (1875); we may also add the *Précis du droit des gens* which he published (1877) in collaboration with his colleague Théodore Funck-Brentano. In 1875 Sorel left the Foreign Office and became general secretary to the newly-created office of the *Présidence du sénat*. Here again, in a congenial position where, without heavy responsibilities, he could observe and review affairs, he performed valuable service, especially under the presidency of the duc d'Audiffred Pasquier, who was glad to avail himself of his advice in the most serious crises of internal politics. His duties left him, however, sufficient leisure to enable him to accomplish the great work of his life, *L'Europe et la révolution française*. His object was to do over again the work already done by Sybel, but from a less restricted point of view and with a clearer and more calm understanding of the chess-board of Europe. He spent almost thirty years in the preparation and composition of the eight volumes of this history (vol. i., 1885; vol. viii., 1904). For he was not merely a conscientious scholar; the analysis of the documents, mostly unpublished, on French diplomacy during the first years of the Revolution, which he published in the *Revue historique* (vol. v.–vii., x.–xiii.), shows with what scrupulous care he read the innumerable despatches which passed under his notice. He was also, and above all things, an artist. He drew men from the point of view of a psychologist as much as of a historian, observing them in their surroundings and being interested in showing how greatly they are slaves to the fatality of history. It was this fatality which led the rashest of the Conventionals to resume the tradition of the Ancien Régime, and caused the revolutionary propaganda to end in a system of alliances and annexations which carried on the work of Louis XIV. This view is certainly suggestive, but incomplete; it is largely true when applied to the men of the Revolution, inexperienced or mediocre as they were, and incompetent to develop the enormous enterprises of Napoleon I. In the earlier volumes we are readily dominated by the grandeur and relentless logic of the drama which the author unfolds before our eyes; in the later ones we begin to make some reservations; but on the whole the work is so complete and so powerfully constructed that it commands our admiration. Side by side with this great general work, Sorel undertook various detailed studies more or less directly bearing on his subject. In *La Question d'Orient au XVIII^e siècle, les origines de la triple alliance* (1878), he shows how the partition of Poland on the one hand reversed the traditional policy of France in eastern Europe, and on the other hand contributed towards the salvation of republican France in 1793. In the *Grands écrivains* series he was responsible for *Montesquieu* (1887) and *Mme de Staël* (1891); the portrait which he draws of Montesquieu is all the more vivid for the intellectual affinities which existed between him and the author of the *Lettres persanes* and the *Esprit des lois*. Later, in *Bonaparte et Hoche en 1797*, he produced a critical comparison which is one of his most finished works (1896); and in the *Recueil des instructions données aux ambassadeurs* he prepared vol. i. dealing with Austria (1884). Most of the articles which he contributed to various reviews and to the *Temps* newspaper have been collected into volumes: *Essais d'histoire et de critique* (1883), *Lectures historiques* (1894), *Nouveaux essais d'histoire et de critique* (1898), *Études de littérature et d'histoire* (1901); in these are to be found a great deal of information and of ideas not only about political men of the last two centuries, but also about certain literary men and artists of Normandy. Honours came to him in abundance, as an eminent writer and not as a public official. He was elected a member of the Académie des sciences morales et politiques (December 18, 1889) on the death of Fustel de Coulanges, and of the Académie française (1894) on the death of Taine. His speeches on his two illustrious predecessors show how keenly sensible he was of beauty, and how unbiased was his judgment, even in the case of those whom he most esteemed and loved. He had just obtained the great Prix Osiris of a hundred thousand francs, conferred for the first time by the Institut de France, when he was stricken with his last illness and died at Paris on the 29th of June 1906.

(C. B*.)

SOREL, CHARLES, Sieur de Souvigny (1597–1674), French novelist and miscellaneous writer, was born in Paris about 1597. Very little is known of his life except that in 1635 he was historiographer of France. He wrote on science, history and religion, but is only remembered by his novels. He tried to destroy the vogue of the pastoral romance by writing a novel of adventure, the *Histoire comique de Francion* (1622). The episodical adventures of Francion found many readers, who nevertheless reserved their admiration for the *Astrée* it was intended to ridicule. Sorel decided to make his intention unmistakable, and in *Le Berger extravagant* (3 vols., 1627) he wrote a burlesque, in which a Parisian shop-boy, his head turned by sentiment, chooses an unprepossessing mistress and starts life as a shepherd with a dozen sheep on the banks of the Seine. Sorel did not succeed in founding the novel of character, and what he accomplished was more in the direction of farce, but he struck a shrewd blow at romance. Among his other works are *Polyandre* (1648) and *La Connaissance des bons livres* (1673). He died in Paris on the 8th of March 1674.

SOREL, a town and port of entry of Quebec, Canada, capital of Richelieu county, 42 m. N.E. of Montreal, at the confluence of the Richelieu and St Lawrence rivers. Pop. (1901), 7057. It is on the Grand Trunk and the Quebec Southern railways, and is a port of call for the Montreal and Quebec river steamers. It contains iron and leather manufactories, and shipbuilding is carried on. It occupies the site of a fort built in 1665 by A. de Tracy to guard the route by way of the Richelieu to Lake Champlain and the Hudson, and is named after the first commandant of the garrison.

SORGHUM, a genus of grasses belonging to the tribe Andropogoneae, and including one of the most important tropical grains, *Sorghum vulgare*, great millet, Indian millet or Guinea corn. In India it is known as *jawari* (Hindustani), *jowari* (Bengali), *cholum* (Tamil), and *jonna* (Telugu), and in the West Indies as Negro or Guinea Corn. It is a strong grass, growing to a height of from 4 to 8 or even 16 ft.; the leaves are sheathing, solitary, and about 2 in. broad and 2½ ft. in length; the panicles are contracted and dense, and the grains, which are enclosed in husks and protected by awns, are round, hard, smooth, shining, brownish-red, and somewhat larger than mustard seeds. The plant is cultivated in various parts of India and other countries of Asia, in the United States, and in the south of Europe. Its culms and leaves afford excellent fodder for cattle; and the grain, of which the yield in favourable situations is upwards of a hundredfold, is used for the same purposes as maize, rice, corn and other cereals.

Sorghum vulgare.

Speaking of its cultivation, Eduard Hackel (in his article on "Grasses" in *Die natürlichen Pflanzenfamilien*) says the culture of Sorghum probably had its origin in Africa, where a variety known as durra is now cultivated over the entire continent, and has become the most important cereal; the natives also chew the stem, which contains sugar. In Europe it is raised less for bread than for mechanical purposes; the panicles are made into the so-called rice-brooms and into brushes. In Germany it is occasionally raised for green fodder. From the fruit the Kaffirs make an alcoholic drink, *Tialva*, and the negroes one known as *Merisa*. Allied species are *S. bicolor*, much valued in India as a forage-plant, and *S. saccharatum*, commonly called sorghum or Chinese sugar-cane, which is extensively cultivated in China, North India and Africa. The latter species is grown in America chiefly for the manufacture of molasses from its juice, and in France as a source of alcohol.

A full account of the cultivation and use of the species in India will be found in Sir G. Watt's *Dictionary of the Economic Products of India* (1893).

SORIA, a province of Spain, formed in 1833 of districts belonging to Old Castile, and bounded on the N. by Logroño, E. by Saragossa, S. by Guadalajara and W. by Segovia and Burgos. Pop. (1900), 150,462; area, 3983 sq. m. Soria is a bleak and lofty region, bounded on three sides by mountains. A range of sierras culminating in the peaks of Urbion (7389 ft.) and Cebollera (7139 ft.) on the north, and the great Sierra del Moncayo (7707 ft.) on the east, separate the valley of the Duero (Douro) from that of the Ebro, while on the south it is divided from the valley of the Tagus by a continuation of the Sierra Guadarrama. Almost the whole of the province belongs to the region watered by the Duero and its affluents. This river rises among the southern slopes of Urbion and traverses the province in a circuitous course, first to the south and then to the west. The other rivers are mostly affluents of the Duero, but a few of the tributaries of the Ebro have their sources within the limits of the province. The soil is not remarkable for fertility; a large proportion of the area being occupied with barren mountains, which are covered with snow for a great part of the year. There are, however, in some places extensive forests of pine, oak and beech; while in others there are large tracts of pasture land, on which numbers of cattle, sheep and swine are reared. Grain and vegetables are raised, but neither of very good quality nor in sufficient quantities to supply the wants of the population. The climate is cold and dry, and the scenery grand, but austere. Most of the people are employed in farming and rearing cattle; but the cutting and sawing of timber and the preparation of charcoal also occupy a considerable number. There is a great want of roads; and, although three railways traverse the province, commerce is consequently very limited. Fine wool was formerly produced; but the only important articles of trade at present are timber, salt, asphalt, leather and cheese, which are sent to Madrid and Aragon. Salt and asphalt are the only minerals worked, though others are known to exist. The capital, Soria, is described below. The only other town with more than 3500 inhabitants is El Burgo de Osma (3509), an episcopal see. Between 1887 and 1900 the population decreased by nearly 7000; its density in the last-named year was 37·7 per sq. m., or lower than that of any other Spanish province except Cuenca (37·6). The gradual depopulation of many districts is due to the stagnation of industry, and the attraction of emigrants to large towns outside the province.

SORIA, the capital of the Spanish province of Soria; on the right bank of the river Duero (Douro), 155 m. N.E. of Madrid by the Madrid-Alcuneza-Soria railway. Pop. (1900), 7151. Soria has a provincial institute, schools for teachers of both sexes, many primary schools, savings banks, two hospitals, barracks, a theatre and a bull-ring. The churches of Santo Domingo and San Nicolas, the cloisters of the convent of San Juan, and several other ecclesiastical buildings are fine specimens of Romanesque work of the 12th and 13th centuries. Near the Duero are the ruins of the old citadel, and in many places the remains of the 13th century walls of the city are yet standing. The more modern streets are clean and well paved. The bridge across the Duero is a massive structure which formerly had a tower in the centre. The population is chiefly agricultural; but there are also flour mills, tanneries, potteries, &c.; and some trade in timber, wool and fruit is carried on. The Iberian and Carthaginian city of Numantia, captured in 133 B.C. by the Romans, after a long and heroic resistance, was situated 3 m. N., on a hill overlooking the confluence of the small river Tera with the Duero.

SOROKI, a town of south Russia, in the government of Bessarabia, 81 m. N.N.W. of Kishinev, in a narrow ravine on the right bank of the Dnieper. Pop. (1900), 25,523, half of whom were Jews. It is an important river port for the export of corn, wool, fruit, wine and cattle. Formerly it was the old Genoese colony of Olchionia, and has still the ruins of a 13th-century Genoese castle. In the 15th century the Moldavians erected here a fort, which the Poles took in the 17th century. Peter the Great captured the place in 1711, but it was returned to the Turks, and was only definitely annexed to Russia in 1812. (M. H. S.)

SOROLLA Y BASTIDA, JOAQUIN (1863–), Spanish painter, was born in Valencia, and received his art education first in his native town and under F. Pradilla, and then in Italy and Paris. His first striking success he achieved with "Another Margaret," which was awarded a gold medal in Madrid and was bought for the St Louis Gallery. He soon rose to general fame and became the acknowledged head of the modern Spanish school of painting. His picture of the "Fishermen's Return" was much admired at the Paris Salon and was acquired by the state for the Luxembourg Museum. His exhibit at the Paris Universal Exposition of 1900 won him a medal of honour and his nomination as Knight of the Legion of Honour. A special exhibition of his works—figure subjects, landscapes and portraits—at the Georges Petit Gallery in Paris in 1906 eclipsed all his earlier successes and led to his appointment as Officer of the Legion of Honour. He is represented at the Berlin National Gallery, at the Venice and Madrid Museums, and in many private collections in Europe and America, especially in Buenos Aires. He painted portraits of King Alphonso and Queen Victoria Eugénie of Spain, and a magnificent portrait group of the family of Don Aureliano de Beruete. Three of his works were shown in London at the Spanish Exhibition, Guildhall, 1901.

SORREL, *Rumex Acetosa*, a member of the natural order Polygonaceae, a hardy perennial, native to Britain and found throughout the north temperate zone. The leaves are used in soups, salads and sauces. Sorrel grows freely in any good garden soil, and is increased by dividing the roots during the early part of spring. They should be planted in rows 15 to 18 in. apart. The leaves, when fully grown, are gathered singly. The common garden sorrel is much superior to the wild plant; but the Belleville, which is the kind generally cultivated near Paris, is still better, its leaves being larger and not so acid. The Blistered-leaved, which has large leaves with a blistered surface, has the advantage of being slow in running to seed. French Sorrel (*Rumex scutatus*) is a hardy perennial, distributed through Europe but not native in Britain, with densely-branched trailing stems. The leaves are roundish, heart-shaped and glaucous; they are more acid than those of the common sorrel.

SORRENTO (anc. *Surrentum*, *q.v.*), a city of Campania, Italy, in the province of Naples, 10 m. by electric tramway (along the highroad) S.W. from Castellammare di Stabia, and served also by steamer from Naples (16 m.). Pop. (1901), 6849 (town); 8832 (commune). It stands on cliffs about 160 ft. above sea-level on the north side of the peninsula that separates the Bay of Naples from the Bay of Salerno. Sorrento contains only a few ancient remains, and its present prosperity depends mainly on its reputation as a place of resort both in winter and in summer, its northerly aspect rendering it comparatively cool. Its climate is delightful and healthy, and it is situated amid picturesque coast scenery. The chief local industries are the inlaying of wood, silk and lace-making and straw-plaiting, and the growing of oranges and lemons. In ancient times the Surrentine wines had a great repute.

In 1558 the corsair Pialy attacked the town and carried off two thousand prisoners. It was at Sorrento that Bernardo Tasso wrote his *Amadigi*; and Torquato Tasso, to whom a marble statue has been erected in the Piazza, was born in the town in 1544.

SOSIGENES, Greek astronomer and mathematician, probably of Alexandria, flourished in the 1st century B.C. According to Pliny (*Nat. Hist.* xviii. 25), he was employed by Julius Caesar in the reform of the Roman calendar (46 B.C.), and wrote three treatises, which he conscientiously corrected. From another passage of Pliny (ii. 8) it is inferred that Sosigenes maintained the doctrine of the motion of Mercury round the sun, which is referred to by his contemporary Cicero, and was also held by the Egyptians.

The astronomer is to be distinguished from the Peripatetic philosopher of the same name, who lived at the end of the 2nd century A.D. He was the tutor of Alexander of Aphrodisias, the most famous of the commentators on Aristotle. He wrote a work on *Revolving Spheres*, from which some important extracts have been preserved in Simplicius's commentary on Aristotle's *De caelo* (the subject is fully discussed by T. H. Martin, "Sur deux Sosigène," in *Annales de la fac. des lettres de Bordeaux*, i., 1879).

SOSITHEUS (*c.* 280 B.C.), Greek tragic poet, of Alexandria Troas, a member of the Alexandrian "pleiad." He must have resided at some time in Athens, since Diogenes Laërtius tells us (vii. 5, 4) that he attacked the Stoic Cleanthes on the stage, and was hissed off by the audience. As Suïdas also calls him a Syracusan, it is conjectured that he belonged to the literary circle at the court of Hiero II. According to an epigram of Dioscorides in the Greek Anthology (*Anth. Pal.* vii. 707) he restored the satyric drama in its original form. A considerable fragment is extant of his pastoral play *Daphnis* or *Lityerses*, in which the Sicilian shepherd, in search of his love Pimplea, is brought into connexion with the Phrygian reaper, son of Midas, who slew all who unsuccessfully competed with him in reaping his corn. Heracles came to the aid of Daphnis and slew Lityerses.

See O. Crusius *s.v.* Lityerses in Roscher's *Lexikon der griechischen und römischen Mythologie*. The fragment of twenty-one lines in Nauck's *Tragicorum graecorum fragmenta* apparently contains the beginning of the drama. Two lines from the *Aëthlius* (probably the traditional first king of Elis, father of Endymion) are quoted by Stobaeus (*Flor.* li. 23).

SOTADES, Greek satirist, of Maronea in Thrace (or of Crete), chief representative of the writers of coarse satirical poems, called κίναιδοι,[1] composed in the Ionic dialect and in a metre named after him "sotadic." He lived in Alexandria during the reign of Ptolemy II. Philadelphus (285–247 B.C.). For a violent attack on the king, on the occasion of his marriage to his own sister Arsinoë, Sotades was imprisoned, but escaped to the island of Caunus, where he was afterwards captured by Patroclus, Ptolemy's admiral, shut up in a leaden chest, and thrown into the sea (Athenaeus xiv. p. 620; Plutarch, *De educatione puerorum*, 14).

Only a few genuine fragments of Sotades have been preserved (see J. G. Hermann, *Elementa doctrinae metricae*, 1816); those in Stobaeus are generally considered spurious. Ennius translated some poems of this kind, included in his book of satires, under the name of *Sota*.

SOTER, pope from about 167 to 174. He wrote to the Church of Corinth and sent it aid. His letter is mentioned in the reply given by Dionysius, bishop of Corinth, and Harnack thinks it can be identified with the second so-called epistle of Clement to the Corinthians.

SOTHEBY, WILLIAM (1757–1833), English author, was born in London on the 9th of November 1757. He was educated at Harrow, and subsequently procured a commission in a cavalry regiment. In 1780 he retired from the army on his marriage and devoted himself to literature, becoming a prominent figure in London literary society. His ample means enabled him to play the part of patron to many struggling authors, and his friends included Scott, Byron, Wordsworth, Coleridge, Southey, Hallam and Tom Moore. He himself soon acquired a considerable reputation as a translator, his verse translation of Virgil's *Georgics* (1800) being specially praised by contemporary critics, while in later life he published translations of the *Iliad* and *Odyssey*. He also wrote several historical tragedies for the stage, of which one was acted, and some poems. He died on the 30th of December 1833.

SOTHERN, EDWARD ASKEW (1826–1881), English actor, was born in Liverpool on the 1st of April 1826, the son of a merchant. He began acting as an amateur, and in 1849 drifted into a professional engagement with a dramatic company at St Heliers in Jersey, where he appeared as Claude Melnotte in Bulwer Lytton's *Lady of Lyons*. Between then and 1858 he played in various companies without particular success, in Birmingham and in America, where he went in 1852. On the 12th of May 1858 Tom Taylor's *Our American Cousin*, a play of no special merit, was brought out in New York, with Sothern in the small part of Lord Dundreary, a caricature of an English nobleman. He gradually worked up the humour of this part so that it became the central figure of the play. In 1861, when it was produced at the Haymarket Theatre, in London, he made such a hit that the piece ran for nearly five hundred nights: "Dundreary whiskers" became the fashion, and Dundreary this, that or the other made its appearance on every side. At various times Sothern revived the character, which retained its popularity in spite of all the extravagances to which he developed its amusing features; and his name will always be famous in connexion with this rôle. In T. W. Robertson's *David Garrick* (1864) he again had a great success, his acting in the title-part, which he created, being wonderfully effective. He won wide popularity also from his interpretation of Sam Slingsby in Oxenford's *Brother Sam* (1865). Sothern was a born comedian, and off the stage had a passion for practical joking that amounted almost to a mania. His house in Kensington was a resort for people of fashion, and he was as much a favourite in America as in the United Kingdom. He died in London on the 21st of January 1881.

Sothern had three sons, all actors, the second of them, EDWARD H. SOTHERN (b. 1859), being prominent on the American stage.

SOTHIC PERIOD, in ancient Egyptian chronology, the period in which the year of 365 days circled in succession through all the seasons. The tropical year, determined as it was in Egypt by the heliacal rising of Sirius (Sothis), was almost exactly the Julian year of precisely $365\frac{1}{4}$ days (differing from the true solar year, which was 11 minutes less than this). The sothic period was thus 1461 years.

See EGYPT, *Ancient*, § F. "Chronology."

SOTO, FERDINANDO [FERNANDO, or HERNANDO] **DE** (1496?–1542), Spanish captain and explorer, often, though wrongly, called the discoverer of the Mississippi (first sighted by Alonzo de Pineda in 1519), was born at Jeréz de los Caballeros, in Estremadura, of an impoverished family of good position, and was indebted to the favour of Pedrarias d'Avila for the means of pursuing his studies at the university. In 1519 he accompanied d'Avila on his second expedition to Darien. In 1528 he explored the coast of Guatemala and Yucatan, and in 1532 he led 300 volunteers to reinforce Pizarro in Peru. He played a prominent part in the conquest of the Incas' kingdom (helping to seize and guard the person of Atahualpa, discovering a pass through the mountains to Cuzco, &c.), and returned to Spain with a fortune of 180,000 ducats, which enabled him to marry the daughter of his old patron d'Avila, and to maintain the state of a nobleman. Excited by the reports of Alvaro Nuñez (Cabeza de Vaca) and others as to the wealth of Florida (a term then commonly used in a much wider extension than subsequently), he sold great part of his property, gathered a force of 620 foot and 123 horse, armed four ships, and obtained from Charles V. a commission as "adelantado of the Lands of Florida" and governor of Cuba. Sailing from San Lucar in April 1538, he first went to Havana, his advanced base of operations; starting thence on the 12th of May 1539 he landed in the same month in Espiritu Santo Bay, on the west coast of the present state of Florida. For nearly four years he led his men in fruitless search of gold hither and thither over the south-east of the North

[1] The word is also used of the dancers in indecent ballets, to which such poems were probably written as an accompaniment. In Greek and Latin authors κίναιδος (*cinaedus*) generally means "catamite."

American continent. His exact route is often doubtful; but it seems to have passed north into Georgia as far as 35′ N., then south to the neighbourhood of Mobile, and finally north-west towards the Mississippi. This river was reached early in 1541, and the following winter was spent on the Ouachita, in modern Arkansas and Louisiana, west of the Mississippi. As they were returning in 1542 along the Mississippi, De Soto died (either in May or June; the 25th of June is perhaps the true date), and his body was sunk in its waters. Failing in an attempt to push westwards again, De Soto's men, under Luis Moscoso de Alvarado, descended the Mississippi to the sea in nineteen days from a point close to the junction of the Arkansas with the great river, and thence coasted along the Gulf of Mexico to Panuco.

Of this unfortunate expedition three very different narratives are extant, of seemingly independent origin. The first was published in 1557 at Evora, and professes to be the work of a Portuguese gentleman of Elvas, who had accompanied the expedition: *Relaçam verdadeira dos trabalhos q̃ ho gouernador dõ Fernõdo d'Souto & certos fidalgos portugueses passarom no d'scobrimẽto da Provincia da Florida. Agora nouamẽte feita per hu fidalgo Deluas.* An English translation was published by Hakluyt in 1609 (reprinted from the 1611 edition by the Hakluyt Society [London, 1851]), and another by an anonymous translator in 1686, the latter being based on a French version by Citri de la Guette (Paris, 1685). The second narrative is the famous history of Florida by the Inca, Garcilasso de la Vega, who obtained his information from a Spanish cavalier engaged in the enterprise; it was completed in 1591, first appeared at Lisbon in 1605 under the title of *La Florida del Ynca*, and has since passed through many editions in various languages. The third is a report presented to Charles V. of Spain in his Council of the Indies in 1544, by Luis Hernandez de Biedma, who had accompanied De Soto as His Majesty's factor. It is to be found in Ternaux-Compans' "Recueil de pièces sur la Floride" in the *Historical Collections of Louisiana* (Philadelphia, 1850) and in W. B. Rye's reprint for the Hakluyt Society of Hakluyt's translation of the Portuguese narrative (*The Discovery and Conquest of Terra Florida*, London, 1851).

M'Culloch, *Researches . . . concerning the aboriginal history of America* (Baltimore, 1829); Albert Gallatin, "Synopsis of the Indian Tribes," in *Archaeologia americana*, vol. ii. (Cambridge, Mass., 1836); E. G. Bourne (ed.), *Narratives of the Career of Hernando de Soto in the Conquest of Florida* (2 v., New York, 1904); J. W. Monette, *History of the Discovery and Settlement of the Valley of the Mississippi* (New York, 1846, 2 vols.).

SOU (O. Fr. *sol*, Lat, *solidus*, sc. *nummus*), the name of the bronze 5-centime French coin, corresponding to the English "halfpenny." It is still colloquially used in France in reckoning, and the franc, 2 and 5-franc pieces are known as *pièce de vingt*, *quarante* and *cent sous* respectively. The *solidus* was originally a gold coin, first struck *c.* A.D. 312 by Constantine to take the place of the *aureus*. In the Eastern Empire this gold coin was the standard down to 1453, and, as the "bezant," circulated from Portugal to the Indies. In the West after Pippin gold coinage ceased and the *solidus* in silver became the standard, one pound of silver making 22 *sols* (*solidi*) and 264 *deniers* (*denarii*). Under Charlemagne one pound of silver = 20 sols = 240 deniers. The *livre* (*libra*), the *sol* and the *denier* formed the universal money of account throughout France until the Revolution; and they have left their mark on the English money symbols *£ s. d.*, for pounds, shillings and pence.

SOUBISE, BENJAMIN DE ROHAN, Duc de (? 1589–1642), Huguenot leader, younger brother of Henri de Rohan, inherited his title through his mother Catherine de Parthenay. He served his apprenticeship as a soldier under Prince Maurice of Orange-Nassau in the Low Countries. In the religious wars from 1621 onwards his elder brother chiefly commanded on land and in the south, Soubise in the west and along the sea-coast. His exploits in the conflict have been sympathetically related by his brother, who, if he was not quite an impartial witness, was one of the best military critics of the time. Soubise's chief exploit was a singularly bold and well-conducted attack (in 1625) on the Royalist fleet in the river Blavet (which included the cutting of a boom in the face of superior numbers) and the occupation of Oléron. He commanded at Rochelle during the famous siege, and (if we may believe his brother) the failure of the defence and of the English attack on Rhé was mainly due to the alternate obstinacy of the townsfolk and the English commanders in refusing to listen to Soubise's advice. When surrender became inevitable he fled to England, which he had previously visited in quest of succour. He died in 1642 in London. The Soubise title afterwards served as the chief second designation (not for heirs apparent, but for the chief collateral branch for the time being) of the house of Rohan-Chabot.

The name Soubise appears again in the military history of France in the person of Charles de Rohan, Prince de Soubise (1715–1787), peer and marshal of France, the grandson of the princesse de Soubise, who is known to history as one of the mistresses of Louis XIV. He accompanied Louis XV. in the campaign of 1744–48 and attained high military rank, which he owed more to his courtiership than to his generalship. Soon after the beginning of the Seven Years' War, through the influence of Mme de Pompadour, he was put in command of a corps of 24,000 men, and in November 1757 he sustained the crushing defeat of Rossbach. He was more fortunate, however, in his later military career, and continued in the service until the general peace of 1763, after which he lived the life of an ordinary courtier and man of fashion in Paris, dying on the 4th of July 1787.

SOUHAM, JOSEPH, Count (1760–1837), French soldier, was born at Lubersac on the 30th of April 1760, and served in the French army as a private from 1782 to 1790. In 1792, having shown himself active in the cause of the Revolution, he was elected commandant of a volunteer battalion, and by 1793 he had risen to the rank of general of division. He served with credit under Pichegru in Holland (1795), but in 1799 fell into disgrace on suspicion of being concerned in Royalist intrigues. He was reinstated in 1800 and served under Moreau in the Danube campaign of that year. During the Consulate he appears to have been involved in conspiracies, and along with his old commanders Moreau and Pichegru was disgraced for alleged participation in that of Georges Cadoudal. He regained his rank, however, in 1809, took a notable part in Gouvion St Cyr's operations in Catalonia, and won the title of count by his conduct at the action of Vich, in which he was wounded. In 1812 Marshal Masséna, in declining the command of Marmont's army which had just been defeated at Salamanca, recommended Souham for the post. The latter was thus pitted against Wellington, and by his skilful manœuvres drove the English general back from Burgos and regained the ground lost at Salamanca. In 1813 he distinguished himself again at Lützen and at Leipzig (when he was wounded). At the fall of the First Empire he deserted the emperor, and having suffered for the Royalist cause was well received by Louis XVIII., who gave him high commands. These Souham lost at the return of Napoleon and regained after the Second Restoration. He retired in 1832, and died on the 28th of April 1837.

SOULARY, JOSEPHIN [Joseph Marie] (1815–1891), French poet, son of a Lyons merchant of Genoese origin (Solari), was born on the 23rd of February 1815. He entered a line regiment when he was sixteen, serving for five years. He was chef de bureau in the prefecture of the Rhône from 1845 to 1867, and in 1868 he became librarian to the *Palais des arts* in his native town. He died at Lyons on the 28th of March 1891. His works include *À travers champs* (1837); *Les Cinq cordes du luth* (1838); *Les Ephémères* (two series, 1846 and 1857); *Sonnets humoristiques* (1862); *Les Figulines* (1862); *Pendant l'invasion* (1871); *Les Rimes ironiques* (1877); *Jeux divins* (1882), and two comedies. His *Œuvres poétiques* were collected in three volumes (1872–1883). His *Sonnets humoristiques* attracted great attention, and charmed their readers by the mixture of gaiety and tragedy. His mastery over the technical difficulties of his art, especially in the sonnet, won him the title of the "Benvenuto of rhyme."

See also Paul Mariéton, *Soulary et la Pléiade lyonnaise* (1884).

SOULT, NICOLAS JEAN DE DIEU, Duke of Dalmatia (1769–1851), marshal of France, was born at Saint-Amans-la-Bastide (now in department of the Tarn) on the 29th of March 1769, and was the son of a country notary at that place. He was fairly well educated, and intended for the bar, but his father's death when he was still a boy made it necessary for him to seek his fortune, and he enlisted as a private in the French infantry in 1785. His superior education ensured his promotion to the rank of sergeant after six years' service, and in July 1791 he became instructor to the first battalion of volunteers of the Bas-Rhin. He served with his battalion in 1792. By 1794 he was adjutant-general (with the rank of *chef de brigade*). After the battle of Fleurus, in which he greatly distinguished himself for coolness, he was promoted general of brigade by the representatives on mission. For the next five years he was constantly employed in Germany under Jourdan, Moreau, Kléber and Lefebvre, and in 1799 he was promoted general of division and ordered to proceed to Switzerland. It was at this time that he laid the foundations of his military fame, and he particularly distinguished himself in Masséna's great Swiss campaign, and especially at the battle of Zürich. He accompanied Masséna to Genoa, and acted as his principal lieutenant throughout the protracted siege of that city, during which he operated with a detached force without the walls, and after many successful actions he was wounded and taken prisoner at Monte Cretto on the 13th of April 1800. The victory of Marengo restoring his freedom, he received the command of the southern part of the kingdom of Naples, and in 1802 he was appointed one of the four generals commanding the consular guard. Though he was one of those generals who had served under Moreau, and who therefore, as a rule, disliked and despised Napoleon, Soult had the wisdom to show his devotion to the ruling power; in consequence he was in August 1803 appointed to the command-in-chief of the camp of Boulogne, and in May 1804 he was made one of the first marshals of France. He commanded a corps in the advance on Ulm, and at Austerlitz (*q.v.*) he led the decisive attack on the allied centre. He played a great part in all the famous battles of the *Grande Armée*, except the battle of Friedland (on the day of which he forced his way into Königsberg), and after the conclusion of the peace of Tilsit he returned to France and was created (1808) duke of Dalmatia. In the following year he was appointed to the command of the II. corps of the army with which Napoleon intended to conquer Spain, and after winning the battle of Gamonal he was detailed by the emperor to pursue Sir John Moore, whom he only caught up at Corunna.

For the next four years Soult remained in Spain, and his military history is that of the Peninsular War (*q.v.*). In 1809, after his defeat by Sir John Moore, he invaded Portugal and took Oporto, but, busying himself with the political settlement of his conquests in the French interests and, as he hoped, for his own ultimate benefit as a possible candidate for the throne, he neglected to advance upon Lisbon, and was eventually dislodged from Oporto by Sir Arthur Wellesley, making a painful and almost disastrous retreat over the mountains. After the battle of Talavera he was made chief of staff of the French troops in Spain with extended powers, and on the 19th of November 1809 won the great victory of Ocaña. In 1810 he invaded Andalusia, which he speedily reduced, with the exception of Cadiz. In 1811 he marched north into Estremadura, and took Badajoz, and when the Anglo-Portuguese army laid siege to it he marched to its rescue, and fought the famous battle of Albuera (May 16). In 1812, however, he was obliged, after Wellington's great victory of Salamanca, to evacuate Andalusia, and was soon after recalled from Spain at the request of Joseph Bonaparte, with whom, as with the other marshals, he had always disagreed. In March 1813 he assumed the command of the IV. corps of the *Grande Armée* and commanded the centre at Lützen and Bautzen, but he was soon sent, with unlimited powers, to the south of France to repair the damage done by the great defeat of Vittoria. His campaign there is the finest proof of his genius as a general, although he was repeatedly defeated by the English under Wellington, for his soldiers were but raw conscripts, while those of Wellington were the veterans of many campaigns.

Such was the military career of Marshal Soult. His political career was by no means so creditable, and it has been said of him that he had character only in front of the enemy. After the first abdication of Napoleon he declared himself a Royalist, received the order of St Louis, and acted as minister for war from the 3rd of December 1814 to the 11th of March 1815. When Napoleon returned from Elba Soult at once declared himself a Bonapartist, was made a peer of France and acted as major-general (chief of staff) to the emperor in the campaign of Waterloo, in which rôle he distinguished himself far less than he had done as commander of an over-matched army. At the Second Restoration he was exiled, but not for long, for in 1819 he was recalled and in 1820 again made a marshal of France. He once more tried to show himself a fervent Royalist and was made a peer in 1827. After the revolution of 1830 he made out that he was a partisan of Louis Philippe, who welcomed his adhesion and revived for him the title of marshal-general. He served as minister for war from 1830 to 1834, as ambassador extraordinary to London for the coronation of Queen Victoria in 1838, and again as minister for war from 1840 to 1844. In 1848, when Louis Philippe was overthrown, Soult again declared himself a republican. He died at his castle of Soultberg, near his birthplace, on the 26th of November 1851. Soult himself wrote but little. He published a memoir justifying his adhesion to Napoleon during the Hundred Days, and his notes and journals were arranged by his son Napoleon Hector (1801–1857), who published the first part (*Mémoires du maréchal-général Soult*) in 1854. Le Noble's *Mémoires sur les opérations des Français en Galicie* are supposed to have been written from Soult papers.

See A. Sallé, *Vie politique du maréchal Soult* (Paris, 1834); A. de Grozelier, *Le Maréchal Soult* (Castres, 1851); A. Combes, *Histoire anecdotique du maréchal Soult* (Castres, 1869).

SOUMET, ALEXANDRE (1788–1845), French poet, was born on the 8th of February 1788 at Castelnaudary, department of Aude. His father wished him to enter the army, but an early-developed love of poetry turned the boy's ambition in other directions. He was an admirer of Klopstock and Schiller, then little known in France, and reproached Mme de Staël with lack of enthusiasm for her subject in *De l'Allemagne*. Soumet came to Paris in 1810, and some poems in honour of Napoleon secured his nomination as auditor of the Conseil d'État. His well-known elegy *La Pauvre fille* appeared in 1814, and two successful tragedies produced in 1822, *Clytemnestre* and *Saül*, secured his admission to the Academy in 1824. *Jeanne d'Arc* (1825) aroused great enthusiasm, and was the best of his plays. Among his other pieces *Élisabeth de France* (1828), a weak imitation of Schiller's *Don Carlos*, may be noted, but Soumet's real bent was towards epic poetry. His most considerable work is a poem inspired by Klopstock, *La Divine épopée*, which describes the descent of Christ into Hades. Under Louis XVIII. he became librarian of Saint-Cloud, and subsequently was transferred to Rambouillet and to Compiègne. He died on the 30th of March 1845, leaving an unfinished epic on Jeanne d'Arc. His daughter Gabrielle (Mme Beauvain d'Altenheim) had collaborated with him in some of his later works.

SOUND,[1] subjectively the sense impression of the organ of

[1] "Sound" is an interesting example of the numerous homonymous words in the English language. In the sense in which it is treated in this article it appears in Middle English as *soun*, and comes through Fr. *son* from Lat. *sonus*; the *d* is a mere addition, as in the nautical term "bound" (outward, homeward bound) for the earlier "boun," to make ready, prepare. In the adjectival meaning, healthy, perfect, complete, chiefly used of a deep undisturbed sleep, or of a well-based argument or doctrine, or of a person well trained in his profession, the word is in O. Eng. *sund*, and appears also in Ger. *gesund*, Du. *gezond*. It is probably cognate with the Lat. *sanus*, healthy, whence the Eng. sane, insanity, sanitation, &c. Lastly, there is a group of words which etymologists are inclined to treat as being all forms of the word which in O. Eng. is *sund*, meaning "swimming." These words are for (1) the swim-bladder of a fish; (2) a narrow stretch of water between an inland sea and the ocean, or between an island and the mainland, &c., cf. SOUND, THE, below; (3) to test or measure the depth of anything, particularly the depth of water in lakes or seas (see SOUNDING, below). As a substantive the term is used of a surgical instrument for the exploration of a wound, cavity, &c., a probe. In these senses the word has frequently been referred to Lat. *sub unda*, under the water; and Fr. *sombre*, gloomy, possibly from *sub umbra*, beneath the shade, is given as a parallel.

hearing, and objectively the vibratory motion which produces the sensation of sound. The physiological and psychical aspects of sound are treated in the article HEARING. In this article, which covers the science of Acoustics, we shall consider only the physical aspect of sound, that is, the physical phenomena outside ourselves which excite our sense of hearing. We shall discuss the disturbance which is propagated from the source to the ear, and which there produces sound, and the modes in which various sources vibrate and give rise to the disturbance.

Sound is due to Vibrations.—We may easily satisfy ourselves that, in every instance in which the sensation of sound is excited, the body whence the sound proceeds must have been thrown, by a blow or other means, into a state of agitation or tremor, implying the existence of a vibratory motion, or motion to and fro, of the particles of which it consists.

Thus, if a common glass-jar be struck so as to yield an audible sound, the existence of a motion of this kind may be felt by the finger lightly applied to the edge of the glass; and, on increasing the pressure so as to destroy this motion the sound forthwith ceases. Small pieces of cork put in the jar will be found to dance about during the continuance of the sound; water or spirits of wine poured into the glass will, under the same circumstances, exhibit a ruffled surface. The experiment is usually performed, in a more striking manner, with a bell-jar and a number of small light wooden balls suspended by silk strings to a fixed frame above the jar, so as to be just in contact with the widest part of the glass. On drawing a violin bow across the edge, the pendulums are thrown off to a considerable distance, and falling back are again repelled, and so on.

It is also in many cases possible to follow with the eye the motions of the particles of the sounding body, as, for instance, in the case of a violin string or any string fixed at both ends, when the string will appear through the persistence of visual sensation to occupy at once all the positions which it successively assumes during its vibratory motion.

Sound takes Time to Travel.—If we watch a man breaking stones by the roadside some distance away, we can see the hammer fall before we hear the blow. We see the steam issuing from the whistle of a distant engine long before we hear the sound. We see lightning before we hear the thunder which spreads out from the flash, and the more distant the flash the longer the interval between the two. The well-known rule of a mile for every five seconds between flash and peal gives a fair estimate of the distance of the lightning.

Sound needs a Material Medium to Travel Through.—In order that the ear may be affected by a sounding body there must be continuous matter reaching all the way from the body to the ear. This can be shown by suspending an electric bell in the receiver of an air-pump, the wires conveying the current passing through an air-tight cork closing the hole at the top of the receiver. These wires form a material channel from the bell to the outside air, but if they are fine the sound which they carry is hardly appreciable. If while the air within the receiver is at atmospheric pressure the bell is set ringing continuously, the sound is very audible. But as the air is withdrawn by the pump the sound decreases, and when the exhaustion is high the bell is almost inaudible.

Usually air is the medium through which sound travels, but it can travel through solids or liquids. Thus in the air-pump experiment, before exhaustion it travels through the glass of the receiver and the base plate. We may easily realise its transmission through a solid by putting the ear against a table and scratching the wood at some distance, and through a liquid by keeping both ears under water in a bath and tapping the side of the bath.

Sound is a Disturbance of the Wave Kind.—As sound arises in general from vibrating bodies, as it takes time to travel, and as the medium which carries it does not on the whole travel forward, but subsides into its original position when the sound has passed, we are forced to conclude that the disturbance is of the wave kind, We can at once gather some idea of the nature of sound waves in air by considering how they are produced by a bell.

Let AB (fig. 1) be a small portion of a bell which vibrates to and fro from CD to EF and back. As AB moves from CD to EF it pushes forward the layer of air in contact with it. That layer presses against and pushes forward the next layer and so on. Thus a push or a compression of the air is transmitted onwards in the direction OX. As AB returns from EF towards CD the layer of air next to it follows it as if it were pulled back by AB. Really, of course, it is pressed into the space made for it by the rest of the air, and flowing into this space it is extended. It makes room for the next layer of air to move back and to be extended and so on, and an extension of the air is transmitted onwards following the compression which has already gone out. As AB again moves from CD towards EF another compression or push is sent out, as it returns from EF towards CD another extension or pull, and so on. Thus waves are propagated along OX, each wave consisting of one push and one pull, one wave emanating from each complete vibration to and fro of the source AB.

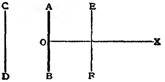


FIG. 1.

Crova's Disk.—We may obtain an excellent representation of the motion of the layers of air in a train of sound waves by means of a device due to Crova and known as "Crova's disk." A small circle, say 2 or 3 mm. radius, is drawn on a card as in fig. 2, and round this circle equidistant points, say 8 or 12, are

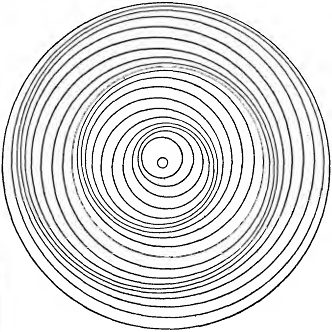

FIG. 2.

taken. From these points as centres, circles are drawn in succession, each with radius greater than the last by a fixed amount, say 4 or 5 mm. In the figure the radius of the inner circle is 3 mm. and the radii of the circles drawn round it are 12, 16, 20, &c. If the figure thus drawn is spun round its centre in the right direction in its own plane waves appear to travel out from the centre along any radius. If a second card with a narrow slit in it is held in front of the first, the slit running from the centre outwards, the wave motion is still more evident. If the figure be photographed as a lantern slide which is mounted so as to turn round, the wave motion is excellently shown on the screen, the compressions and extensions being represented by the crowding in and opening out of the lines.

Another illustration is afforded by a long spiral of wire with coils, say 2 in. in diameter and ½ in. apart. It may be hung up by threads so as to lie horizontally. If one end is sharply pressed in, a compression can be seen running along the spring.

The Disturbance in Sound Waves is Longitudinal.—The motion of a particle of air is, as represented in these illustrations, to and fro in the direction of propagation, *i.e.* the disturbance is "longitudinal." There is no "transverse" disturbance, that is, there is in air no motion across the line of propagation, for such motion could only be propagated from one layer to the next by the "viscous" resistance to relative motion, and would die away at a very short distance from the source. But transverse disturbances may be propagated as waves in solids. For instance, if a rope is fixed at one end and held in the hand at the other end, a transverse jerk by the hand will travel as a transverse wave along the rope. In liquids sound waves are longitudinal as they are in air. But the waves on the surface of a liquid, which are not of the sound kind, are both longitudinal and transverse, the compound nature being easily seen in watching the motion of a floating particle.

Displacement Diagram.—We can represent waves of longitudinal displacement by a curve, and this enables us to draw very important conclusions in a very simple way. Let a train of waves be passing from left to right in the direction ABCD (fig. 3). At every point

FIG. 3.

let a line be drawn perpendicular to AD and proportional to the displacement of the particle which was at the point before the disturbance began. Thus let the particle which was at L be at *l*, to the right or forwards, at a given instant. Draw LP upward and some convenient multiple of L*l*. Let the particle which was at M originally be at *m* at the given instant, being displaced to the left or backwards. Draw MQ downwards, the same multiple of M*m*. Let N be displaced forward to *n*. Draw NR the same multiple of N*n* and upwards. If this is done for every point we obtain a continuous curve APBQCRD, which represents the displacement at every point at the given instant, though by a length at right angles to the actual displacement and on an arbitrary scale. At the points ABCD there is no displacement, and the line AD through these points is called the *axis*. Forward displacement is represented by height above the axis, backward displacement by depth below it. In ordinary sound waves the displacement is very minute, perhaps of the order 10^{-5} cm., so that we multiply it perhaps by 100,000 in forming the displacement curve.

Wave Length and Frequency.—If the waves are continuous and each of the same shape they form a "train," and the displacement curve repeats itself. The shortest distance in which this repetition occurs is called the *wave-length*. It is usually denoted by λ. In fig. 3, $AC=\lambda$. If the source makes n vibrations in one second it is said to have "frequency" n. It sends out n waves in each second. If each wave travels out from the source with velocity U the n waves emitted in one second must occupy a length U and therefore $U=n\lambda$.

Distribution of Compression and Extension in a Wave.—Let fig. 4 be the displacement diagram of a wave travelling from left to right.

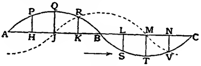

FIG. 4.

At A the air occupies its original position, while at H it is displaced towards the right or away from A since HP is above the axis. Between A and H, then, and about H, it is extended. At J the displacement is forward, but since the curve at Q is parallel to the axis the displacement is approximately the same for all the points close to J, and the air is neither extended nor compressed, but merely displaced bodily a distance represented by JQ. At B there is no displacement, but at K there is displacement towards B represented by KR, *i.e.* there is compression. At L there is also displacement towards B and again compression. At M, as at J, there is neither extension nor compression. At N the displacement is away from C and there is extension. The dotted curve represents the distribution of compression by height above the axis, and of extension by depth below it. Or we may take it as representing the pressure—excess over the normal pressure in compression, defect from it in extension.

The figure shows that when the curve of displacement slopes down in the direction of propagation there is compression, and the pressure is above the normal, and that when it slopes up there is extension, and the pressure is below the normal.

Distribution of Velocity in a Wave.—If a wave travels on without alteration the travelling may be represented by pushing on the displacement curve. Let the wave AQBTC (fig. 5) travel to A'QB'TC' in a very short time. In that short time the displacement at H decreases from HP to HP' or by PP'. The motion of the particle is therefore backwards towards A. At J the displacement remains the same, or the particle is not moving. At K it increases by RR' forwards, or the motion is forwards towards B. At L the displacement backward decreases, or the motion is forward

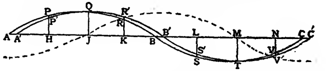

FIG. 5.

At M, as at J, there is no change, and at N it is easily seen that the motion is backward. The distribution of velocity then is represented by the dotted curve and is forward when the curve is above the axis and backward when it is below.

Comparing figs. 4 and 5 it is seen that the velocity is forward in compression and backward in extension.

The Relations between Displacement, Compression and Velocity.—The relations shown by figs. 4 and 5 in a general manner may easily be put into exact form. Let OX (fig. 6) be the direction

FIG. 6.

of travel, and let x be the distance of any point M from a fixed point O. Let $ON=x+dx$. Let $MP=y$ represent the forward displacement of the particle originally at M, and $NQ=y+dy$ that of the particle originally at N. The layer of air originally of thickness dx now has thickness $dx+dy$, since N is displaced forwards dy more than M. The volume dx, then, has increased to $dx+dy$ or volume 1 has increased to $1+dy/dx$ and the increase of volume 1 is dy/dx.

Let E be the bulk modulus of elasticity, defined as increase of pressure $\div$ decrease of volume per unit volume where the pressure increase is so small that this ratio is constant, ω the small increase of pressure, and $-(dy/dx)$ the volume *decrease*, then

$$E=\omega/(-dy/dx) \text{ or } \omega/E=-dy/dx \tag{1}$$

This gives the relation between pressure excess and displacement.

To find the relation of the velocity to displacement and pressure we shall express the fact that the wave travels on carrying all its conditions with it, so that the displacement now at M will arrive at N while the wave travels over MN. Let U be the velocity of the wave and let u be the velocity of the particle originally at N. Let $MN=dx=Udt$. In the time dt which the wave takes to travel over MN the particle displacement at N changes by QR, and $QR=-udt$, so that $QR/MN=-u/U$. But $QR/MN=dy/dx$. Then

$$u/U=-dy/dx \tag{2}$$

This gives the velocity of any particle in terms of the displacement. Equating (1) and (2)

$$u/U=\omega/E \tag{3}$$

which gives the particle velocity in terms of the pressure excess.

Generally, if any condition ϕ in the wave is carried forward unchanged with velocity U, the change of ϕ at a given point in time dt is equal to the change of ϕ as we go *back* along the curve a distance $dx=Udt$ at the beginning of dt.

Then $$\frac{d\phi}{dx}=-\frac{1}{U}\frac{d\phi}{dt}.$$

The Characteristics of Sound Waves Corresponding to Loudness, Pitch and Quality.—Sounds differ from each other only in the three respects of loudness, pitch and quality.

The *loudness* of the sound brought by a train of waves of given wave-length depends on the extent of the to and fro excursion of the air particles. This is obvious if we consider that the greater the vibration of the source the greater is the excursion of the air in the issuing waves, and the louder is the sound heard. Half the total excursion is called the amplitude. Thus in fig. 4 QJ is the amplitude. Methods of measuring the amplitude in sound waves in air have been devised and will be described later. We may say here that the energy or the intensity of the sound of given wave-length is proportional to the square of the amplitude.

The *pitch* of a sound, the note which we assign to it, depends on the number of waves received by the ear per second. This is generally equal to the number of waves issuing from the source per second, and therefore equal to its frequency of vibration. Experiments, which will be described most conveniently when we discuss methods of determining the frequencies of sources, prove conclusively that for a given note the frequency is the same whatever the source of that note, and that the ratio of the frequencies of two notes forming a given musical interval is the same in whatever part of the musical range the two notes are situated. Here it is sufficient to say that the frequencies of a note, its major third, its fifth and its octave, are in the ratios of 4 : 5 : 6 : 8.

The *quality* or *timbre* of sound, *i.e.* that which differentiates a note sounded on one instrument from the same note on another instrument, depends neither on amplitude nor on frequency or wave-length. We can only conclude that it depends on wave form, a conclusion fully borne out by investigation. The displacement curve of the waves from a tuning-fork on its resonance box, or from the human voice sounding *oo*, are nearly smooth and symmetrical, as in fig. 7*a*. That for the air waves from a violin are probably nearly as in fig. 7*b*.

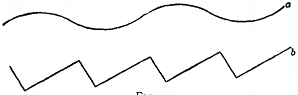

FIG. 7.

Calculation of the Velocity of Sound Waves in Air.—The velocity with which waves of longitudinal disturbance travel in air or in any other fluid can be calculated from the resistance to compression and extension and the density of the fluid. It is convenient to give this calculation before proceeding to describe the experimental determination of the velocity in air, in other gases and in water, since the calculation serves to some extent as a guide in conducting and interpreting the observations.

The waves from a source surrounded by a uniform medium at rest spread out as spheres with the source as centre. If we take one of these spheres a distance from the source very great as compared with a single wave-length, and draw a radius to a point on the sphere, then for some little way round that point the sphere may be regarded as a plane perpendicular to the radius or the line of propagation. Every particle in the plane will have the same displacement and the same velocity, and these will be perpendicular to the plane and parallel to the line of propagation. The waves for some little distance on each side of the plane will be practically of the same size. In fact, we may neglect the divergence, and may regard them as "plane waves."

We shall investigate the velocity of such plane waves by a method which is only a slight modification of a method given by W. J. M. Rankine (*Phil. Trans.*, 1870, p. 277).

Whatever the form of a wave, we could always force it to travel on with that form unchanged, and with any velocity we chose, if we could apply any "external" force we liked to each particle, in addition to the "internal" force called into play by the compressions or extensions. For instance, if we have a wave with displacement curve of form ABC (fig. 8), and we require it to travel

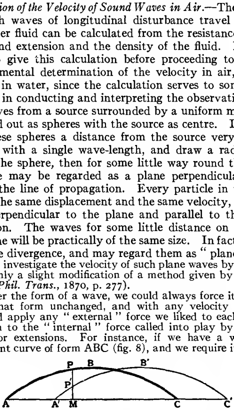

FIG. 8.

on in time dt to A'B'C', where $AA' = Udt$, the displacement of the particle originally at M must change from PM to P'M or by PP'. This change can always be effected if we can apply whatever force may be needed to produce it.

We shall investigate the external force needed to make a train of plane waves travel on unchanged in form with velocity U.

We shall regard the external force as applied in the form of a pressure X per square centimetre parallel to the line of propagation and varied from point to point as required in order to make the disturbance travel on unchanged in form with the specified velocity U. In addition there will be the internal force due to the change in volume, and consequent change in pressure, from point to point.

Suppose that the whole of the medium is moved *backwards* in space along the line of propagation so that the undisturbed portions travel with the velocity U. The disturbance, or the train of waves, is then fixed in space, though fresh matter continually enters the disturbed region at one end, undergoes the disturbance, and then leaves it at the other end.

Let A (fig. 9) be a point fixed in space in the disturbed region, B a fixed point where the medium is not yet disturbed, the medium

FIG. 9.

moving through A and B from right to left. Since the condition of the medium between A and B remains constant, even though the matter is continually changing, the momentum possessed by the matter between A and B is constant. Therefore the momentum entering through a square centimetre at B per second is equal to the momentum leaving through a square centimetre at A. Now the transfer of momentum across a surface occurs in two ways, firstly by the carriage of moving matter through the surface, and secondly by the force acting between the matter on one side of the surface and the matter on the other side. U cubic centimetres move in per second at B, and if the density is ρ_0 the mass moving in through a square centimetre is $\rho_0 U$. But it has velocity U, and therefore momentum $\rho_0 U^2$ is carried in. In addition there is a pressure between the layers of the medium, and if this pressure in the undisturbed parts of the medium is P, momentum P per second is being transferred from right to left across each square centimetre. Hence the matter moving in is receiving on this account P per second from the matter to the right of it. The total momentum moving in at B is therefore $P + \rho_0 U^2$. Now consider the momentum leaving at A. If the velocity of a particle at A relative to the undisturbed parts is u from left to right, the velocity of the matter moving out at A is $U - u$, and the momentum carried out by the moving matter is $\rho(U-u)^2$. But the matter to the right of A is also receiving momentum from the matter to the left of it at the rate indicated by the force across A. Let the excess of pressure due to change of volume be $\hat{\omega}$, so that the total "internal" pressure is $P + \hat{\omega}$. There is also the "external" applied pressure X, and the total momentum flowing out per second is

$$X + P + \hat{\omega} + \rho(U-u)^2.$$

Equating this to the momentum entering at B and subtracting P from each

$$X + \hat{\omega} + \rho(U-u)^2 = \rho_0 U^2. \qquad (4)$$

If y is the displacement at A, and if E is the elasticity, substituting for $\hat{\omega}$ and u from (2) and (3) we get

$$X - E\frac{dy}{dx} + \rho U^2\left(1 + \frac{dy}{dx}\right)^2 = \rho_0 U^2.$$

But since the volume dx with density ρ_0 has become volume $dx + dy$ with density ρ

$$\rho\left(1 + \frac{dy}{dx}\right) = \rho_0.$$

Then
$$X - E\frac{dy}{dx} + \rho_0 U^2\left(1 + \frac{dy}{dx}\right) = \rho_0 U^2,$$

or
$$X = (E - \rho_0 U^2)\,dy/dx. \qquad (5)$$

If then we apply a pressure X given by (5) at every point, and move the medium with any uniform velocity U, the disturbance remains fixed in space. Or if we now keep the undisturbed parts of the medium fixed, the disturbance travels on with velocity U if we apply the pressure X at every point of the disturbance.

If the velocity U is so chosen that $E - \rho_0 U^2 = 0$, then $X = 0$, or the wave travels on through the action of the internal forces only, unchanged in form and with velocity

$$U = \surd(E/\rho). \qquad (6)$$

The pressure X is introduced in order to show that a wave can be propagated unchanged in form. If we omitted it we should have to assume this, and equation (6) would give us the velocity of propagation if the assumption were justified. But a priori we are hardly justified in assuming that waves can be propagated at all, and certainly not justified in assuming that they go on unchanged by the action of the internal forces alone. If, however, we put on external forces of the required type X it is obvious that any wave can be propagated with any velocity, and our investigation shows that when U has the value in (6) then and only then X is zero everywhere, and the wave will be propagated with that velocity when once set going.

It may be noted that the elasticity E is only constant for small volume changes or for small values of dy/dx.

Since by definition $E = -v(dp/dv) = \rho(dp/d\rho)$ equation (6) becomes

$$U = \surd(dp/d\rho). \qquad (7)$$

The value $U = \surd(E/\rho)$ was first virtually obtained by Newton (*Principia*, bk. ii., § 8, props. 48–49). He supposed that in air Boyle's law holds in the extensions and compressions, or that $p = k\rho$, whence $dp/d\rho = k = p/\rho$. His value of the velocity in air is therefore

$$U = \surd(p/\rho) \qquad \text{(Newton's formula).}$$

At the standard pressure of 76 cm. of mercury or 1,014,000 dynes / sq. cm., the density of dry air at 0° C. being taken as 0·001293, we get for the velocity in dry air at 0° C.

$$U_0 = 28{,}000 \text{ cm.sec.} \qquad \text{(about 920 ft./sec.)}$$

approximately. Newton found 979 ft./sec. But, as we shall see, all the determinations give a value of U_0 in the neighbourhood of 33,000 cm./sec., or about 1080 ft./sec. This discrepancy was not explained till 1816, when Laplace (*Ann. de chimie*, 1816, vol. iii.) pointed out that the compressions and extensions in sound waves in air alternate so rapidly that there is no time for the temperature inequalities produced by them to spread. That is to say, instead of using Boyle's law, which supposes that the pressure changes so exceedingly slowly that conduction keeps the temperature constant, we must use the adiabatic relation $p=k\rho^\gamma$, whence

$$dp/d\rho=\gamma k\rho^{\gamma-1}=\gamma p/\rho,$$

and $$U=\sqrt{(\gamma p/\rho)} \quad \text{[Laplace's formula]}. \quad (8)$$

If we take $\gamma=1\cdot4$ we obtain approximately for the velocity in dry air at 0° C,

$$U_0=33,150 \text{ cm./sec.},$$

which is closely in accordance with observation. Indeed Sir G. G. Stokes (*Math. and Phys. Papers*, iii. 142) showed that a very small departure from the adiabatic condition would lead to a stifling of the sound quite out of accord with observation.

If we put $p=k\rho(1+\alpha t)$ in (8) we get the velocity in a gas at t° C,

$$U_t=\sqrt{\{\gamma k(1+\alpha t)\}}.$$

At 0° C. we have $U_0=\sqrt{(\gamma k)}$, and hence

$$U_t=U_0\sqrt{(1+\alpha t)}$$
$$=U_0(1+0\cdot00184t) \quad \text{(for small values of } t\text{)}. \quad (9)$$

The velocity then should be independent of the barometric pressure, a result confirmed by observation.

For two different gases with the same value of γ, but with densities at the same pressure and temperature respectively ρ_1 and ρ_2, we should have

$$U_1/U_2=\sqrt{(\rho_2/\rho_1)}, \quad (10)$$

another result confirmed by observation.

Alteration of Form of the Waves when Pressure Changes are Considerable.—When the value of dy/dx is not very small E is no longer constant, but is rather greater in compression and rather less in extension than γP. This can be seen by considering that the relation between p and ρ is given by a curve and not by a straight line. The consequence is that the compression travels rather faster, and the extension rather slower, than at the speed found above.

We may get some idea of the effect by supposing that for a short time the change in form is negligible. In the momentum equation (4) we may now omit X and it becomes

$$\omega+\rho(U-u)^2=\rho_0U^2.$$

Let us seek a more exact value for ω. If when P changes to $P+\omega$ volume V changes to $V-v$ then $(P+\omega)(V-v)^\gamma=PV^\gamma$,

whence $$\omega=P\left(\gamma\frac{v}{V}+\frac{\gamma(\gamma+1)}{2}\frac{v^2}{V^2}\right)=\gamma\frac{Pv}{V}\left(1+\frac{\gamma+1}{2}\frac{v}{V}\right).$$

We have $U-u=U(1-u/U)=U(1-v/V)$, since $u/U=-dy/dx=v/V$. Also since $\rho(V-v)=\rho_0V$, or $\rho=\rho_0/(1-v/V)$, then $\rho(U-u)^2=V\rho_0U^2(1-v/V)$.

Substituting in the momentum equation, we obtain

$$\gamma\frac{Pv}{V}\left(1+\frac{\gamma+1}{2}\frac{v}{V}\right)+\rho_0U^2\left(1-\frac{v}{V}\right)=\rho_0U^2,$$

whence $$U^2=\frac{\gamma P}{\rho_0}\left(1+\frac{\gamma+1}{2}\frac{u}{U}\right).$$

If $U=\sqrt{(\gamma P/\rho_0)}$ is the velocity for small disturbances, we may put U_0 for U in the small term on the right, and we have

$$U=U_0\left(1+\frac{\gamma+1}{4}\frac{u}{U_0}\right)$$

or $$U=U_0+\tfrac{1}{4}(\gamma+1)u. \quad (11)$$

This investigation is obviously not exact, for it assumes that the form is unchanged, *i.e.* that the momentum issuing from A (fig. 9) is equal to that entering at B, an assumption no longer tenable when the form changes. But for very small times the assumption may perhaps be made, and the result at least shows the way in which the velocity is affected by the addition of a small term depending on and changing sign with u. It implies that the different parts of a wave move on at different rates, so that its form must change. As we obtained the result on the supposition of unchanged form, we can of course only apply it for such short lengths and such short times that the part dealt with does not appreciably alter. We see at once that, where $u=0$, the velocity has its "normal" value, while where u is positive the velocity is in excess, and where u is negative the velocity is in defect of the normal value. If, then, a (fig. 10) represents the displacement curve of a train of waves, b will represent the pressure excess and particle velocity, and from (11) we see that while the nodal conditions of b, with $\hat\omega=0$ and $u=0$, travel with velocity $\sqrt{(E/\rho)}$, the crests exceed that velocity by $\frac{1}{4}(\gamma+1)u$, and the hollows fall short of it by $\frac{1}{4}(\gamma+1)u$, with the result that the fronts of the pressure waves become steeper and steeper, and the train b changes into something like c. If the steepness gets very great our investigation ceases to apply, and neither experiment nor theory has yet shown what happens. Probably there is a breakdown of the wave somewhat like the breaking of a water-wave when the crest gains on the next trough. In ordinary sound-waves the effect of the particle velocity in affecting the velocity of transmission must be very small.

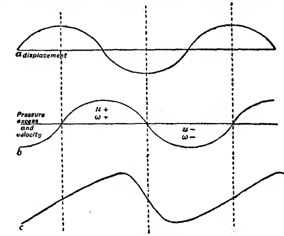

FIG. 10.

Experiments, referred to later, have been made to find the amplitude of swing of the air particles in organ pipes. Thus Mach found an amplitude 0·2 cm. when the issuing waves were 250 cm. long. The amplitude in the pipe was certainly much greater than in the issuing waves. Let us take the latter as 0·1 mm. in the waves—a very extreme value. The maximum particle velocity is $2\pi na$ (where n is the frequency and a the amplitude), or $2\pi aU/\lambda$. This gives maximum u=about 8 cm./sec., which would not seriously change the form of the wave in a few wave-lengths. Meanwhile the waves are spreading out and the value of u is falling in inverse proportion to the distance from the source, so that very soon its effect must become negligible.

In loud sounds, such as a peal of thunder from a near flash, or the report of a gun, the effect may be considerable, and the rumble of the thunder and the prolonged boom of the gun may perhaps be in part due to the breakdown of the wave when the crest of maximum pressure has moved up to the front, though it is probably due in part also to echo from the surfaces of heterogeneous masses of air. But there is no doubt that with very loud explosive sounds the normal velocity is quite considerably exceeded. Thus Regnault in his classical experiments (described below) found that the velocity of the report of a pistol carried through a pipe diminished with the intensity, and his results have been confirmed by J. Violle and T. Vautier (see below). W. W. Jacques (*Phil. Mag.*, 1879, 7, p. 219) investigated the transmission of a report from a cannon in different directions; he found that it rose to a maximum of 1267 ft./sec. at 70, to 90 ft. in the rear and then fell off.

A very curious observation is recorded by the Rev. G. Fisher in an appendix to Captain Parry's *Journal of a Second Voyage to the Arctic Regions*. In describing experiments on the velocity of sound he states that "on one day and one day only, February 9, 1822, the officer's word of command 'fire' was several times heard distinctly both by Captain Parry and myself about one beat of the chronometer [nearly half a second] *after* the report of the gun." This is hardly to be explained by equation (11), for at the very front of the disturbance $u=0$ and the velocity should be normal.

The Energy in a Wave Train.—The energy in a train of waves carried forward with the waves is partly strain or potential energy due to change of volume of the air, partly kinetic energy due to the motion of the air as the waves pass. We shall show that if we sum these up for a whole wave the potential energy is equal to the kinetic energy.

The kinetic energy per cubic centimetre is $\frac{1}{2}\rho u^2$, where ρ is the density and u is the velocity of disturbance due to the passage of the wave. If V is the undisturbed volume of a small portion of the air at the undisturbed pressure P, and if it becomes $V-v$ when the pressure increases to $P+\hat\omega$, the average pressure during the change may be taken as $P+\frac{1}{2}\hat\omega$, since the pressure excess for a small change is proportional to the change. Hence the work done on the air is $(P+\frac{1}{2}\hat\omega)v$, and the work done per cubic centimetre is $(P+\frac{1}{2}\hat\omega)v/V$. The term Pv/V added up for a complete wave vanishes, for P/V is constant and $\Sigma v=0$, since on the whole the compression equals the extension. We have then only to consider the term $\frac{1}{2}\hat\omega v/V$.

$$\begin{aligned}\text{But } v/V &= u/U \text{ from equation (2)}\\ \text{and } \hat\omega &= Eu/U \text{ from equation (3)}\\ \text{Then } \tfrac{1}{2}\hat\omega v/V &= \tfrac{1}{2}Eu^2/U^2=\tfrac{1}{2}\rho u^2 \text{ from equation (6)}\end{aligned}$$

Then in the whole wave the potential energy equals the kinetic energy and the total energy in a complete wave in a column 1 sq. cm. cross-section is $W=\int_0^\lambda \rho u^2dx$.

We may find here the value of this when we have a train of waves in which the displacement is represented by a sine curve of amplitude a, viz. $y=a \sin \frac{2\pi}{\lambda}(x-\mathrm{U}t)$. For a discussion of this type of wave, see below.

We have $$u=\frac{dy}{dt}=-\frac{2\pi}{\lambda}\mathrm{U}a \cos \frac{2\pi}{\lambda}(x-\mathrm{U}t),$$

and $$\int_0^\lambda \rho u^2 dx=\rho\frac{4\pi^2\mathrm{U}^2a^2}{\lambda^2}\int_0^\lambda \cos^2\frac{2\pi}{\lambda}(x-\mathrm{U}t)dx$$
$$=2\rho\pi^2\mathrm{U}^2a^2/\lambda \qquad (12)$$

The energy per cubic centimetre on the average is
$$2\rho\pi^2\mathrm{U}^2a^2/\lambda^2 \qquad (13)$$
and the energy passing per second through 1 sq. cm. perpendicular to the line of propagation is
$$2\rho\pi^2\mathrm{U}^3a^2/\lambda^2 \qquad (14)$$

The Pressure of Sound Waves.—Sound waves, like light waves, exercise a small pressure against any surface upon which they impinge. The existence of this pressure has been demonstrated experimentally by W. Altberg (*Ann. der Physik*, 1903, 11, p. 405). A small circular disk at one end of a torsion arm formed part of a solid wall, but was free to move through a hole in the wall slightly larger than the disk. When intense sound waves impinged on the wall, the disk moved back through the hole, and by an amount showing a pressure of the order given by the following investigation:—

Suppose that a train of waves is incident normally on the surface S (fig. 11), and that they are absorbed there without reflection.

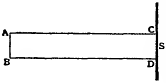

Fig. 11.

Let ABCD be a column of air 1 sq. cm. cross-section. The pressure on CD is equal to the momentum which it receives per second. On the whole the air within ABCD neither gains nor loses momentum, so that on the whole it receives as much through AB as it gives up to CD. If P is the undisturbed pressure and $\mathrm{P}+\bar{\omega}$ the pressure at AB, the momentum entering through AB per second is $\int_0^1(\mathrm{P}+\bar{\omega}+\rho u^2)dt$. But $\int_0^1 \mathrm{P}dt=\mathrm{P}$ is the normal pressure, and as we only wish to find the excess we may leave this out of account.

The excess pressure on CD is therefore $\int_0^1(\bar{\omega}+\rho u^2)dt$. But the values of $\bar{\omega}+\rho u^2$ which occur successively during the second at AB exist simultaneously at the beginning of the second over the distance U behind AB. Or if the conditions along this distance U could be maintained constant, and we could travel back along it uniformly in one second, we should meet all the conditions actually arriving at AB and at the same intervals. If then $d\xi$ is an element of the path, putting $dt=d\xi/\mathrm{U}$, we have the average excess of pressure
$$p=\int_0^1(\bar{\omega}+\rho u^2)dt=\frac{1}{\mathrm{U}}\int_0^{\mathrm{U}}(\bar{\omega}+\rho u^2)d\xi.$$

Here $d\xi$ is an actual length in the disturbance. We have $\bar{\omega}$ and u expressed in terms of the original length dx and the displacement dy so that we must put $d\xi=dx+dy=(1+dy/dx)dx$, and
$$p=\frac{1}{\mathrm{U}}\int_0^{\mathrm{U}}(\bar{\omega}+\rho u^2)\left(1+\frac{dy}{dx}\right)dx.$$

We have already found that if V changes to $\mathrm{V}-v$
$$\bar{\omega}=\gamma\mathrm{P}\left(\frac{v}{\mathrm{V}}+\frac{\gamma+1}{2}\frac{v^2}{\mathrm{V}^2}\right)=\rho_0\mathrm{U}^2\left\{-\frac{dy}{dx}+\frac{\gamma+1}{2}\left(\frac{dy}{dx}\right)^2\right\}$$
since $v/\mathrm{V}=-dy/dx$.

We also have $\rho u^2=\rho_0 u^2/(1+dy/dx)$. Substituting these values and neglecting powers of dy/dx above the second we get
$$p=\frac{1}{\mathrm{U}}\int_0^{\mathrm{U}}\rho_0\mathrm{U}^2\left\{-\frac{dy}{dx}+\frac{\gamma+1}{2}\left(\frac{dy}{dx}\right)^2\right\}dx.$$

But $\int_0^{\mathrm{U}}\frac{dy}{dx}dx=0$ since the sum of the displacements $=0$. Then putting $(dy/dx)^2=(u/\mathrm{U})^2$, we have
$$p=\frac{\gamma+1}{2}\cdot\frac{1}{\mathrm{U}}\int_0^{\mathrm{U}}\rho_0 u^2 dx$$
$$=\tfrac{1}{2}(\gamma+1)\text{ average energy per cubic centimetre,} \qquad (15)$$
a result first published by Lord Rayleigh (*Phil. Mag.*, 1905, 10, p. 364).

If the train of waves is reflected, the value of p at AB will be the sum of the values for the two trains, and will, on the average, be doubled. The pressure on CD will therefore be doubled. But the energy will also be doubled, so that (15) still gives the average excess of pressure

Experimental Determinations of the Velocity of Sound.

An obvious method of determining the velocity of sound in air consists in starting some sound, say by firing a gun, and stationing an observer at some measured distance from the gun. The observer measures by a clock or chronometer the time elapsing between the receipt of the flash, which passes practically instantaneously, and the receipt of the report. The distance divided by the time gives the velocity of the sound. The velocity thus obtained will be affected by the wind. For instance, William Derham (*Phil. Trans.*, 1708) made a series of observations, noting the time taken by the report of a cannon fired on Blackheath to travel across the Thames to Upminster Church in Essex, 12½ m. away. He found that the time varied between 55½ seconds when the wind was blowing most strongly with the sound, to 63 seconds when it was most strongly against the sound. The value for still air he estimated at 1142 ft. per second. He made no correction for temperature or humidity. But when the wind is steady its effect may be eliminated by "reciprocal" observations, that is, by observations of the time of passage of sound in each direction over the measured distance.

Let D be the distance, U the velocity of sound in still air, and w the velocity of the wind, supposed for simplicity to blow directly from one station to the other. Let T_1 and T_2 be the observed times of passage in the two directions. We have $\mathrm{U}+w=\mathrm{D}/\mathrm{T}_1$ and $\mathrm{U}-w=\mathrm{D}/\mathrm{T}_2$. Adding and dividing by 2
$$\mathrm{U}=\frac{\mathrm{D}}{2}\left(\frac{1}{\mathrm{T}_1}+\frac{1}{\mathrm{T}_2}\right).$$
If T_1 and T_2 are nearly equal, and if $\mathrm{T}=\frac{1}{2}(\mathrm{T}_1+\mathrm{T}_2)$, this is very nearly $\mathrm{U}=\mathrm{D}/\mathrm{T}$.

The reciprocal method was adopted in 1738 by a commission of the French Academy (*Mémoires de l'académie des sciences*, (1738). Cannons were fired at half-hour intervals, alternately at Montmartre and Montlhéry, 17 or 18 m. apart. There were also two intermediate stations at which observations were made. The times were measured by pendulum clocks. The result obtained at a temperature about 6° C. was, when converted to metres, U = 337 metres/second.

The theoretical investigation given above shows that if U is the velocity in air at t° C. then the velocity U_0 at 0° C. in the same air is independent of the barometric pressure and that $\mathrm{U}_0=\mathrm{U}/(1+0{\cdot}00184t)$, whence $\mathrm{U}_0=332$ met./sec.

In 1822 a commission of the Bureau des Longitudes made a series of experiments between Montlhéry and Villejuif, 11 m. apart. Cannons were fired at the two stations at intervals of five minutes. Chronometers were used for timing, and the result at 15·9° C. was U = 340·9 met./sec., whence U_0 = 330·6 met./sec. (F. J. D. Arago, *Connaissance des temps*, 1825).

When the measurement of a time interval depends on an observer, his "personal equation" comes in to affect the estimation of the quantity. This is the interval between the arrival of an event and his perception that it has arrived, or it may be the interval between arrival and his record of the arrival. This personal equation is different for different observers. It may differ even by a considerable fraction of a second. It is different, too, for different senses with the same observer, and different even for the same sense when the external stimuli differ in intensity. When the interval between a flash and a report is measured, the personal equations for the two arrivals are, in all probability, different, that for the flash being most likely less than that for the sound. In a long series of experiments carried out by V. Regnault in the years 1862 to 1866 on the velocity of sound in open air, in air in pipes and in various other gases in pipes, he sought to eliminate personal equation by dispensing with the human element in the observations, using electric receivers as observers. A short account of these experiments is given in *Phil. Mag.*, 1868, 35, p. 161, and the full account, which serves as an excellent example of the extraordinary care and ingenuity of Regnault's work, is given in the *Mémoires de l'académie des sciences*, 1868, xxxvii. On page 459 of the *Mémoire* will be found a list of previous careful experiments on the velocity of sound.

In the open-air experiments the receiver consisted of a large cone having a thin india-rubber membrane stretched over its narrow end. A small metal disk was attached to the centre of the membrane and connected to earth by a fine wire. A metal contact-piece adjustable by a screw could be made to just touch a point at the centre of the disk. When contact was made it completed an electric circuit which passed to a recording station, and there, by means of an electro-magnet, actuated a style writing a record on a band of travelling smoked paper. On the same band a tuning-fork electrically maintained and a seconds clock actuating another style wrote parallel records. The circuit was continued to the gun which served as a source, and stretched across its muzzle. When the gun was fired, the circuit was broken, and the break was recorded on the paper. The circuit was at once remade. When the wave travelled to the receiver it pushed back the disk from the contact-piece, and this break, too, was recorded. The time between the breaks could be measured in seconds by the clock signals, and in fractions of a second by the tuning-fork record. The receiving apparatus had what we may term a personal equation, for the break of contact could only take place when the membrane travelled some finite distance, exceedingly small no doubt, from the contact-piece. But the apparatus was used in such a way that this could be neglected. In some experiments in which contact was made instead of broken, Regnault determined the personal equation of the apparatus.

To eliminate wind as far as possible reciprocal firing was adopted, the interval between the two firings being only a few seconds. The temperature of the air traversed and its humidity were observed, and the result was finally corrected to the velocity in dry air at 0° C. by means of equation (10).

Regnault used two different distances, viz. 1280 metres and 2445 metres, obtaining from the first $U_0=331\cdot37$ met./sec.; but the number of experiments over the longer distance was greater, and he appears to have put more confidence in the result from them, viz.

$$U_0=330\cdot71 \text{ met./sec.}$$

In the *Phil. Trans.*, 1872, 162, p. 1, is given an interesting determination made by E. J. Stone at the Cape of Good Hope. In this experiment the personal equations of the observers were determined and allowed for.

Velocity of Sound in Air and other Gases in Pipes.—In the memoir cited above Regnault gives an account of determinations of the velocity in air in pipes of great length and of diameters ranging from 0·108 metres to 1·1 metres. He used various sources and the method of electric registration. He found that in all cases the velocity decreased with a diameter. The sound travelled to and fro in the pipes several times before the signals died away, and he found that the velocity decreased with the intensity, tending to a limit for very feeble sounds, the limit being the same whatever the source. This limit for a diameter 1·1 m. was $U_0=330\cdot6$ met./sec., while for a diameter 0·108 it was $U_0=324\cdot25$ met./sec.

Regnault also set up a shorter length of pipes of diameter 0·108 m. in a court at the Collège de France, and with this length he could use dry air, vary the pressure, and fill with other gases. He found that within wide limits the velocity was independent of the pressure, thus confirming the theory. Comparing the velocities of sound U_1 and U_2 in two different gases with densities ρ_1 and ρ_2 at the same temperature and pressure, and with ratios of specific heats γ_1, γ_2, theory gives

$$U_1/U_2=\sqrt{\{\gamma_1\rho_2/\gamma_2\rho_1\}}.$$

This formula was very nearly confirmed for hydrogen, carbon dioxide and nitrous oxide.

J. Violle and T. Vautier (*Ann. chim. phys.*, 1890, vol. 19) made observations with a tube 0·7 m. in diameter, and, using Regnault's apparatus, found that the velocity could be represented by

$$331\cdot3(1+C\sqrt{P}),$$

where P is the mean excess of pressure above the normal. According to von Helmholtz and Kirchhoff the velocity in a tube should be less than that in free air by a quantity depending on the diameter of the tube, the frequency of the note used, and the viscosity of the gas (Rayleigh, *Sound*, vol. ii. §§ 347–8). Correcting the velocity obtained in the 0·7 m. tube by Kirchhoff's formula, Violle and Vautier found for the velocity in open air at 0° C.

$$U_0=331\cdot10 \text{ met./sec.}$$

with a probable error estimated at $\pm$ 0·10 metre.

It is obvious from the various experiments that the velocity of sound in dry air at 0° C. is not yet known with very great accuracy. At present we cannot assign a more exact value than

$$\mathbf{U_0 = 331 \text{ metres per second.}}$$

Violle and Vautier made some later experiments on the propagation of musical sounds in a tunnel 3 metres in diameter (*Ann. chim. phys.*, 1905, vol. 5). They found that the velocity of propagation of different musical sounds was the same. Some curious effects were observed in the formation of harmonics in the rear of the primary tone used. These have yet to find an explanation.

Velocity of Sound in Water.—The velocity in water was measured by J. D. Colladon and J. K. F. Sturm (*Ann. chim. phys.*, 1827 (2), 36, p. 236) in the water of Lake Geneva. A bell under water was struck, and at the same instant some gunpowder was flashed in air above the bell. At a station more than 13 kilometres away a sort of big ear-trumpet, closed by a membrane, was placed with the membrane under water, the tube rising above the surface. An observer with his ear to the tube noted the interval between the arrival of flash and sound. The velocity deduced at 8·1° C. was $U=1435$ met./sec., agreeing very closely with the value calculated from the formula $U^2=E/\rho$.

Experiments on the velocity of sound in iron have been made on lengths of iron piping by J. B. Biot, and on telegraph wires by Wertheim and Brequet. The experiments were not satisfactory, and it is sufficient to say that the results accorded roughly with the value given by theory.

Reflection of Sound.

When a wave of sound meets a surface separating two media it is in part reflected, travelling back from the surface into the first medium again with the velocity with which it approached. Echo is a familiar example of this. The laws of reflection of sound are identical with those of the reflection of light, viz. (1) the planes of incidence and reflection are coincident, and (2) the angles of incidence and reflection are equal. Experiments may be made with plane and curved mirrors to verify these laws, but it is necessary to use short waves, in order to diminish diffraction effects. For instance, a ticking watch may be put at the focus of a large concave metallic mirror, which sends a parallel "beam" of sound to a second concave mirror facing the first. If an ear-trumpet is placed at the focus of the second mirror the ticking may be heard easily, though it is quite inaudible by direct waves. Or it may be revealed by placing a sensitive flame of the kind described below with its nozzle at the focus. The flame jumps down at every tick.

Examples of reflection of sound in buildings are only too frequent. In large halls the words of a speaker are echoed or reflected from flat walls or roof or floor; and these reflected sounds follow the direct sounds at such an interval that syllables and words overlap, to the confusion of the speech and the annoyance of the audience.

Some curious examples of echo are given in Herschel's article on "Sound" in the *Encyclopaedia Metropolitana*, but it appears that he is in error in one case. He states that in the whispering gallery in St Paul's, London, "the faintest sound is faithfully conveyed from one side to the other of the dome but is not heard at any intermediate point." In some domes, for instance in a dome at the university of Birmingham, a sound from one end of a diameter is heard very much more loudly quite close to the other end of the diameter than elsewhere, but in St Paul's Lord Rayleigh found that "the abnormal loudness with which a whisper is heard is not confined to the position diametrically opposite to that occupied by the whisperer, and therefore, it would appear, does not depend materially upon the symmetry of the dome. The whisper seems to creep round the gallery horizontally, not necessarily along the shorter arc, but rather along that arc towards which the whisperer faces. This is a consequence of the very unequal audibility of a whisper in front and behind the speaker, a phenomenon which may easily be observed in the open air" (*Sound*, ii. § 287).

Let fig. 12 represent a horizontal section of the dome through the source P. Let OPA be the radius through P. Let PQ represent a ray of sound making the angle θ with the tangent at A. Let ON($=$OP cos θ) be the perpendicular on PQ. Then the reflected ray QR and the ray reflected at R, and so on, will all touch the circle drawn with ON as radius. A ray making an angle less than θ with the tangent will, with its reflections, touch a larger circle. Hence all rays between $\pm\theta$ will be confined in the space between the outer dome and a circle of radius OP cos θ, and the weakening of intensity will be chiefly due to vertical spreading.

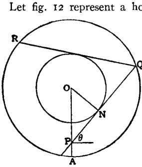

FIG. 12.

Rayleigh points out that this clinging of the sound to the surface of a concave wall does not depend on the exactness of the spherical form. He suggests that the propagation of earthquake disturbances is probably affected by the curvature of the surface of the globe, which may act like a whispering gallery.

In some cases of echo, when the original sound is a compound musical note, the octave of the fundamental tone is reflected much more strongly than that tone itself. This is explained by Rayleigh (*Sound*, ii. § 296) as a consequence of the irregularities of the reflecting surface. The irregularities send back a scattered reflection of the different incident trains, and this scattered reflection becomes more copious the shorter the wave-length. Hence the octave, though comparatively feeble in the incident train, may predominate in the scattered reflection constituting the echo.

Refraction of Sound.

When a wave of sound travelling through one medium meets a second medium of a different kind, the vibrations of its own particles are communicated to the particles of the new medium, so that a wave is excited in the latter, and is propagated through it with a velocity dependent on the density and elasticity of the second medium, and therefore differing in general from the previous velocity. The direction, too, in which the new wave travels is different from the previous one. This change of direction is termed *refraction*, and takes place, no doubt, according to the same laws as does the refraction of light, viz. (1) The new direction or *refracted ray* lies always in the *plane of incidence*, or plane which contains the incident ray (*i.e.* the direction of the wave in the first medium), and the normal to the surface separating the two media, at the point in which the incident ray meets it; (2) The *sine* of the angle between the normal and the incident ray bears to the *sine* of the angle between the normal and the refracted ray a ratio which is constant for the same pair of media. As with light the ratio involved in the second law is always equal to the ratio of the velocity of the wave in the first medium to the velocity in the second; in other words, the *sines* of the angles in question are *directly* proportional to the velocities.

Hence sound rays, in passing from one medium into another, are bent in towards the normal, or the reverse, according as the velocity of propagation in the former exceeds or falls short of that in the latter. Thus, for instance, sound is refracted *towards* the perpendicular when passing into air from water, or into carbonic acid gas from air; the converse is the case when the passage takes place the opposite way.

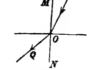

FIG. 13.

It further follows, as in the analogous case of light, that there is a certain angle termed the *critical angle*, whose sine is found by dividing the less by the greater velocity, such that all rays of sound meeting the surface separating two different bodies will not pass onward, but suffer total reflection back into the first body, if the velocity in that body is less than that in the other body, and if the angle of incidence exceeds the limiting angle.

The velocities in air and water being respectively 1090 and 4700 ft. the limiting angle for these media may be easily shown to be slightly above $15\frac{1}{2}°$. Hence, rays of sound proceeding from a distant source, and therefore nearly parallel to each other, and to PO (fig. 13), the angle POM being greater than $15\frac{1}{2}°$, will not pass into the water at all, but suffer total reflection. Under such circumstances, the report of a gun, however powerful, should be inaudible by an ear placed in the water.

Acoustic Lenses.—As light is concentrated into a focus by a convex glass lens (for which the velocity of light is less than for the air), so sound ought to be made to converge by passing through a convex lens formed of carbonic acid gas. On the other hand, to produce convergence with water or hydrogen gas, in both which the velocity of sound exceeds its rate in air, the lens ought to be concave. These results have been confirmed experimentally by K. F. J. Sondhauss (*Pogg. Ann.*, 1852, 85. p. 378), who used a collodion lens filled with carbonic acid. He found its focal length and hence the refractive index of the gas, C. Hajech (*Ann. chim. phys.*, 1858, (iii). vol. 54) also measured the refractive indices of various gases, using a prism containing the gas to be experimented on, and he found that the deviation by the prism agreed very closely with the theoretical values of sound in the gas and in air.

Temperature Refraction.

Osborne Reynolds (*Proc. Roy. Soc.*, 1874, 22, p. 531) first pointed out that refraction would result from a variation in the temperature of the air at different heights. The velocity of sound in air is independent of the pressure, but varies with the temperature, its value at $t°$ C. being as we have seen

$$U = U_0(1 + \tfrac{1}{2}at),$$

where U_0 is the velocity at 0° C., and a is the coefficient of expansion ·00365. Now if the temperature is higher overhead than at the surface, the velocity overhead is greater. If a wave front is in a given position, as a 1 (fig. 14), at a given instant

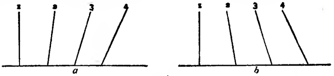

FIG. 14.

the upper part, moving faster, gains on the lower, and the front tends to swing round as shown by the successive positions in a 2, 3 and 4; that is, the sound tends to come down to the surface. This is well illustrated by the remarkable horizontal carriage of sound on a still clear frosty morning, when the surface layers of air are decidedly colder than those above. At sunset, too, after a warm day, if the air is still, the cooling of the earth by radiation cools the lower layers, and sound carries excellently over a level surface. But usually the lower layers are warmer than the upper layers, and the velocity below is greater than the velocity above. Consequently a wave front such as b 1 tends to turn upwards, as shown in the successive positions b 2, 3 and 4. Sound is then not so well heard along the level, but may still reach an elevated observer. On a hot summer's day the temperature of the surface layers may be much higher than that of the higher layers, and the effect on the horizontal carriage of sound may be very marked.

Refraction by Wind.

It is well known that sound travels far better with the wind than against it. Stokes showed that this effect is one of refraction, due to variation of velocity of the air from the surface upwards (*Brit. Assoc. Rep.*, 1857, p. 22). It is, of course, a matter of common observation that the wind increases in velocity from the surface upwards. An excellent illustration of this increase was pointed out by F. Osler in the shape of old clouds; their upper portions always appear dragged forward and they lean over, as it were, in the direction in which the wind is going. The same kind of thing happens with sound-wave fronts when travelling with the wind.

The velocity of any part of a wave front relative to the ground will be the normal velocity of sound + the velocity of the wind at that point. Since the velocity increases as we go upwards the front tends to swing round and travel downwards, as shown in the successive positions *a* 1, 2, 3 and 4, in fig. 14, where we must suppose the wind to be blowing from left to right. But if the wind is against the sound the velocity of a point of the wave front is the normal velocity—the wind velocity at the point, and so decreases as we rise. Then the front tends to swing round and travel upwards as shown in the successive positions *b* 1, 2, 3, and 4, in fig. 14, where the wind is travelling from right to left. In the first case the waves are more likely to reach and be perceived by an observer level with the source, while in the second case they may go over his head and not be heard at all.

Diffraction of Sound Waves.

Many of the well-known phenomena of optical diffraction may be imitated with sound waves, especially if the waves be short. Lord Rayleigh (*Scientific Papers*, iii. 24) has given various examples, and we refer the reader to his account. We shall only consider one interesting case of sound diffraction which may be easily observed. When we are walking past a fence formed by equally-spaced vertical rails or overlapping boards, we may often note that each footstep is followed by a musical ring. A sharp clap of the hands may also produce the effect. A short impulsive wave travels towards the fence, and each rail as it is reached by the wave becomes the centre of a new secondary wave sent out all round, or at any rate on the front side of the fence.

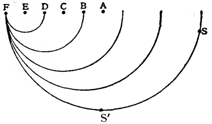

FIG. 15.

Let S (fig. 15) be the source very nearly in the line of the rails ABCDEF. At the instant that the original wave reaches F the wave from E has travelled to a circle of radius very nearly equal to EF—not quite, as S is not quite in the plane of the rails. The wave from D has travelled to a circle of radius nearly equal to DF, that from C to a circle of radius nearly CF, and so on. As these "secondary waves" return to S their distance apart is nearly equal to twice the distance between the rails, and the observer then hears a note of wave-length nearly 2EF. But if an observer is stationed at S′ the waves will be about half as far apart and will reach him with nearly twice the frequency, so that he hears a note about an octave higher. As he travels further round the frequency increases still more. The railings in fact do for sound what a diffraction grating does for light.

Frequency and Pitch.

Sounds may be divided into noises and musical notes. A mere noise is an irregular disturbance. If we study the source producing it we find that there is no regularity of vibration. A musical note always arises from a source which has some regularity of vibration, and which sends equally-spaced waves into the air. A given note has always the same frequency, that is to say, the hearer receives the same number of waves per second whatever the source by which the note is produced. Various instruments have been devised which produce any desired note, and which are provided with methods of counting the frequency of vibration. The results obtained fully confirm the general law that "pitch," or the position of the note in the musical scale, depends solely on its frequency. We shall now describe some of the methods of determining frequency.

Savart's toothed wheel apparatus, named after Félix Savart (1791–1841), a French physicist and surgeon, consists of a brass wheel, whose edge is divided into a number of equal projecting teeth distributed uniformly over the circumference, and which is capable of rapid rotation about an axis perpendicular to its plane and passing through its centre, by means of a series of multiplying wheels, the last of which is turned round by the hand. The toothed wheel being set in motion, the edge of a card or of a funnel-shaped piece of common notepaper is held against the teeth, when a note will be heard arising from the rapidly succeeding displacements of the air in its vicinity. The pitch of this note will rise as the rate of rotation increases, and becomes steady when that rotation is maintained uniform. It may thus be brought into unison with any sound of which it may be required to determine the corresponding number of vibrations per second, as for instance the note A_3, three octaves higher than the A which is indicated musically by a small circle placed between the second and third lines of the G clef, which A is the note of the tuning-fork usually employed for regulating concert-pitch. A_3 may be given by a piano. Now, suppose that the note produced with Savart's apparatus is in unison with A_3, when the experimenter turns round the first wheel at the rate of 60 turns per minute or one per second, and that the circumferences of the various multiplying wheels are such that the rate of revolution of the toothed wheel is thereby increased 44 times, then the latter wheel will perform 44 revolutions in a second, and hence, if the number of its teeth be 80, the number of taps imparted to the card every second will amount to 44×80 or 3520. This, therefore, is the number of vibrations corresponding to the note A_3. If we divide this by 2^3 or 8, we obtain 440 as the number of vibrations answering to the note A. If, for the single toothed wheel, be substituted a set of four with a common axis, in which the teeth are in the ratios 4: 5: 6: 8, and if the card be rapidly passed along their edges, we shall hear distinctly produced the fundamental chord C, E, G, C_1 and shall thus satisfy ourselves that the intervals C, E; C, G and C, C_1 are $\frac{5}{4}$, $\frac{3}{2}$ and 2 respectively.

Neither this instrument nor the next to be described is now used for exact work; they merely serve as illustrations of the law of pitch.

Seebeck's Siren.

The *siren* of L. F. W. A. Seebeck (1805–1849) is the simplest form of apparatus thus designated, and consists of a large circular disk mounted on a central axis, about which it may be made to revolve with moderate rapidity. This disk is perforated with small round holes arranged in circles about the centre of the disk. In the first series of circles, reckoning from the centre the openings are so made as to divide the respective circumferences, on which they are found, in aliquot parts bearing to each other the ratios of the numbers 2, 4, 5, 6, 8, 10, 12, 16, 20, 24, 32, 40, 48, 64. The second series consists of circles each of which is formed of two sets of perforations, in the first circle arranged as 4:5, in the next as 3:4, then as 2:3, 3:5, 4:7. In the outer series is a circle divided by perforations into four sets, the numbers of aliquot parts being as 3 : 4 : 5 : 6, followed by others which we need not further refer to.

The disk being started, then by means of a tube held at one end between the lips, and applied near to the disk at the other, or more easily with a common bellows, a blast of air is made to fall on the part of the disk which contains any one of the above circles. The current being alternately transmitted and shut off, as a hole passes on and off the aperture of the tube or bellows, causes a vibratory motion of the air, whose frequency depends on the number of times per second that a perforation passes the mouth of the tube. Hence the note produced with any given circle of holes rises in pitch as the disk revolves more rapidly; and if, the revolution of the disk being kept as steady as possible, the tube be passed rapidly across the circles of the first series, a series of notes is heard, which, if the lowest be denoted by C, form the sequence C, C_1, E_1, G_1, C_2, &c. In like manner, the first circle in which we have two sets of holes dividing the circumference, the one into say 8 parts, and the other into 10, or in ratio 4:5, the note produced is a compound one, such as would be obtained by striking on the piano two notes separated by the interval of a major third ($\frac{5}{4}$). Similar results are obtainable by means of the remaining perforations.

A still simpler form of siren may be constituted with a good spinning-top, a perforated card disk, and a tube for blowing with.

Siren of Cagniard de la Tour.

The siren of C. Cagniard de la Tour is founded on the same principle as the preceding. It consists of a cylindrical chest of brass, the base of which is pierced at its centre with an opening in which is fixed a brass tube projecting outwards, and intended for supplying the cavity of the cylinder with compressed air or other gas, or even liquid. The top of the cylinder is formed of a plate perforated near its edge by holes distributed uniformly in a circle concentric with the plate, and which are cut obliquely through the thickness of the plate. Immediately above this fixed plate, and almost in contact with it, is another of the same dimensions, and furnished with the same number, *n*, of openings similarly placed, but passing obliquely through in an opposite direction from those in the fixed plate, the one set being inclined to the left, the other to the right.

This second plate is capable of rotation about an axis perpendicular to its plane and passing through its centre. Now, let the movable plate be at any time in a position such that its holes are immediately above those in the fixed plate, and let the bellows by which air is forced into the cylinder (air, for simplicity, being supposed to be the fluid employed) be put in action; then the air in its passage will strike the side of each opening in the movable plate in an oblique direction (as shown in fig. 16), and will therefore urge the latter to rotation round its centre. After $1/n$th of a revolution, the two sets of perforations will again coincide, the lateral impulse of the air repeated, and hence the rapidity of rotation increased. This will go on continually as long as air is supplied to the cylinder, and the velocity of rotation of the upper plate will be accelerated up to a certain maximum, at which it may be maintained by keeping the force of the current constant.

Fig. 16.

Now, it is evident that each coincidence of the perforations in the two plates is followed by a non-coincidence, during which the air-current is shut off, and that consequently, during each revolution of the upper plate, there occur n alternate passages and interceptions of the current. Hence arises the same number of successive impulses of the external air immediately in contact with the movable plate, which is thus thrown into a state of vibration at the rate of n for every revolution of the plate. The result is a note whose pitch rises as the velocity of rotation increases, and becomes steady when that velocity reaches its constant value. If, then, we can determine the number m of revolutions performed by the plate in every second, we shall at once have the number of vibrations per second corresponding to the audible note by multiplying m by n.

For this purpose the axis is furnished at its upper part with a screw working into a toothed wheel, and driving it round, during each revolution of the plate, through a space equal to the interval between two teeth. An index resembling the hand of a watch partakes of this motion, and points successively to the divisions of a graduated dial. On the completion of each revolution of this toothed wheel (which, if the number of its teeth be 100, will comprise 100 revolutions of the movable plate), a projecting pin fixed to it catches a tooth of another toothed wheel and turns it round, and with it a corresponding index which thus records the number of turns of the first toothed wheel. As an example of the application of this siren, suppose that the number of revolutions of the plate, as shown by the indices, amounts to 5400 in a minute, that is, to 90 per second, then the number of vibrations per second of the note heard amounts to $90n$, or (if number of holes in each plate = 8) to 720.

Dove's Siren.

H. W. Dove (1803–1879) produced a modification of the siren by which the relations of different musical notes may be more readily ascertained. In it the fixed and movable plates are each furnished with four concentric series of perforations, dividing the circumferences into different aliquot parts, as, for example, 8, 10, 12, 16. Beneath the lower or fixed plate are four metallic rings furnished with holes corresponding to those in the plates, and which may be pushed round by projecting pins, so as to admit the air-current through any one or more of the series of perforations in the fixed plate. Thus may be obtained, either separately or in various combinations, the four notes whose vibrations are in the ratios of the above numbers, and which therefore form the fundamental chord ($CEGC_1$). The inventor has given to this instrument the name of the *many-voiced siren*.

Helmholtz's Double Siren.

Helmholtz (*Sensations of Tone*, ch. viii.) further adapted the siren for more extensive use, by the addition to Dove's instrument of another chest containing its own fixed and movable perforated plates and perforated rings, both the movable plates being driven by the same current and revolving about a common axis. Annexed is a figure of this instrument (fig. 17).

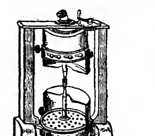

Fig. 17.

Graphic Methods.—The relation between the pitch of a note and the frequency of the corresponding vibrations has also been studied by *graphic* methods. Thus, if an elastic metal slip or a pig's bristle be attached to one prong of a tuning-fork, and if the fork, while in vibration, is moved rapidly over a glass plate coated with lamp-black, the attached style touching the plate lightly, a wavy line will be traced on the plate answering to the vibrations to and fro of the fork. The same result will be obtained with a stationary fork and a movable glass plate; and, if the time occupied by the plate in moving through a given distance can be ascertained and the number of complete undulations exhibited on the plate for that distance, which is evidently the number of vibrations of the fork in that time, is reckoned, we shall have determined the numerical vibration-value of the note yielded by the fork. Or, if the same plate be moved in contact with two tuning-forks, we shall, by comparing the number of sinuosities in the one trace with that in the other, be enabled to assign the ratio of the corresponding numbers of vibrations per second. Thus, if the one note be an octave higher than the other, it will give double the number of waves in the same distance. The motion of the plate may be simply produced by dropping it between two vertical grooves, the tuning-forks being properly fixed to a frame above.

The Revolving Drum.

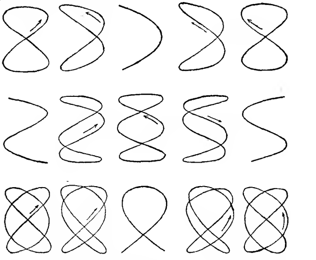
Greater accuracy may be attained with a revolving-drum chronograph first devised by Thomas Young (*Lect. on Nat. Phil.*, 1807, i. 190), consisting of a cylinder which may be coated with lamp-black, or, better still, a metallic cylinder round which a blackened sheet of paper is wrapped. The cylinder is mounted on an axis and turned round, while the style attached to the vibrating body is in light contact with it, and traces therefore a wavy circle, which, on taking off the paper and flattening it, becomes a wavy straight line. The superiority of this arrangement arises from the comparative facility with which the number of revolutions of the cylinder in a given time may be ascertained. In R. Koenig's arrangement (*Quelques expériences d'acoustique*, p. 1) the axis of the cylinder is fashioned as a screw, which works in fixed nuts at the ends, causing a sliding as well as a rotatory motion of the cylinder. The lines traced out by the vibrating pointer are thus prevented from overlapping when more than one turn is given to the cylinder. In the phonautograph of E. L. Scott (*Comptes rendus*, 1861, 53, p. 108) any sound whatever may be made to record its trace on the paper by means of a large parabolic cavity resembling a speaking-trumpet, which is freely open at the wider extremity, but is closed at the other end by a thin stretched membrane. To the centre of this membrane is attached a small feather-fibre, which, when the reflector is suitably placed, touches lightly the surface of the revolving cylinder. Any sound (such as that of the human voice) transmitting its rays into the reflector, and communicating vibratory motion to the membrane, will cause the feather to trace a sinuous line on the paper. If, at the same time, a tuning-fork of known number of vibrations per second be made to trace its own line close to the other, a comparison of the two lines gives the number corresponding to the sound under consideration. The phonograph (*q.v.*) may be regarded as an instrument of this class, in that it records vibrations on a revolving drum or disk.

Lissajous Figures.—A mode of exhibiting the ratio of the frequencies of two forks was devised by Jules Antoine Lissajous (1822–1880). On one prong of each fork is fixed a small plane mirror. The two forks are fixed so that one vibrates in a vertical, and the other in a horizontal, plane, and they are so placed that a converging beam of light received on one mirror is reflected to the other and then brought to a point on a screen. If the first fork alone vibrates, the point on the screen appears lengthened out into a vertical line through the changes in inclination of the first mirror, while if the second fork alone vibrates, the point appears lengthened out into a horizontal line. If both vibrate, the point describes a curve which appears continuous through the persistence of the retinal impression. Lissajous also obtained the figures by aid of the vibration microscope, an instrument which he invented. Instead of a mirror, the objective of a microscope is attached to one prong of the first fork and the eyepiece of the microscope is fixed behind the fork. Instead of a mirror the second fork carries a bright point on one prong, and the microscope is focused on this. If both forks vibrate, an observer looking through the microscope sees the bright point describing Lissajous figures. If the two forks have the same frequency, it is easily seen that the figure will be an ellipse (including as limiting cases, depending on relative amplitude and phase, a circle and a straight line). If the forks are not of exactly the same frequency the ellipse will slowly revolve, and from its rate of revolution the ratio of the frequencies may be determined (Rayleigh, *Sound*, i. § 33). If one is the octave of the other a figure of 8 may be described, and so on. Fig. 18 shows curves given by intervals of the octave, the twelfth and the fifth.

The kaleidophone devised by Charles Wheatstone in 1827 gives these figures in a simple way. It consists of a straight rod clamped in a vice and carrying a bead at its upper free end. The bead is illuminated and shows a bright point of light. If the rod is circular in section and perfectly uniform the end will describe a circle, ellipse or straight line; but, as the elasticity is usually not exactly the same in all directions, the figure usually changes and revolves. Various modifications of the kaleidophone have been made (Rayleigh, *Sound*, § 38).

Koenig's Tuning-fork Clock.

Koenig devised a clock in which a fork of frequency 64 takes the place of the pendulum (*Wied. Ann.*, 1880, ix. 394). The motion of the fork is maintained by the clock acting through an escapement, and the dial registers both the number of vibrations of the fork and the seconds, minutes and hours. By comparison with a clock of known rate the total number of vibrations of the fork in any time may be accurately determined. One prong of the fork carries a microscope objective, part of a vibration microscope, of which the eyepiece is fixed at the back of the clock and the Lissajous figure made by the clock fork and any other fork may be observed. With this apparatus Koenig studied the effect of temperature on a standard fork of 256 frequency, and found that the frequency decreased by 0·0286 of a vibration for a rise of 1°, the frequency being exactly 256 at 26·2° C. Hence the frequency may be put as $256\{1-0{\cdot}000113\,(t-26{\cdot}2)\}$.



(From Lord Rayleigh's *Theory of Sound*, by permission of Macmillan & Co., Ltd.)

FIG. 18.

Koenig also used the apparatus to investigate the effect on the frequency of a fork of a resonating cavity placed near it. He found that when the pitch of the cavity was below that of the fork the pitch of the fork was raised, and vice versa. But when the pitch of the cavity was exactly that of the fork when vibrating alone, though it resounded most strongly, it did not affect the frequency of the fork. These effects have been explained by Lord Rayleigh (*Sound*, i. § 117).

M'Leod and Clarke's Stroboscopic Method.

In the stroboscopic method of H. M'Leod and G. S. Clarke, the full details of which will be found in the original memoir (*Phil. Trans.*, 1880, pt. i. p. 1), a cylinder is ruled with equidistant white lines parallel to the axis on a black ground. It is set so that it can be turned at any desired and determined speed about a horizontal axis, and when going fast enough it appears grey. Imagine now that a fork with black prongs is held near the cylinder with its prongs vertical and the plane of vibration parallel to the axis, and suppose that we watch the outer outline of the right-hand prong. Let the cylinder be rotated so that each white line moves exactly into the place of the next while the prong moves once in and out. Hence when a white line is in a particular position on the cylinder, the prong will always be the same distance along it and cut off the same length from view. The most will be cut off in the position of the lines corresponding to the furthest swing out, then less and less till the furthest swing in, then more and more till the furthest swing out, when the appearance will be exactly as at first. The boundary between the grey cylinder and the black fork will therefore appear wavy with fixed undulations, the distance from crest to crest being the distance between the lines on the cylinder. If the fork has slightly greater frequency, then a white line will not quite reach the next place while the fork is making its swing in and out, and the waves will travel against the motion of the cylinder. If the fork has slightly less frequency the waves will travel in the opposite direction, and it is easily seen that the frequency of the fork is the number of white lines passing a point in a second $\pm$ the number of waves passing the point per second. This apparatus was used to find the temperature coefficient of the frequency of forks, the value obtained $-{\cdot}00011$ being the same as that found by Koenig. Another important result of the investigation was that the phase of vibration of the fork was not altered by bowing it, the amplitude alone changing. The method is easily adapted for the converse determination of speed of revolution when the frequency of a fork is known.

Rayleigh's Phonic Wheel.

The phonic wheel, invented independently by Paul La Cour and Lord Rayleigh (see *Sound*, i. § 68 *c*), consists of a wheel carrying several soft-iron armatures fixed at equal distances round its circumference. The wheel rotates between the poles of an electro-magnet, which is fed by an intermittent current such as that which is working an electrically maintained tuning-fork (see *infra*). If the wheel be driven at such rate that the armatures move one place on in about the period of the current, then on putting on the current the electro-magnet controls the rate of the wheel so that the agreement of period is exact, and the wheel settles down to move so that the electric driving forces just supply the work taken out of the wheel. If the wheel has very little work to do it may not be necessary to apply driving power, and uniform rotation may be maintained by the electro-magnet. In an experiment described by Rayleigh such a wheel provided with four armatures was used to determine the exact frequency of a driving fork known to have a frequency near 32. Thus the wheel made about 8 revolutions per second. There was one opening in its disk, and through this was viewed the pendulum of a clock beating seconds. On the pendulum was fixed an illuminated silver bead which appeared as a bright point of light when seen for an instant. Suppose now an observer to be looking from a fixed point at the bead through the hole in the phonic wheel, he will see the bead as 8 bright points flashing out in each beat, and in succession at intervals of $\frac{1}{8}$ second. Let us suppose that he notes the positions of two of these next to each other in the beat of the pendulum one way. If the fork makes exactly 32 vibrations and the wheel 8 revolutions in one pendulum beat, then the positions will be fixed, and every two seconds, the time of a complete pendulum vibration, he will see the two positions looked at flash out in succession at an interval of $\frac{1}{8}$ second. But if the fork has, say, rather greater frequency, the hole in the wheel comes round at the end of the two seconds before the bead has quite come into position, and the two flashes appear gradually to move back in the opposite way to the pendulum. Suppose that in N beats of the clock the flashes have moved exactly one place back. Then the first flash in the new position is viewed by the 8Nth passage of the opening, and the second flash in the original position of the first is viewed when the pendulum has made exactly N beats and by the $(8\,\mathrm{N}+1)$th passage of the hole. Then the wheel makes $8\,\mathrm{N}+1$ revolutions in N clock beats, and the fork makes $32\,\mathrm{N}+4$ vibrations in the same time. If the clock is going exactly right, this gives a frequency for the fork of $32+4/\mathrm{N}$. If the fork has rather less frequency than 32 then the flashes appear to move forward and the frequency will be $32-4/\mathrm{N}$. In Rayleigh's experiment the 32 fork was made to drive electrically one of frequency about 128, and somewhat as with the phonic wheel, the frequency was controlled so as to be exactly four times that of the 32 fork. A standard 128 fork could then be compared either optically or by beats with the electrically driven fork.

Scheibler's Tonometer.—When two tones are sounded together with frequencies not very different, "beats" or swellings-out of the sound are heard of frequency equal to the difference of frequencies of the two tones (see below). Johann Heinrich Scheibler (1777–1838) tuned two forks to an exact octave, and then prepared a number of others dividing the octave into such small steps that the beats between each and the next could be counted easily. Let the forks be numbered 0, 1, 2, . . . N. If the frequency of 0 is n, that of N is $2n$. Suppose that No. 1 makes m_1 beats with No. 0, that No. 2 makes m_2 beats with No. 1, and so on, then the frequencies are

$$n,\ n+m_1,\ n+m_1+m_2,\ \ldots,\ n+m_1+m_2+\ \ldots\ +m_{\mathrm{N}}.$$

Since $n+m_1+m_2+\ \ldots\ +m_{\mathrm{N}}=2n,\ n=m_1+m_2+\ \ldots\ +m_{\mathrm{N}}$,

and it follows that when n is known, the frequency of every fork in the range may be determined.

Any other fork within this octave can then have its frequency determined by finding the two between which it lies. Suppose, for instance, it makes 3 beats with No. 10, it might have frequency either 3 above or below that of No. 10. But if it lies above No. 10 it will beat less often with No. 11 than with No. 9; if below No. 10 less often with No. 9 than with No. 11. Suppose it lies between No. 10 and No. 11 its frequency is that of No. 10+3.

Manometric Flames.—This is a device due to Koenig (*Phil. Mag.*, 1873, 45) and represented diagrammatically in fig. 19. f is a flame

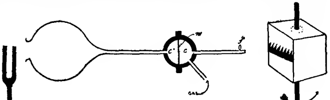


FIG. 19.

from a pinhole burner, fed through a cavity C, one side of which is closed by a membrane m; on the other side of the membrane is another cavity C′, which is put into connexion with a source of sound, as, for instance, a Helmholtz resonator excited by a fork of the same frequency. The membrane vibrates, and alternately checks and increases the gas supply, and the flame jumps up and down with the frequency of the source. It then appears elongated. To show its intermittent character its reflection is viewed in a revolving mirror. For this purpose four vertical mirrors are arranged round the vertical sides of a cube which is rapidly revolved about a vertical axis. The flame then appears toothed as shown. If several notes are present the flame is jagged by each. Interesting results are obtained by singing the different vowels into a funnel substituted for the resonator in the figure.

If two such flames are placed one under the other they may be excited by different sources, and the ratio of the frequencies may be approximately determined by counting the number of teeth in each in the same space.

The Diatonic Scale.

It is not necessary here to deal generally with the various musical scales. We shall treat only of the diatonic scale, which is the basis of European music, and is approximated to as closely as is consistent with convenience of construction in key-board instruments, such as the piano, where the eight white notes beginning with C and ending with C an octave higher may be taken as representing the scale with C as the key-note.

All experiments in frequency show that two notes, forming a definite musical interval, have their frequencies always in the same ratio wherever in the musical scale the two notes are situated. In the scale of C the intervals from the key-note, the frequency ratios with the key-note, the successive frequency ratios and the successive intervals are as follows:—

Note	C	D	E	F	G	A	B	C
Interval with C		second	major third	fourth	fifth	major sixth	seventh	octave
Frequency	1	$\frac{9}{8}$	$\frac{5}{4}$	$\frac{4}{3}$	$\frac{3}{2}$	$\frac{5}{3}$	$\frac{15}{8}$	2
Successive frequency ratios.		$\frac{9}{8}$	$\frac{10}{9}$	$\frac{16}{15}$	$\frac{9}{8}$	$\frac{10}{9}$	$\frac{9}{8}$	$\frac{16}{15}$
Successive intervals		major tone	minor tone	major semi-tone	major tone	minor tone	major tone	major semi-tone

If we pass through two intervals in succession, as, for instance, if we ascend through a fourth from C to F and then through a third from F to A, the frequency ratio of A to C is $\frac{5}{3}$, which is the product of the ratios for a fourth $\frac{4}{3}$, and a third $\frac{5}{4}$. That is, if we add intervals we must multiply frequency ratios to obtain the frequency ratio for the interval which is the sum of the two.

The frequency ratios in the diatonic scale are all expressible either as fractions, with 1, 2, 3 or 5 as numerator and denominator, or as products of such fractions; and it may be shown that for a given note the numerator and denominator are smaller than any other numbers which would give us a note in the immediate neighbourhood.

Thus the second $\frac{9}{8}=\frac{3}{2}\times\frac{3}{2}\times\frac{1}{2}$, and we may regard it as an ascent through two fifths in succession and then a descent through an octave. The third $\frac{5}{4}=5\times\frac{1}{2}\times\frac{1}{2}$ or ascent through an interval $\frac{5}{1}$, which has no special name, and a descent through two octaves, and so on.

Now suppose we take G as the key-note and form its diatonic scale. If we write down the eight notes from G to *g* in the key of C, their frequency ratios to C, the frequency ratios required by the diatonic scale for G, we get the frequency ratios required in the last line:—

Notes on scale of C	G	A	B	*c*	*d*	*e*	*f*	*g*
Frequency ratios with C = 1	$\frac{3}{2}$	$\frac{5}{3}$	$\frac{15}{8}$	2	$\frac{9}{4}$	$\frac{5}{2}$	$\frac{8}{3}$	3
Frequency ratios of diatonic scale with G = 1	1	$\frac{9}{8}$	$\frac{5}{4}$	$\frac{4}{3}$	$\frac{3}{2}$	$\frac{5}{3}$	$\frac{15}{8}$	2
Frequency ratios with C = 1, G = $\frac{3}{2}$	$\frac{3}{2}$	$\frac{27}{16}$	$\frac{15}{8}$	2	$\frac{9}{4}$	$\frac{5}{2}$	$\frac{45}{16}$	3

We see that all but two notes coincide with notes on the scale of C. But instead of A $=\frac{5}{3}$ we have $\frac{27}{16}$, and instead of $f=\frac{8}{3}$ we have $\frac{45}{16}$. The interval between $\frac{5}{3}$ and $\frac{27}{16}=\frac{27}{16}\div\frac{5}{3}=\frac{81}{80}$ is termed a "comma," and is so small that the same note on an instrument may serve for both. But the interval between $\frac{8}{3}$ and $\frac{45}{16}=\frac{45}{16}\div\frac{8}{3}=\frac{135}{128}$ is quite perceptible, and on the piano, for instance, a separate string must be provided above *f*. This note is *f* sharp, and the interval $\frac{135}{128}$ is termed a sharp.

Taking the successive key-notes D, A, E, B, it is found that besides small and negligible differences, each introduces a new sharp, and so we get the five sharps, C, D, F, G, A, represented nearly by the black keys.

If we start with F as key-note, besides a small difference at *d*, we have as the fourth from it $\frac{4}{3}\times\frac{4}{3}=\frac{16}{9}$, making with B $=\frac{15}{8}$ an interval $\frac{135}{128}$, and requiring a new note, B flat. This does not coincide with A sharp which is the octave below the seventh from B or $\frac{15}{8}\times\frac{15}{8}\times\frac{1}{2}=\frac{225}{128}$. It makes with it an interval $=\frac{16}{9}\div\frac{225}{128}=\frac{2048}{2025}$, rather less than a comma; so that the same string in the piano may serve for both. If we take the new note B flat as key-note, another note, E flat, is required. E flat as key-note introduces another flat, and so on, each flat not quite coinciding with a sharp but at a very small interval from it.

It is evident that for exact diatonic scales for even a limited number of key-notes, key-board instruments would have to be provided with a great number of separate strings or pipes, and the corresponding keys would be required. The construction would be complicated and the playing exceedingly difficult. The same string or pipe and the same key have therefore to serve for what should be slightly different notes. A compromise has to be made, and the note has to be tuned so as to make the compromise as little unsatisfactory as possible. At present twelve notes are used in the octave, and these are arranged at equal intervals $2^{\frac{1}{12}}$. This is termed the *equal temperament scale*, and it is obviously only an approach to the diatonic scale.

Helmholtz's Notation.—In works on sound it is usual to adopt Helmholtz's notation, in which the octave from bass to middle C is written *c d e f g a b c'*. The octave above is *c' d' e' f' g' a' b' c"*. The next octave above has two accents, and each succeeding octave another accent. The octave below bass C is written C D E F G A B *c*. The next octave below is C_1 D_1 E_1 F_1 G_1 A_1 B_1 C, and each preceding octave has another accent as suffix. *The standard frequency* for laboratory work is $c=128$, so that middle $c'=256$ and treble $c''=512$.

The standard for musical instruments has varied (see PITCH, MUSICAL). Here it is sufficient to say that the French standard is $a'=435$ with c'' practically 522, and that in England the pitch is somewhat higher.

The French notation is as under:—

C D E F G A B c
Ut$_1$ Re$_1$ M$_1$ Fa$_1$ Sol$_1$ La$_1$ Si$_1$ Ut$_2$.

The next higher octave has the suffix 2, the next higher the suffix 3, and so on. French forks are marked with double the true frequency, so that Ut$_3$ is marked 512.

Limiting Frequencies for Musical Sounds.—Until the vibrations of a source have a frequency in the neighbourhood of 30 per second the ear can hear the separate impulses, if strong enough, but does not hear a note. It is not easy to determine the exact point at which the impulses fuse into a continuous tone, for higher tones are usually present with the deepest of which the frequency is being counted, and these may be mistaken for it. Helmholtz (*Sensations of Tone*, ch. ix.) used a string loaded at the middle point so that the higher tones were several octaves above the fundamental, and so not likely to be mistaken for it; he found that with 37 vibrations per second a very weak sensation of tone was heard, but with 34 there was scarcely anything audible left. A determinate musical pitch is not perceived, he says, till about 40 vibrations per second. At the other end of the scale with increasing frequency there is another limiting frequency somewhere about 20,000 per second, beyond which no sound is heard. But this limit varies greatly with different individuals and with age for the same individual. Persons who when young could hear the squeaks of bats may be quite deaf to them when older. Koenig constructed a series of bars forming a harmonicon, the frequency of each bar being calculable, and he found the limit to be between 16,000 and 24,000.

The Number of Vibrations needed to give the Perception of Pitch.—Experiments have been made on this subject by various workers, the most extensive by W. Kohlrausch (*Wied. Ann.*, 1880, x. 1). He allowed a limited number of teeth on the arc of a circle to strike against a card. With sixteen teeth the pitch was well defined; with nine teeth it was fairly determinate; and even with two teeth it could be assigned with no great error. His remarkable result that two waves give some sense of pitch, in fact a tone with wave-length equal to the interval between the waves, has been confirmed by other observers.

Alteration of Pitch with Motion of Source or Hearer: Doppler's Principle.—A very noticeable illustration of the alteration of pitch by motion occurs when a whistling locomotive moves rapidly past an observer. As it passes, the pitch of the whistle falls quite appreciably. The explanation is simple. The engine follows up any wave that it has sent forward, and so crowds up the succeeding waves into a less distance than if it remained at rest. It draws off from any wave it has sent backward and so spreads the succeeding waves over a longer distance than if it had remained at rest. Hence the forward waves are shorter and the backward waves are longer. Since $U=n\lambda$ where U is the velocity of sound, λ the wave-length, and *n* the frequency, it follows that the forward frequency is greater than the backward frequency.

The more general case of motion of source, medium and receiver may be treated very easily if the motions are all in the line joining source and receiver. Let S (fig. 20) be the source at a given instant, and let its frequency of vibration, or the number of waves it sends out per second, be n. Let S′ be its position one second later, its velocity being u. Let R be the receiver at a given instant, R′ its position a second later, its velocity being v. Let the velocity of the air from S to R be w, and let U be the velocity of sound in still air.

FIG. 20.

If all were still, the n waves emitted by S in one second would spread over a length U. But through the wind velocity the first wave is carried to a distance $U + w$ from S, while through the motion of the source the last wave is a distance u from S. Then the n waves occupy a space $U + w - u$. Now turning to the receiver, let us consider what length is occupied by the waves which pass him in one second. If he were at rest, it would be the waves in length $U + w$, for the wave passing him at the beginning of a second would be so far distant at the end of the second. But through his motion v in the second, he receives only the waves in distance $U + w - v$. Since there are n waves in distance $U + w - u$ the number he actually receives is $n(U + w - v)/(U + w - u)$. If the velocities of source and receiver are equal then the frequency is not affected by their motion or by the wind. But if their velocities are different, the frequency of the waves received is affected both by these velocities and by that of the wind.

The change in pitch through motion of the source may be illustrated by putting a pitch-pipe in one end of a few feet of rubber tubing and blowing through the other end while the tubing is whirled round the head. An observer in the plane of the motion can easily hear a change in the pitch as the pitch-pipe moves to and from him.

Musical Quality or Timbre.—Though a musical note has definite pitch or frequency, notes of the same pitch emitted by different instruments have quite different quality or timbre. The three characteristics of a longitudinal periodic disturbance are its amplitude, the length after which it repeats itself, and its form, which may be represented by the shape of the displacement curve. Now the amplitude evidently corresponds to the loudness, and the length of period corresponds to the pitch or frequency. Hence we must put down the quality or timbre as depending on the form.

The simplest form of wave, so far as our sensation goes—that is, the one giving rise to a pure tone—is, we have every reason to suppose, one in which the displacement is represented by a harmonic curve or a curve of sines, $y=a \sin m(x-e)$. If we put this in the form $y=a \sin \frac{2\pi}{\lambda}(x-e)$, we see that $y=0$, for $x=e$, $e+\frac{1}{2}\lambda$, $e+\frac{2}{2}\lambda$, $e+\frac{3}{2}\lambda$, and so on, that y is $+$ from $x=e$ to $x=e+\frac{1}{2}\lambda$, $-$from $e+\frac{1}{2}\lambda$ to $e+\frac{2}{2}\lambda$, and so on, and that it alternates between the values $+a$ and $-a$.

The form of the curve is evidently as represented in fig. 21, and it may easily be drawn to exact scale from a table of sines.

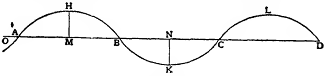

FIG. 21.

In this curve ABCD are nodes. $OA=e$ is termed the epoch, being the distance from O of the first ascending node. AC is the shortest distance after which the curve begins to repeat itself; this length λ is termed the wave-length. The maximum height of the curve $HM=a$ is the amplitude. If we transfer O to A, $e=0$, and the curve may be represented by $y=a \sin \frac{2\pi}{\lambda}x$.

If now the curve moves along unchanged in form in the direction ABC with uniform velocity U, the epoch $e=OA$ at any time t will be Ut, so that the value of y may be represented as

$$y=a \sin \frac{2\pi}{\lambda}(x-Ut). \qquad (16)$$

The velocity perpendicular to the axis of any point on the curve at a fixed distance x from O is

$$\frac{dy}{dt}=-\frac{2\pi Ua}{\lambda}\cos\frac{2\pi}{\lambda}(x-Ut). \qquad (17)$$

The acceleration perpendicular to the axis is

$$\frac{d^2y}{dt^2}=-\frac{4\pi^2U^2a}{\lambda^2}\sin\frac{2\pi}{\lambda}(x-Ut)$$

$$=-\frac{4\pi^2U^2}{\lambda^2}y \qquad (18)$$

which is an equation characteristic of simple harmonic motion.

The maximum velocity of a particle in the wave-train is the amplitude of dy/dt. It is, therefore,

$$u_m=2\pi Ua/\lambda=2\pi na. \qquad (19)$$

The maximum pressure excess is the amplitude of $\hat{\omega}=Eu/U=(E/U)dy/dt$. It is therefore

$$\hat{\omega}_m=(E/U)2\pi Ua/\lambda=2\pi n\rho Ua. \qquad (20)$$

We have already found the energy density in the train and the energy stream in equations (13) and (14).

The chief experimental basis for supposing that a train of longitudinal waves with displacement curve of this kind arouses the sensation of a pure tone is that the more nearly a source is made to vibrate with a single simple harmonic motion, and therefore, presumably, the more nearly it sends out such a harmonic train, the more nearly does the note heard approximate to a single pure tone.

Any periodic curve may be resolved into sine or harmonic curves by Fourier's theorem.

Fourier's Theorem.

Suppose that any periodic sound disturbance, consisting of plane waves, is being propagated in the direction ABCD (fig. 22). Let it be represented by a displacement curve AHBKC. Its periodicity implies that after a certain distance the displacement curve exactly repeats itself. Let AC be the

FIG. 22.

shortest distance after which the repetition occurs, so that CLDME is merely AHBKC moved on a distance AC. Then $AC=\lambda$ is the wave-length or period of the curve. Let ABCD be drawn at such level that the areas above and below it are equal; then ABCD is the axis of the curve. Since the curve represents a longitudinal disturbance in air it is always continuous, at a finite distance from the axis, and with only one ordinate for each abscissa.

Fourier's theorem asserts that such a curve may be built up by the superposition, or addition of ordinates, of a series of sine curves of wave-lengths λ, $\frac{1}{2}\lambda$, $\frac{1}{3}\lambda$, $\frac{1}{4}\lambda$... if the amplitudes a, b, c...and the epochs e, f, g.... are suitably adjusted, and the proof of the theorem gives rules for finding these quantities when the original curve is known. We may therefore put

$$y=a \sin \frac{2\pi}{\lambda}(x-e)+b \sin \frac{4\pi}{\lambda}(x-f)+c \sin \frac{6\pi}{\lambda}(x-g)+\&c. \quad (21)$$

where the terms may be infinite in number, but always have wave-lengths submultiples of the original or fundamental wave-length λ. Only one such resolution of a given periodic curve is possible, and each of the constituents repeats itself not only after a distance equal to its own wave-length λ/n, but evidently also after a distance equal to the fundamental wave-length λ. The successive terms of (21) are called the *harmonics of the first term*.

It follows from this that any periodic disturbance in air can be resolved into a definite series of simple harmonic disturbances of wave-lengths equal to the original wave-length and its successive submultiples, and each of these would separately give the sensation of a pure tone. If the series were complete we should have terms which separately would correspond to the fundamental, its octave, its twelfth, its double octave, and so on. Now we can see that two notes of the same pitch, but of different quality, or different form of displacement curve, will, when thus analysed, break up into a series having the same harmonic wave-lengths; but they may differ as regards the members of the series present and their amplitudes and epochs. We may regard quality, then, as determined by the members of the harmonic series present and their amplitudes and epochs. It may, however, be stated here that certain experiments of Helmholtz appear to show that the epoch of the harmonics has not much effect on the quality.

Fourier's theorem can also be usefully applied to the disturbance of a source of sound under certain conditions. The nature of these conditions will be best realized by considering the case of a stretched string. It is shown below how the vibrations of a string may be deduced from stationary waves. Let us here suppose that the string AB is displaced into the form AHB (fig. 23) and is then let go. Let

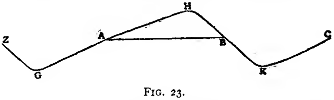

FIG. 23.

us imagine it to form half a wave-length of the extended train ZGAHBKC, on an indefinitely extended stretched string, the values of y at equal distances from A (or from B) being equal and opposite. Then, as we shall prove later, the vibrations of the string may be represented by the travelling of two trains in opposite directions each with velocity

$$\sqrt{\text{tension} \div \text{mass per unit length}}$$

each half the height of the train represented in fig. 23. For the superposition of these trains will give a stationary wave between A and B. Now we may resolve these trains by Fourier's theorem into harmonics of wave-lengths λ, $\frac{1}{2}\lambda$, $\frac{1}{3}\lambda$, &c., where $\lambda=2AB$ and the conditions as to the values of y can be shown to require that the harmonics shall all have nodes, coinciding with the nodes of the fundamental curve. Since the velocity is the same for all disturbances they all travel at the same speed, and the two trains will always remain of the same form. If then we resolve AHBKC into harmonics by Fourier's theorem, we may follow the motion of the separate harmonics, and their superposition will give the form of the string at any instant. Further, the same harmonics with the same amplitude will always be present.

We see, then, that the conditions for the application of Fourier's theorem are equivalent to saying that all disturbances will travel along the system with the same velocity. In many vibrating systems this does not hold, and then Fourier's theorem is no longer an appropriate resolution. But where it is appropriate, the disturbance sent out into the air contains the same harmonic series as the source.

Resonators. The question now arises whether the sensation produced by a periodic disturbance can be analysed in correspondence with this geometrical analysis. Using the term "note" for the sound produced by a periodic disturbance, there is no doubt that a well-trained ear can resolve a note into pure tones of frequencies equal to those of the fundamental and its harmonics. If, for instance, a note is struck and held down on a piano, a little practice enables us to hear both the octave and the twelfth with the fundamental, especially if we have previously directed our attention to these tones by sounding them. But the harmonics are most readily heard if we fortify the ear by an air cavity with a natural period equal to that of the harmonic to be sought. The form used by Helmholtz is a glove of thin brass (fig. 24) with a large hole at one end of a diameter, at the other end of which the brass is drawn out into a short, narrow tube that can be put close to the ear. But a cardboard tube closed at one end, with the open end near the ear, will often suffice, and it may be tuned by more or less covering up the open end. If the harmonic corresponding to the resonator is present its tone swells out loudly.

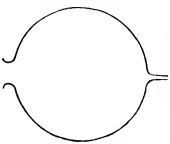

FIG. 24.—Helmholtz Resonator.

Forced Vibration and Resonance. This resonance is a particular example of the general principle that a vibrating system will be set in vibration by any periodic force applied to it, and ultimately in the period of the force, its own natural vibrations gradually dying down. Vibrations thus excited are termed *forced vibrations*, and their amplitude is greater the more nearly the period of the applied force approaches that of the system when vibrating freely. The mathematical investigation of forced vibrations (Rayleigh, *Sound*, i. § 46) shows that, if there were no dissipation of energy, the vibration would increase indefinitely when the periods coincided. But there is always leakage of energy either through friction or through wave-emission, so that the vibration only increases up to the point at which the leakage of energy balances the energy put in by the applied force. Further, the greater the dissipation of energy the less is the prominence of the amplitude of vibration for exact coincidence over the amplitude when the periods are not quite the same, though it is still the greatest for coincidence.

The principle of forced vibration may be illustrated by a simple case. Suppose that a mass M is controlled by some sort of spring, so that moving freely it executes harmonic vibrations given by $M\ddot{x}=-\mu x$, where μx is the restoring force to the centre of vibration. Putting $\mu/M=n^2$ the equation becomes $\ddot{x}+n^2x=0$, whence $x=A\sin nt$, and the period is $2\pi/n$.

Now suppose that in addition to the internal force represented by $-\mu x$, an external harmonic force of period $2\pi/p$ is applied. Representing it by $-P\sin pt$, the equation of motion is now

$$\ddot{x}+n^2x+\frac{P}{M}\sin pt=0. \qquad (22)$$

Let us assume that the body makes vibrations in the new period $2\pi p$, and let us put $x=B\sin pt$; substituting in (22) we have $-p^2B+n^2B+P/M=0$, whence

$$B=\frac{P}{M}\cdot\frac{1}{p^2-n^2},$$

and the "forced" oscillation due to $-P\sin pt$ is

$$x=\frac{P}{M}\cdot\frac{\sin pt}{p^2-n^2}. \qquad (23)$$

If $p>n$ the motion agrees in phase with that which the applied force alone would produce, obtained by putting $n=0$. If $p<n$ the phases are opposite. If $p=n$ the amplitude becomes infinite. This is the case of "resonance." The amplitude does not, of course, become infinite in practice. There is always loss of energy by dissipation in the vibrating machinery and by radiation into the medium, and the amplitude only increases until this loss is balanced by the gain from the work done by the applied force.

The Ear as a Fourier Analyser. According to Helmholtz, the ear probably contains within it a series of resonators, with small intervals between the periods of the successive members, while the series extends over the whole range of audible pitch. We need not here enter into the question of the structure constituting these resonators. Each of them is supposed to have its own natural frequency, and to be set into vibration when the ear receives a train of waves of that frequency. The vibration in some way arouses the sensation of the corresponding tone. But the same resonator will be appreciably though less affected by waves of frequency differing slightly from its own. Thus Helmholtz from certain observations (*Sound*, ii. § 388) thought that if the intensity of response by a given resonator in the ear to its own tone is taken as 1, then its response to an equally loud tone a semitone different may be taken as about $\frac{1}{10}$. According to this theory, then, when a pure tone is received the auditory apparatus corresponding to that tone is most excited, but the apparatus on each side of it is also excited, though by a rapidly diminishing amount, as the interval increases. If the sensations corresponding to these neighbouring elements are thus aroused, we have no such perception as a pure tone, and what we regard as a pure tone is the mean of a group of sensations. The sensitiveness of the ear in judging of a given tone must then correspond to the accuracy with which it can judge of the mean.

Measurements of Intensity of Sound or Loudness.—Various devices have been successfully employed for making sounds of determinate loudness in order to test the hearing of partially deaf people. But the converse, the measurement of the loudness of a sound not produced at our will, is by no means so easy. If we compare the problem with that of measuring the illumination due to a source of light, we see at once how different it is. In sound sensation we have nothing corresponding to white light. A noise such as the roar due to traffic in a town may correspond physically in that it could probably be resolved into a nearly continuous series of wave-lengths, but psychically it is of no interest. We do not use such noise, but rather seek to avoid it. We certainly do not wish to measure its loudness, and even if we did it might be difficult to fix on any unit of noisiness. Probably we should be driven to a purely physical unit, the stream of energy proceeding in any direction, and if the noise were great enough we might measure it possibly by the pressure against a surface.

The intensity of the stream of energy passing per second through a square centimetre when a given pure tone is sounded is more definite and can be measured. There are two practical methods. In the one, the energy of vibration of the source is measured, and the rate at which that energy decreases is observed. The amount radiated out in the form of sound waves is deduced, and hence the energy of the stream at any distance is known. In the other, the waves produce a measurable effect on a vibrating system of the same frequency, and the amplitude in the waves can be deduced.

Minimum Amplitude of Audible Sounds. The first may be illustrated by Lord Rayleigh's experiments to determine the amplitude of vibration in waves only just audible (*Sound*, ii. § 384). He used two kinds of experiment, but it will be sufficient here to indicate the second. A fork of frequency 256 was used as the source. The energy of this fork with a given amplitude of vibration could be calculated from its dimensions and elasticity, and the amplitude was observed by measuring with a microscope the line into which the image of a starch grain on the prong was drawn by the vibration. The rate of loss of energy was calculated from the rate of dying down of the vibration. This rate of loss for each amplitude was determined (1) when the fork was vibrating alone, and (2) when a resonator was placed with its mouth under the free ends of the fork. The difference in loss in the two cases measured the energy given up to and sent out by the resonator as sound. The amplitude of the fork was observed when the sound just ceased to be audible at 27·4 metres away, and the rate of energy emission from the resonator was calculated to be 42·1 ergs / second. Assuming this energy to be propagated in hemispherical waves, it is easy to find the quantity per second going through 1 sq. cm. at the distance of the listener, and thence from the energy in a wave, found above, to determine the amplitude. The result was an amplitude of $1{\cdot}27\times10^{-7}$ cm. Other forks gave results not very different.

In a later series of experiments Lord Rayleigh (*Phil. Mag.*, 1907, 14, p. 596) found that the least energy stream required to excite sensation did not vary greatly between frequencies of 512 and 256, but that the stream required increased rapidly as the frequency was reduced below 256.

The second method may be illustrated by the experiments of M. Wien (*Wied. Ann.*, 1889, xxxvi. 834). He used a spherical Helmholtz resonator resounding to the tone to be measured. The orifice which is usually placed to the ear was enlarged and closed by a corrugated plate like that of an aneroid barometer, and the motion of this plate was indicated by means of a mirror which had one edge fixed, while the other was attached to a style fixed to the centre of the plate. When the plate vibrated the mirror was vibrated about the fixed edge, and the image of a reflected slit was broadened out into a band, the broadening giving the amplitude of vibration of the plate. From subsidiary experiments (for which the original memoir must be consulted) the pressure variations within the resonator could be calculated from the movements of the plate. The open orifice of the resonator was then exposed to the waves from a source of its own frequency. Helmholtz's theory of the resonator (Rayleigh, *Sound*, ii. § 311) gives the pressure variations in the incident waves in terms of those in the resonator, and so the pressure variation and the amplitude of vibration in the waves to be measured were determined.

For minimum audible sounds Wien found a somewhat smaller value of the amplitude than Rayleigh. It is remarkable that, as Lord Rayleigh says, "the streams of energy required to influence the eye and the ear are of the same order of magnitude." Wien also used the apparatus to find the decrease of intensity with increase of distance, and found that it was somewhat more rapid than the inverse square law would give.

In a later series of experiments (*Science Abst.* vi. 301) Wien used a telephone plate, of which the amplitude could be determined from the value of the exciting current, and he found that the smallest amplitude audible was $6 \cdot 3 \times 10^{-10}$ cm.

W. Zernov (*Ann. d. Physik*, 1906, 21, p. 131) compared the indications of Wien's resonator manometer with those of V. Altberg's sound pressure apparatus and found very satisfactory agreement.

Stationary Waves.—As a preliminary to the investigation of the modes of vibration of certain sources of sound we shall consider the formation of "stationary waves." These are not really waves in the ordinary sense, but the disturbance arising from the passage through the medium in opposite directions of two equal trains. The medium is divided up into sections between fixed points, and these sections vibrate. We can form stationary waves with ease by fixing one end of a rope—say 20 ft. long—and holding the other end in the hand. When the hand is moved to and fro *transversely* waves are sent along the rope and reflected at the fixed end. The direct and reflected systems are practically equal, and by suitably timing the vibrations of the hand for each case the rope may be made to vibrate as a whole, as two halves, as three-thirds and so on. When it vibrates in several sections, each section moves in the opposite way to its neighbours.

Let us suppose that two trains of sine waves of length λ and amplitude a are travelling in opposite directions with velocity U. We may represent the displacement due to one of the trains by

$$y_1 = a \sin \frac{2\pi}{\lambda}(x - Ut). \qquad (24)$$

where x is measured as in equation (16) from an ascending node as A in fig. 21. If we measure t from an instant at which the two trains exactly coincide, then as U for the other train has the opposite sign, its displacement is represented by

$$y_2 = a \sin \frac{2\pi}{\lambda}(x + Ut). \qquad (25)$$

The sum of the disturbance is obtained by adding (24) and (25)

$$y = y_1 + y_2 = 2a \cos \frac{2\pi}{\lambda}Ut \sin \frac{2\pi}{\lambda}x, \qquad (26)$$

At any given instant t this is a sine curve of amplitude $2a \cos (2\pi/\lambda)Ut$, and of wave-length λ, and with nodes at $x = 0, \frac{1}{2}\lambda, \lambda, \ldots$, that is, there is no displacement at these nodes whatever the value of t, and between them the displacement is always a sine curve, but of amplitude varying between $+2a$ and $-2a$. The ordinate of the curve changes sign as we pass through a node, so that successive sections are moving always in opposite directions and have opposite displacements. Each section then vibrates, and its amplitude goes through all its values in time given by $2\pi UT/\lambda = 2\pi$, or $T = \lambda/U$, and the frequency is U/λ. We may represent such a train of "stationary waves" by fig. 25, where the curves give the

FIG. 25.

two extreme amplitudes. The points A, B, C, D are termed "nodes," and the points half-way between them "loops."

The general character of these results may be obtained by a graphic construction. Let fig. 26 (1) represent a wave-length of each train when they are coincident. It is sufficient to take a single wave-length. The dotted curve represents the superposition, which simply doubles each ordinate. Divide the wave-length into, say, eight equal parts as marked. Then move one train marked (I) $\frac{1}{8}\lambda$ to the right, and the other train (II) $\frac{1}{8}\lambda$ to the left, introducing new parts of each train at one end, and sending out old parts at the other. Then we get fig. 26 (2), the dotted curve representing

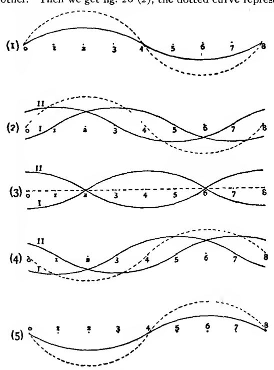

FIG. 26.

the resultant with amplitude $1/\sqrt{2}$ that of (1). Another movement of $\frac{1}{4}\lambda$ in each direction gives (3) with resultant a straight line, and so on for (4) and (5). In (5) the displacement is evidently equal and opposite to that in (1). Further displacement will give the figures (4), (3), (2), (1) again, but with (I) and (II) interchanged. When we get back to (1) each train has been displaced through λ and the period is λ/U. Further, the original nodes are always at rest, and the intervening sections vibrate to and fro.

The vibrations of certain sources of sound may be represented, at least as a first approximation, as consisting of stationary waves, and from a consideration of the rate of propagation of waves along these sources we can deduce their frequency when we know their length.

Sources of Sound.

Elementary Theory of Pipes.—The longitudinal vibration of air in cylindrical pipes is made use of in various wind instruments. We shall deduce the modes of vibration of the air column in a cylindrical pipe from the consideration that the air in motion within the pipe forms some part of a system of stationary waves, one train being formed by the exciter of the disturbance, and the other being formed by the reflection of the train at the end of the pipe.

In order to justify the use of stationary waves we must show that two such trains can move in opposite directions over the same ground without modifying each other so long as the displacement in either is small. For this it is necessary that the total force on an element due to the sum of the displacements should be equal to the sum of the forces due to the two displacements considered separately. The medium then acts for the second train just as if it were undisturbed by the first. It is sufficient then to show that the excess of pressure at any point is the sum of the excesses due to either train separately.

If ω is the total pressure excess, and if y is the total displacement at x, then $\omega = E \times$change of volume ÷ original volume $= -E dy/dx$. If y_1 and y_2 are the two separate displacements and if $y = y_1 + y_2$, then $\omega = -E\,(dy_1/dx + dy_2/dx) = \omega_1 + \omega_2$. This proves the proposition. It is a case of the principle of superposition of small disturbances.

Let us suppose that a system of stationary waves is formed in the air in a pipe of indefinite length, and let fig. 27 represent a part of the system. At the nodes A, B, C, D, E there is no displacement, but there are maximum volume and pressure changes. Consider, for instance, the point B. When the displacement is represented by AHBKC the particles on each side of B are displaced towards it giving a compression, and since the slope is steepest there, or $-dy/dx$ a maximum, the compression is also a maximum there. When the displacement is represented by AH′BK′C the particles on each side of B are displaced from it, giving an extension, and since the slope is again the steepest, the extension is a maximum.

FIG. 27.

At the loops, for instance at H, the displacement is a maximum. The tangent to the displacement curve is always parallel to the axis, that is, for a small distance the successive particles are always equally displaced, and therefore always occupy the same volume. This means that at the loops while the motion is greatest there are no pressure changes.

We have now to select such portion of this system as will suit the conditions imposed by any actual pipe. There are three distinct types, which we will consider in succession.

1. *Pipe Closed at One End, Open at the Other.*—At the closed end there is no motion, for the pressure always constrains the air to remain in contact with the end. The closed end is therefore a node. At the open end, as a first approximation to be corrected later, there are no pressure changes, for any tendency to excess can be relieved by immediate expansion into the outer air, and any tendency to defect can be filled up by an inrush from the outer air. The open end is therefore a loop. It is to be noted that the exciter of the vibrations is in general at the open end, and that the two trains forming the stationary system consist of the direct waves from the exciter travelling into the tube, and the waves reflected back from the closed end.

In fig. 27 we may have the length AH occupying the tube. In this case $AH=\frac{1}{4}\lambda_1=l$, the length of the tube, and the frequency $n_1=U/\lambda_1=U/4l$. But we may also have a shorter wave-length λ_2 such that the length AK occupies the tube. In this case $AK=\frac{3}{4}\lambda_2=l$, and the frequency $n_2=U/\lambda_2=3U/4l$. With a still shorter wave-length λ_3 we may have the length AL occupying the tube and $AL=\frac{5}{4}\lambda_3=l$, and the frequency $n_3=U/\lambda_3=5U/4l$, and so on, as we take succeeding loops for the open end.

In fig. 28 are represented the stationary wave systems of the first four modes, and any of the succeeding ones are easily drawn.

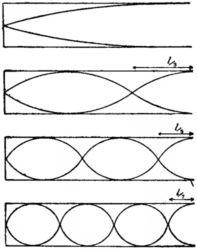

FIG. 28.

The reader will be able to make out the simultaneous motions and pressures at various points. It is obvious that the nodes are alternately in compression and extension, or vice versa, and that for $\frac{1}{4}\lambda$ on each side of a node the motion is either to it on both sides or from it on both sides.

The first mode of vibration gives the "fundamental tone," and the succeeding modes are termed "overtones." The whole series forms the series of odd harmonics. A "stopped pipe" in an organ is a pipe of this type, and both the fundamental and the overtones may occur simultaneously when it is blown.

We may illustrate the successive modes of vibration by using as pipe a tall cylindrical jar, and as exciter a vibrating tuning-fork held over the mouth. The length of the pipe may be varied by pouring in water, and this is done until we get maximum resonance of the pipe to the fork. Thus if a fork $Ut_3=256$ is used, the length of pipe for the fundamental at 0° C. is about $33{,}000/4\times256=33$ cms. If a fork $Sol_4=768$ is used the pipe resounds to it according to the mode of the first overtone. If the temperature is t^0 the length for given frequency must be increased by the factor $1+0{\cdot}00184t$.

Correction to Length at the Open End.—The approximate theory of pipes due to Bernoulli assumes a loop at the open end, but the condition for a loop at the open end, that of no pressure variation, cannot be exactly fulfilled. This would require that the air outside should have no mass in order that it should at once move out and relieve the air at the end of the pipe from any excess of pressure, or at once move in and fill up any defect. There are variations, therefore, at the open end, and these are such that the loop may be regarded as situated a short distance outside the end of the pipe. It may be noted that in practice there is another reason for pressure variation at the end of the pipe. The stationary wave method regards the vibration in the pipe as due to a series of waves travelling to the end and being there reflected back down the pipe. But the reflection is not complete, for some of the energy comes out as waves; hence the direct and reflected trains are quite equal, and cannot neutralize each other at the loop.

The position of the loop has not yet been calculated for an ordinary open pipe, but Lord Rayleigh has shown (*Sound*, ii. § 307) that for a cylindrical tube of radius R, provided with a flat extended flange, the loop may be regarded as about 0·82 R, in advance of the end. That is, the length of the pipe must be increased by 0·82 R before applying Bernoulli's theory. This is termed the "end correction."

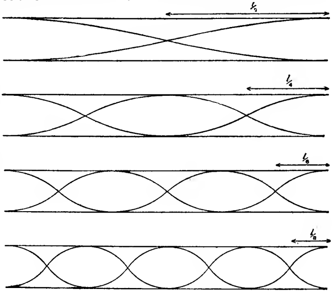

FIG. 29.

Using this result Rayleigh found the correction for an unflanged open end by sounding two pipes nearly in unison, each provided with a flange, and counting the beats. Then the flange was removed from one and the beats were again counted. The change in virtual length by removal of the flange was thus found, and the open end correction for the unflanged pipe was 0·6 R. This correction has also been found by David James Blaikley by direct experiment (*Phil. Mag.*, 1879, 7, p. 339). He used a tube of variable length and determined the length resounding to a given fork, (1) when the closed end was the first node, (2) when it was the second node. If these lengths are l_1 and l_2, then $l_2-l_1=\frac{1}{2}\lambda$ and $\frac{1}{2}(l_2-l_1)-l_1$ is the correction for the open end. The mean value found was 0·576 R.

2. *Pipe Open at Both Ends.*—Each end is a loop. We must therefore select a length of fig. 27 between two loops. The fundamental mode is that in which H and K represent the ends of the pipe. In this case $HK=\frac{1}{2}\lambda_1=l$, and the frequency is $n_1=U/\lambda_1=U/2l$. There is a node in the middle. In the next mode H and L represent the ends and $HL=\lambda_2=l$ and $n_2=U/\lambda_2=2U/2l$. In the third mode $HM=\frac{3}{2}\lambda_3=l$ and $n_3=U/\lambda_3=3U/2l$, and so on.

In fig. 29 are represented the stationary wave systems of the first four modes. The whole series of fundamental and overtones gives the complete set of harmonics of frequencies proportional to 1, 2, 3, 4, . . . , and wave-lengths proportional to 1, $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$. . . .

A metal or brass tube will serve as such a pipe, and may be excited by a suitable tuning-fork held at one end. To obtain the virtual length we must add the correction for each open end, probably about 1·2 radius. If the frequency is 256 the corrected length for the fundamental is about $(33{,}000/2\times256)\ (1+{\cdot}00184t)$ at t^0. The pipe will also resound to forks of frequencies 512, 768, 1024 and so on.

An open "flue" organ pipe is of this type. The wind rushing through the slit S (fig. 30) maintains the vibration in a way to be discussed later, and the opening O makes the lower end a loop.

The modes of vibration in an open organ pipe may be exhibited by means of Koenig's manometric flames (*Phil. Mag.*, 1873, vol. 45). The pipe is provided with manometric flames at its middle point, and at one-quarter and three-quarters of its length. When the pipe is blown softly the fundamental is very predominant, and there is a node at the middle point. The flame there is much affected by the nodal pressure changes, while the other two vibrate only slightly. If, however, the pipe is blown strongly, the fundamental dies away, and the first overtone is predominant. Then the middle point is a loop, and the middle flame is only slightly affected, while the other two, now being at nodes, vibrate strongly.

FIG. 30.

3. *Pipe Closed at Both Ends.*—The two ends in such a pipe are nodes. It is evident that the overtones will follow the same rule as for a pipe opened at both ends. This case is not exactly realized in practice, but it is closely approximated to in *Kundt's dust-tube.* A glass tube, the "dust-tube," 3 ft. or more in length, and perhaps 1 in. in diameter, has a little lycopodium powder introduced, and the powder is allowed to run all along the tube, which is then fixed horizontally. A closely-fitting adjustable piston is provided at one end. A glass or metal rod, the "sounder," is clamped at its middle point, and fixed along the prolongation of the axis of the dust-tube as in fig. 31, a loosely-fitting cork or card piston being fixed on one end of the sounder, which is inserted within the dust-tube. The other end of the sounder is stroked outwards with a damp cloth so as to make it sound its fundamental. Stationary waves are formed in the air in the dust-tube if the length is rightly adjusted by the closely-fitting piston, and the lycopodium dust collects at the nodes in little heaps, the first being at the fixed end and the last just in front of the piston on the sounder. The stationary wave system adjusts itself so that its motion agrees with that of the sounder, which is therefore not exactly at a node. If U_s is the velocity of longitudinal waves along the sounder, and l the length of the sounder, the frequency of vibration is $U_s/2l$. If L is the distance between successive dust-heaps, *i.e.* half a wave-length, the frequency in the air is U/2L, where U is the velocity of sound in the pipe. Then, since the frequencies are the same, $U/2L=U_s/2l$ or $L/l=U/U_s$.

FIG. 31.

The velocities in different gases may be compared by this apparatus by filling the dust-tube with the gases in place of air. If L_1 is the internodal distance and U_1 the velocity in a gas, L and U being the corresponding values for air, we have $U_1/U=L_1/L$.

Kundt's dust-tube may also be employed for the determination of the ratio of the specific heats of a gas or vapour. If U is the velocity of sound in a gas at pressure P with density ρ, and if waves of length λ and frequency N are propagated through it, then the distance between the dust-heaps is

Specific Heats' Ratio.

$$d=\frac{\lambda}{2}=\frac{U}{2N}=\frac{1}{2N}\sqrt{\frac{\gamma P}{\rho}},$$

where γ is the ratio of the two specific heats. If d is measured for two gases in succession for the same frequency N, we have

$$\frac{\gamma_2}{\gamma_1}=\frac{\rho_2 P_1}{\rho_1 P_2}\frac{d_2^2}{d_1^2},$$

where the suffixes denote the gases to which the quantities relate. If γ_1 is known this gives γ_2. Kundt and Warburg applied the method to find γ for mercury vapour (*Pogg. Ann.*, 1876, 157, p. 356), using a double form of the apparatus in which there are two dust-tubes worked by the same sounding rod. This rod is supported at $\frac{1}{4}$ and $\frac{3}{4}$ of its length where it enters the two dust-tubes, as represented diagrammatically in fig. 32. It is stroked in the middle so as to

FIG. 32.

excite its second mode of vibration. The method ensures that the two frequencies shall be exactly the same. In the mercury experiment the sounding rod was sealed into the dust-tube, which was exhausted of air, and contained only some mercury and some quartz dust to give the heaps. It was placed in a high temperature oven, where the mercury was evaporated. The second tube containing air was outside. When a known temperature was attained the sounder was excited, and d_2 and d_1 could be measured. From the temperature, P_2/ρ_2 was known, and γ_2/γ_1 could then be found. Taking $\gamma_1=1{\cdot}41$, γ_2 was determined to be 1·66. Lord Rayleigh and Sir William Ramsay (*Phil. Trans.* A. 1895, pt. i. p. 187) also used a single dust-tube with a sounder to find γ for argon, and again the value was 1·66.

Determinations of Pressure Changes and Amplitude of Vibrations in Pipes.—If the maximum pressure change is determined, the amplitude is given by equation (20), viz.

$$\hat{\omega}_m=2\pi n a\rho U,$$

for in the stationary wave system the pressure change and the amplitude are both double those in either train, so that the same relation holds.

Determinations of the pressure changes, or extent of excursion of the air, in sounding organ pipes have been made by A. Kundt (*Pogg. Ann.*, 1868, 134, p. 163), A. J. I. Töpler and L. Boltzmann (*Pogg. Ann.*, vol. 141, or Rayleigh, *Sound*, ii. § 422*a*), and E. Mach (*Optisch-akustischen Versuche*, 1873). Mach's method is perhaps the most direct. The pipe was fixed in a horizontal position, and along the top wall ran a platinum wire wetted with sulphuric acid. When the wire was heated by an electric current a fine line of vapour descended from each drop. The pipe was closed at the centre by a membrane which prevented a through draught, yet permitted the vibrations, as it was at a node. The vapour line, therefore, merely vibrated to and fro when the pipe was sounded. The extent of vibration at different parts of the pipe was studied through a glass side wall, a stroboscopic method being used to get the position of the vapour line at a definite part of the vibration. Mach found an excursion of 0·4 cm. at the end of an open pipe 123 cm. long. The amplitude found by the other observers was of the same order. For the vibration of air in other cavities than long cylindrical pipes we refer to Rayleigh's *Sound*, vol. ii. chs. 12 and 16.

Amplitude of Vibration.

Propagation of Waves in Pipes of Circular Section.—Helmholtz investigated the velocity of propagation of sound in pipes, taking into account the viscosity of the air (Rayleigh, *Sound*, ii. § 347), and Kirchhoff investigated it, taking into account both the viscosity and the heat communication between the air and the walls of the pipe (*loc. cit.* ii. § 350). Both obtained the value for the velocity

$$U\left(1-\frac{C}{R\sqrt{2\pi N\rho}}\right),$$

where U is the velocity in free air, R is the radius of the pipe, N the frequency, and ρ the air density. C is a constant, equal to the coefficient of viscosity in Helmholtz's theory, but less simple in Kirchhoff's theory. Experiments on the velocity in pipes were carried out by H. Schneebeli (*Pogg. Ann.*, 1869, 136, p. 296) and by T. J. Seebeck (*Pogg. Ann.*, 1870, 139, p. 104) which accorded with this result as far as R is concerned, but the diminution of velocity was found to be more nearly proportional to $N^{-\frac{3}{4}}$. Kundt also obtained results in general agreement with the formula (Rayleigh, *Sound*, ii. § 260). He used his dust-tube method.

Elementary Theory of the Transverse Vibration of Musical Strings.

We shall first investigate the velocity with which a disturbance travels along a string of mass m per unit length when it is stretched with a constant tension T, the same at all points. We shall then show that on certain limitations two trains of disturbance may be superposed so that stationary waves may be formed, and thence we shall deduce the modes of vibration as with pipes.

FIG. 33.

Let AB (fig. 33) represent the string with the ends AB fixed. Let a disturbance once set going travel along unchanged in form from A to B with velocity U. Then move AB from right to left with this velocity, and the disturbance remains fixed in space. Take a point P in the disturbed part, and a point Q which the disturbance has not yet reached. Since the conditions in the region PQ remain always the same, the momentum perpendicular to AB entering the region at Q is equal to the momentum perpendicular to AB leaving the region at P. But, since the motion at Q is along AB, there is no momentum there perpendicular to AB. So also there is on the whole none in that direction leaving at P. Let the tangent at P make angle ϕ with AB. The velocity of the string at P parallel to PM is U sin ϕ, and the mass of string passing P is mU per second, so that $mU^2 \sin\phi$ is carried out per second. But the tension at P is T, parallel to the tangent, and T sin ϕ parallel to PM, and through this $-T\sin\phi$ is the momentum passing out at P per second. Since the resultant is zero, $mU^2\sin\phi-T\sin\phi=0$, or $U^2=T/m$.

Now keep AB fixed, and the disturbance travels with velocity U. We might make this investigation more general by introducing a force X as in the investigation for air, but it hardly appears necessary.

To form stationary waves two equal trains must be able to travel in opposite directions with equal velocities, and to be superposed. We must show then that the force called out by the sum of the disturbances is equal to the sum of the forces called out by each train separately.

In order that the velocity shall remain unchanged the tension T must remain the same. This implies that the disturbance is so small that the length is not appreciably altered. The component of T acting parallel to the axis or straight string is $\mathrm{T}dx/ds$, and when the disturbance is sufficiently small the curve of displacement is so nearly parallel to the axis that $dx/ds = 1$, and this component is T. The component of T perpendicular to the axis is $\mathrm{T}dy/ds = \mathrm{T}dy/dx$. Now if y_1 and y_2 are the displacements due to the two trains separately, and $y = y_1 + y_2$, the two separate forces are $\mathrm{T}dy_1/dx$ and $\mathrm{T}dy_2/dx$, while that due to y is $\mathrm{T}dy/dx$. But since $y = y_1 + y_2$, $\mathrm{T}dy/dx = \mathrm{T}dy_1/dx + \mathrm{T}dy_2/dx$, or the condition for superposition holds when the displacement is so small that we may put $dx/ds = 1$. Evidently this comes to neglecting ϕ^3. Let two trains of equal waves moving in opposite directions along such a string of indefinite length form the stationary system of fig. 27. Since the nodes are always at rest we may represent the vibration of a given string by the length between any two nodes. The fundamental mode is that in which A and B represent the ends of the string. In this case $\mathrm{AB} = \frac{1}{2}\lambda_1 = l$ the length, and the frequency $n_1 = \mathrm{U}/\lambda_1 = \mathrm{U}/2l = (1/2l)\sqrt{(\mathrm{T}/m)}$. The middle of the string is a loop. In the next mode A and C represent the ends and $\mathrm{AC} = \lambda_2 = l$ and $n_2 = \mathrm{U}/\lambda_2 = 2\mathrm{U}/2l = (2/2l)\sqrt{(\mathrm{T}/m)}$. In the third mode A and D represent the ends and $\mathrm{AD} = \frac{3}{2}\lambda_3 = l$ and $n_3 = \mathrm{U}/\lambda_3 = 3\mathrm{U}/2l = (3/2l)\sqrt{(\mathrm{T}/m)}$ and so on. In fig. 34 the stationary wave systems of the first four modes are represented.

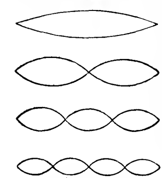

FIG. 34.

The complete series of harmonics are possible modes.

The experimental demonstration of these results is easily made by the sonometer or monochord (fig. 35). A string is fixed at C on the top of a hollow box, and

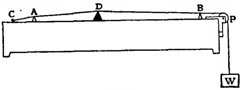

FIG. 35.

passes over two edges AB, which serve as the fixed ends, and then over a pulley P, being stretched by a weight W. Between A and B a "bridge" D, *i.e.* another edge slightly higher than A or B, can be inserted in any position, which is determined by a graduated scale. The effective length of the string is then AD. Keeping the same tension, it may be shown that nl is constant by finding n for various lengths. Keeping AD constant and varying W it may be shown that $n \propto \sqrt{\mathrm{W}}$. Lastly, by using different strings, it may be shown that, with the same T and l, $n \propto \sqrt{(1/m)}$.

The various modes of vibration may also be exhibited. If D is removed and the string is bowed in the middle, the fundamental is brought out. If it is touched in the middle with a feather, the edge of a card, or the finger nail, and bowed a quarter of the way along the octave, the first overtone comes out. Each of the first few harmonics may be easily obtained by touching the string at the first node of the harmonic required, and bowing at the first loop, and the presence of the nodes and loops may be verified by putting light paper riders of shape ∧ on the string at the nodes and loops. When the harmonic is sounded the riders at the loops are thrown off, while those at the nodes remain seated.

Not only may the fundamental and its harmonics be obtained separately, but they are also to be heard simultaneously, particularly the earlier ones, which are usually more prominent than those higher in the series. A practised ear easily discerns the coexistence of these various tones when a pianoforte or violin string is thrown into vibration. It is evident that, in such case, the string, while vibrating as a whole between its fixed extremities, is at the same time executing subsidiary oscillations about its middle point, its points

FIG. 36.

of trisection, &c., as shown in fig. 36, for the fundamental and the first harmonic. When a string is struck or bowed at a point, any harmonic with a node at that point is absent. Since the quality of the note sounded depends on the mixture of harmonics, the quality therefore is to some extent dependent on the point of excitation.

A highly ingenious and instructive method for illustrating the laws of musical strings was contrived by F. E. Melde. It consists in attaching to the loop or ventral segment of a vibrating body, *e.g.* a tuning-fork or a bell-glass, a silk or cotton thread, the other extremity being either fixed or passing over a pulley and supporting weights by which the thread may be stretched to any degree required. The vibrations of the larger mass are communicated to the thread, which by proper adjustment of its length and tension vibrates in unison and divides itself into one or more loops or ventral segments easily discernible by a spectator. If the length of the thread be kept invariable, a certain tension will give but one ventral segment; the fundamental note of the thread is then of the same pitch as the note of the body to which it is attached. By reducing the tension to one quarter of its previous amount, the number of ventral segments will be seen to be increased to two, indicating that the first harmonic of the thread is now in unison with the solid, and consequently that its fundamental is an octave lower than it was with the former tension; thus confirming the law that n varies as $\sqrt{\mathrm{T}}$. In like manner, on further lowering the tension to one ninth, three ventral segments will be formed, and so on.

The law that, *caeteris paribus*, n varies inversely as the thickness may be tested by forming a string of four lengths of the single thread used before, and consequently of double the thickness of the latter, when, for the same length and tension, the compound thread will exhibit double the number of ventral segments presented by the single thread.

The other laws admit of similar illustration.

Longitudinal Vibrations of Wires and Rods.

Subject to a limitation which we shall examine later, the velocity of a longitudinal disturbance along a wire or rod depends only on the material of the rod, and not upon the cross-section. Since the forces called into play by an extension or compression of the material are proportional to the cross-section, it follows that if we consider any case and then another case in which, with the same longitudinal disturbance, the cross-section is doubled, the force in the second case is doubled as well as the mass to be moved. The acceleration therefore remains the same, and the velocity is unaltered. We shall find the velocity of propagation, just as in previous cases, from the consideration of transfer of momentum.

Suppose that a disturbance is travelling with velocity U unchanged in form along a rod from left to right. Let us move the rod from right to left, so that the undisturbed parts move with velocity U. Then the disturbance remains fixed in space. Let A be a point in

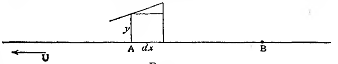

FIG. 37.

the disturbance, and B a point in the undisturbed part. The material between A and B, though continually changing, is always in the same condition, and therefore the momentum within AB is constant. Hence the amount carried out at A is equal to that carried in at B.

Now momentum is transferred in two ways, viz. by the force acting between contiguous portions of a body and by the transfer of moving matter. At B there is only the latter kind, and since the transfer of matter is $\rho_0\bar{\omega}_0\mathrm{U}$, where ρ_0 is the undisturbed density and $\bar{\omega}_0$ is the undisturbed cross-section, since its velocity is U the passage of momentum per second is $\rho_0\bar{\omega}_0\mathrm{U}_0^2$. At A, if the velocity of the disturbance relative to undisturbed parts of the rod is u from left to right, the velocity relative to A is $\mathrm{U} - u$. If ρ is the density at A, and $\bar{\omega}$ the cross-section, then the momentum carried past A is $\rho\bar{\omega}(\mathrm{U} - u)^2$. But if y is the displacement at A, dy/dx is the extension at A, and the force acting is a pull across A equal to $\mathrm{Y}\bar{\omega}_0 dy/dx$, where Y is Young's modulus of elasticity. Then we have

$$\mathrm{Y}\bar{\omega}_0 dy/dx + \rho\bar{\omega}(\mathrm{U} - u)^2 = \rho_0\bar{\omega}_0\mathrm{U}^2. \tag{27}$$

Now

$$u/\mathrm{U} = -dy/dx, \tag{28}$$

for the particle at A moves over dy backwards, while the disturbance moves over U. Also since dx has been stretched to $dx + dy$

$$\rho\bar{\omega}(dx + dy) = \rho_0\bar{\omega}_0 dx$$

or

$$\rho\bar{\omega}(1 + dy/dx) = \rho_0\bar{\omega}_0. \tag{29}$$

Substituting from (28) in (27)

$$\mathrm{Y}\bar{\omega}_0\frac{dy}{dx} + \rho\bar{\omega}\mathrm{U}^2\left(1 + \frac{dy}{dx}\right)^2 = \rho_0\bar{\omega}_0\mathrm{U}^2, \tag{30}$$

and substituting from (29) in (30)

$$\mathrm{Y}\bar{\omega}_0\frac{dy}{dx} + \rho_0\bar{\omega}_0\mathrm{U}^2\left(1 + \frac{dy}{dx}\right) = \rho_0\bar{\omega}_0\mathrm{U}^2, \tag{31}$$

whence

$$\mathrm{Y}\bar{\omega}_0 = \rho_0\bar{\omega}_0\mathrm{U}^2,$$

or

$$\mathrm{U}^2 = \mathrm{Y}/\rho, \tag{32}$$

where now ρ is the normal density of the rod. The velocity with which the rod must travel in order that the disturbance may be fixed in space is therefore $\mathrm{U} = \sqrt{(\mathrm{Y}/\rho)}$, or, if the rod is kept fixed, this is the velocity with which the disturbance travels.

This investigation is subject to the limitation that the diameter of the cross-section must be small compared with the wave-length. When the rod extends or contracts longitudinally it contracts or extends radially and in the ratio σ, known as Poisson's ratio, which in metals is not far from $\frac{1}{4}$. Let us suppose that the rod is circular, of radius r, and that the radial displacement of the surface is η. The longitudinal extension is dy/dx, and therefore the radial contraction is $\eta/r = \sigma dy/dx$. If then $y = a \sin \frac{2\pi}{\lambda}(x - \mathrm{U}t)$, $\eta = \frac{2\pi\sigma r a}{\lambda} \cos \frac{2\pi}{\lambda}(x - \mathrm{U}t)$. If r is of the order of λ, η is of the order of y; and the kinetic energy of the radial motion is of the same order as that of the longitudinal motion. But our investigation entirely leaves this out of account, and is therefore faulty. In fact, the forces are then no longer parallel to the axis. There are shears of the order $d\eta/dx$ and the simple Young's modulus system can no longer be taken to represent the actual condition (see Rayleigh, *Sound*, i. § 157). But keeping r/λ small we may as before form stationary waves, and it is evident that the series of fundamental and overtones will be just as with the air in pipes, and we shall have the same three types—fixed at one end, free at both ends, fixed at both ends—with fundamental frequencies respectively

$$\frac{1}{4l}\sqrt{\frac{\mathrm{Y}}{\rho}},\ \frac{1}{2l}\sqrt{\frac{\mathrm{Y}}{\rho}},\ \text{and}\ \frac{1}{l}\sqrt{\frac{\mathrm{Y}}{\rho}}.$$

The overtones will be obvious.

For an iron wire Y/ρ is about $10^{12}/4$, so that for a frequency of 500 in a wire fixed at both ends a length about 5 metres is required. If the wire is stretched across a room and stroked in the middle with a damp cloth the fundamental is easily obtained, and the first harmonic can be brought out by stroking it at a quarter the length from one end. A glass or brass rod free at both ends may be held by the hand in the middle and excited by stroking one end outwards with a damp cloth. If it is clamped at one-quarter and three-quarters of the length from the ends, and is stroked in the middle, the first harmonic sounds.

Young's modulus may be obtained for the material of a rod by clamping it in the middle and obtaining the frequency of the fundamental when $\mathrm{Y} = 4l^2n^2\rho$.

The value thus obtained is generally appreciably greater than that obtained by a statical method in which the rod is pulled out by an applied tension.

Rods of different materials may be used as sounders in a Kundt's dust tube, and their Young's moduli may be compared, since:—

$$\text{velocity in rod} = \text{velocity in air} \times \frac{\text{length of rod}}{\text{distance between dust-heaps.}}$$

Torsional Vibrations of Rods and Wires.—The velocity of propagation of a torsional disturbance along a wire of circular section may be found by the transfer of momentum method, remembering that we must now replace linear momentum by angular momentum. Let the disturbance be supposed to travel unchanged in form from left to right with velocity U. Now suppose that the wire or rod is moved from right to left with velocity U. The disturbance is then fixed in space. Let A be a point in the disturbance and B a point in the undisturbed portion. The condition of the matter between A and B remains constant, though fresh matter keeps coming in at B and an equal quantity leaves at A. Hence the angular momentum of the part between A and B remains constant, or as much enters at B as leaves at A. But at B there is no torsion, and no torsion couple of one part of the wire on the next. So that no angular momentum enters at B, and therefore on the whole none leaves at A. The transfer of angular momentum through A is of two kinds—first, that due to the passage of rotating matter, and, secondly, that due to the couple with which matter to the right of A acts upon matter to the left of A. The mass of matter moving through A per second is $\rho\pi a^2\mathrm{U}$, where a is the radius of the wire and ρ is its density. If θ is the angle of twist, the angular velocity is $d\theta/dt$. The radius of gyration of the section is $\frac{1}{2}a^2$. Hence the angular momentum conveyed per second outwards is $\frac{1}{2}\rho\pi a^4\mathrm{U}d\theta/dt$. The couple due to the twist of a wire of length l through ϕ is $\mathrm{G} = \frac{1}{2}n\pi a^4\phi/l$, and we may put $\phi/l = d\theta/dx$. Since no angular momentum goes out on the whole

$$\tfrac{1}{2}n\pi a^4 d\theta/dx + \tfrac{1}{2}\rho\pi a^4\mathrm{U}d\theta/dt = 0. \qquad (33)$$

But the condition of unchanged form requires that the matter shall twist through $(d\theta/dx)dx$ while it is travelling over dx, *i.e.* in time dx/U.

Then $$\frac{d\theta}{dt}\ \frac{dx}{\mathrm{U}} = -\frac{d\theta}{dx}dx \text{ or } \frac{d\theta}{dt} = -\mathrm{U}\frac{d\theta}{dx}.$$

Substituting in (33) we get

$$\mathrm{U}^2 = n/\rho. \qquad (34)$$

If we now keep the wire at rest the disturbance travels along it with velocity $\mathrm{U} = \sqrt{(n/\rho)}$, and it depends on the rigidity and density of the wire and not upon its radius.

It is easy to deduce the modes of vibration from stationary waves as in the previous cases. If a rod is clamped at one end and free at the other, the fundamental frequency is $(1/l)\sqrt{(n/\rho)}$. For iron n/ρ is of the order 10^{11}, so that the frequency for a rod 1 metre long is about 3000. When a cart wheel is ungreased it produces a very high note, probably due to torsional vibrations of the axle.

The torsional vibrations of a wire are excited when it is bowed. If small paper rings are put on a monochord wire they rotate through these vibrations when the wire is bowed.

Transverse Vibrations of Bars or Rods.—When a bar or rod is of considerable cross-section, a transversal disturbance calls into play forces due to the strain of the material much more important than the forces due to any tension which is ordinarily applied. The velocity of a disturbance along such a bar, and its modes of vibration, depend therefore on the elastic properties of the material and the dimensions of the bar. We cannot investigate the vibrations in an elementary manner. A full discussion will be found in Rayleigh's *Sound*, vol. i. ch. 8. We shall only give a few results.

The cases interesting in sound are those in which (1) the bar is free at both ends, and (2) it is clamped at one end and free at the other.

For a bar free at both ends the fundamental mode of vibration has two nodes, each 0·224 of the length from the end. The next mode has a node in the middle and two others each 0·132 from the end. The third mode has four nodes 0·094 and 0·357 from each end, and so on. The frequencies are nearly in the ratios $3^2:5^2:7^2$. . . . Such bars are used in the harmonicon.

When one end is clamped and the other is free the clamped end is always a node. The fundamental mode has that node only. The next mode has a second node 0·226 from the free end; the next, nodes at 0·132 and 0·5 from the free end, and so on. The frequencies are nearly in the ratios 1:6·25:17·5. Such bars are used in musical boxes and as free reeds in organ pipes.

The most important example of this type is the tuning-fork, which may be regarded as consisting of two parallel bars clamped together at the base. The first overtone has frequency 6·25 that of the fundamental, and is not in the harmonic series. If the fork be mounted on a resonance box or held in front of a cavity resounding to the fundamental and not to the first overtone, the fundamental is brought out in great purity.

Vibrations of Plates.—These are for the most part interesting rather from the point of view of elasticity than of sound. We shall not attempt to deal with the theory here but shall describe only the beautiful mode of exhibiting the regions of vibration and of rest devised by E. F. F. Chladni (1756–1827). As usually arranged, a thin metal plate is screwed on to the top of a firm upright post at the centre of the plate, which is horizontal. White sand is lightly scattered by a pepper-box over the plate. The plate is then bowed at the edge and is thrown into vibration between nodal lines or curves and the sand is thrown from the moving parts or ventral segments into these lines, forming "Chladni's figures." The development of these figures by a skilful bower is very fascinating. As in the case of a musical string, so here we find that the pitch of the note is higher for a given plate the greater the number of ventral segments into which it is divided; but the converse of this does not hold good, two different notes being obtainable with the same number of such segments, the position of the nodal lines being, however, different.

The upper line of annexed figures shows how the sand arranges itself in three cases, when the plate is square. The lower line gives the same in a sort of *idealized* form. Fig. 38, 1, corresponds to the

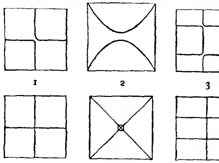

Fig. 38.

lowest possible note of the particular plate used; fig. 38, 2, to the *fifth* higher; fig. 38, 3, to the *tenth* or octave of the *third*, the numbers of vibration in the same time being as 2 to 3 to 5.

If the plate be small, it is sufficient, in order to bring out the simpler sand-figures, to hold the plate firmly between two fingers of the same hand placed at any point where at least two nodal lines meet, for instance the centre in (1) and (2), and to draw a violin bow downwards across the edge near the middle of a ventral segment. But with larger plates, which alone will furnish the more complicated figures, a clamp-screw must be used for fixing the plate, and, at the same time, one or more other nodal points ought to be touched with the fingers while the bow is being applied. In this way, any of the possible configurations may be easily produced.

By similar methods, a circular plate may be made to exhibit nodal lines dividing the surface by diametral lines into four or a greater, but always *even*, number of sectors, an odd number being incompatible with the general law of stationary waves that the parts of a body adjoining a nodal line on either side must always vibrate oppositely to each other.

Another class of figures consists of circular nodal lines along with diametral lines (fig. 39).

Circular nodal lines unaccompanied by intersecting lines cannot be produced in the manner described; but may be got either by drilling a small hole through the centre, and drawing a horse-hair along its edge to bring out the note, or by attaching a long thin elastic rod to the centre of the plate, at right angles to it, holding the rod by the middle and rubbing it lengthwise with a bit of cloth powdered with resin, till the rod gives a distinct note; the vibrations are communicated to the plate, which consequently vibrates transversely, and causes the sand to heap itself into one or more concentric rings.

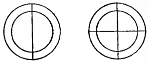

FIG. 39.

Paper, parchment, or any other thin membrane stretched over a square, circular, &c., frame, when in the vicinity of a sufficiently powerful vibrating body, will, through the medium of the air, be itself made to vibrate in unison, and, by using sand, as in previous instances, the nodal lines will be depicted to the eye, and seen to vary in form, number and position with the tension of the plate and the pitch of the originating sound. The membrana tympani or drum of the ear, has, in like manner and on the same principles, the property of repeating the vibrations of the external air which it communicates to the internal parts of the ear.

Bells may be regarded as somewhat like circular plates vibrating with radial nodes, and with the edges turned down. Lord Rayleigh has shown that there is a tangential motion as well as a motion in and out. Ordinarily when a bell is struck the impulse primarily excites the radial motion, and the tangential motion follows as a matter of course. When a finger-glass (an inverted bell), is excited by passing the finger round the circumference, the tangential motion is primarily excited and the radial follows it. Some discussion of the vibrations of bells will be found in Rayleigh, *Sound*, vol. i. ch. 10 (see also BELLS).

Singing Flames.—A " jet tube," *i.e.* a tube a few inches long with a fine nozzle at the top, is mounted as in fig. 40, so as to rise out of a vessel to which coal-gas, or, better, hydrogen, is supplied. The supply is regulated so that when the gas is lighted the flame is half or three-quarters of an inch high. A " sounding tube," say an inch in diameter, and somewhat more than twice the length of the jet tube, is then lowered over the flame, as in the figure. When the flame is at a certain distance within the tube the air is set in vibration, and the sounding tube gives out its fundamental note continuously. The flame appears to lengthen, but if the reflection is viewed in a vertical mirror revolving about a vertical axis or in Koenig's cube of mirrors, it is seen that the flame is really intermittent, jumping up and down once with each vibration, sometimes apparently going within the jet tube at its lowest point. For a given jet tube there is a position of maximum efficiency easily obtained by trial. The jet tube, for a reason which will be given when we consider the maintenance of vibrations, must be less than half the length of the sounding tube.

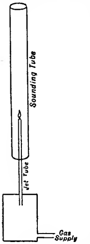

FIG. 40.—Singing Flame.

A series of pipes of lengths to give any desired series of notes may be arranged. If two tubes in unison are employed, a pretty example of resonance may be obtained. One is adjusted so as just not to sing. The other is then made to sing and frequently the first will be set singing also.

Sensitive Flames and Jets.—When a flame is just not flaring, any one of a certain range of notes sounded near it may make it flare while the note is sounding. This was first noticed by John Le Conte (*Phil. Mag.*, 1858, 15, p. 235), and later by W. F. Barrett (*Phil. Mag.*, 1867, 33, p. 216). Barrett found that the best form of burner for ordinary gas pressure might be made of glass tubing about $\frac{3}{8}$ in. in diameter contracted to an orifice $\frac{1}{16}$ inch in diameter, the orifice being nicked by a pair of scissors into a V-shape. The flame rises up from the burner in a long thin column, but when an appropriate note is sounded it suddenly drops down and thickens. Barrett further showed by using smoke jets that the flame is not essential. John Tyndall (*Sound*, lecture vi. § 7 seq.) describes a number of beautiful experiments with jets at higher pressure than ordinary, say 10 in. of water, issuing from a pinhole steatite burner. The flame may be 16 in. high, and on receiving a suitably high sound it suddenly drops down and roars. The sensitive point is at the orifice. Lord Rayleigh (*Sound*, ii. § 370), using as a source a " bird-call," a whistle of high frequency, formed a series of stationary waves by reflection at a flat surface. Placing the sensitive flame at different parts of this train, he found that it was excited, not at the nodes where the pressure varied, but at the loops where the motion was the greatest and where there was little pressure change. In his *Sound* (ii. ch. 21) he has given a theory of the sensitiveness. When the velocity of the jet is gradually increased there is a certain range of velocity for which the jet is unstable, so that any deviation from the straight rush-out tends to increase as the jet moves up. If then the jet is just on the point of instability, and is subjected as its base to alternations of motion, the sinuosities impressed on the jet become larger and larger as it flows out, and the flame is as it were folded on itself. Another form of sensitive jet is very easily made by putting a piece of fine wire gauze 2 or 3 in. above a pinhole burner and igniting the gas above the gauze. On adjusting the gas so that it burns in a thin column, just not roaring, it is extraordinarily sensitive to some particular range of notes, going down and roaring when a note is sounded. If a tube be placed over such a flame it makes an excellent singing tube. The flame of an incandescent gas mantle if turned low is frequently sensitive to a certain range of notes. Such a flame may jump down, for instance, to each tick of a neighbouring clock.

Savart's Liquid Jets.—If a jet of water issues at an angle to the horizontal from a round pinhole orifice under a few inches pressure, it travels out as an apparently smooth cylinder for a short distance, and then breaks up into drops which travel at different rates, collide, and scatter. But if a tuning-fork of appropriate frequency be set vibrating with its stalk in contact with the holder of the pipe from which the jet issues, the jet appears to go over in one continuous thread. Intermittent illumination, however, with frequency equal to that of the fork shows at once that the jet is really broken up into drops, one for each vibration, and that these move over in a steady procession. The cylindrical form of jet is unstable if its length is more than π times its diameter, and usually the irregular disturbances it receives at the orifice go on growing, and ultimately break it up irregularly into drops which go out at different rates. But, if quite regular disturbances are impressed on the jet at intervals of time which depend on the diameter and speed of outflow (they must be somewhat more than π times its diameter apart), these disturbances go on growing and break the stream up into equal drops, which all move with the same velocity one after the other. An excellent account of these and other jets is given in C. V. Boys' *Soap Bubbles*, lecture iii.

Maintenance of Vibrations.—When a system is set vibrating and left to itself, the vibration gradually dies away as the energy leaks out either in the waves formed or through friction. In order that the vibration may be maintained, a periodic force must be applied either to aid the internal restoring force on the return journey, or weaken it on the outgoing journey, or both. Thus if a pendulum always receives a slight impulse in the direction of motion just about the lowest point, this is equivalent to an increase of the restoring force if received before passage through the lowest point, and to a decrease if received after that passage, and in either case it tends to maintain the swing. If the bob of the pendulum is iron, and if a coil is placed just below the centre of swing, then, if a current passes through the coil, while and only while the bob is moving towards it, the vibration is maintained. If the current is on while the bob is receding the vibration is checked. If it is always on it only acts as if the value of gravity were increased, and does not help to maintain or check the vibration, but merely to shorten the period.

Electrically Maintained Fork.

In a common form of electrically maintained fork, the fork is set horizontal with its prongs in a vertical plane, and a small electro-magnet is fixed between them. The circuit of the electro-magnet is made and broken by the vibration of the fork in different ways—say, by a wire bridge attached to the lower prong which dips into and lifts out of two mercury cups. The mercury level is so adjusted that the circuit is just not made when the fork is at rest. When it is set vibrating contact lasts during some part of the outward and some part of the inward swing. But partly owing to the delay in making contact through the carriage down of air on the contact piece, and partly owing to the delay in establishing full current through self-induction, the attracting force does not rise at once to its full value in the outgoing journey, whereas in the return journey the mercury tends to follow up the contact piece, and the full current continues up to the instant of break. Hence the attracting force does more work in the return journey than is done against it in the outgoing, and the balance is available to increase the vibration.

Organ Pipe.

In the organ pipe—as in the common whistle—a thin sheet of air is forced through a narrow slit at the bottom of the embouchure and impinges against the top edge, which is made very sharp. The disturbance made at the commencement of the blowing will no doubt set the air in the pipe vibrating in its own natural period, just as any irregular air disturbance will set a suspended body swinging in its natural period, but we are to consider how the vibration is maintained when once set going. When the motion due to the vibration is up along the pipe from the embouchure, the air moves into the pipe from the outside, and carries the sheet-like stream in with it to the inside of the sharp edge. This stream does work on the air, aiding the motion. When the motion is reversed and the air moves out of the pipe at the embouchure, the sheet is deflected on to the outer side of the sharp edge, and no work is done against it by the air in the pipe. Hence the stream of air does work during half the vibration and this is not abstracted during the other half, and so it goes on increasing the motion until the supply of energy in blowing is equal to the loss by friction and sound.

The maintenance of the vibration of the air in the singing tube has been explained by Lord Rayleigh (*Sound*, vol. ii. § 322 *h*) as due to the way in which the heat is communicated to the vibrating air. When the air in a pipe open at both ends is vibrating in its simplest mode, the air is alternately moving into and out from the centre. During the quarter swing ending with greatest nodal pressure, the kinetic energy is changed to potential energy manifested in the increase of pressure. This becomes again kinetic in the second quarter swing, then in the third quarter it is changed to potential energy again, but now manifested in the decrease of pressure. In the last quarter it is again turned to the kinetic form. Now suppose that at the end of the first quarter swing, at the instant of greatest pressure, heat is suddenly given to the air. The pressure is further increased and the potential energy is also increased. There will be more kinetic energy formed in the return journey and the vibration tends to grow. But if the heat is given at the instant of greatest rarefaction, the increase of pressure lessens the difference from the undisturbed pressure, and lessens the potential energy, so that during the return less kinetic energy is formed and the vibration tends to die away. And what is true for the extreme points is true for the half periods of which they are the middle points; that is, heat given during the compression half aids the vibration, and during the extension half damps it. Now let us apply this to the singing tube. Let the gas jet tube be of somewhat less than half the length of the singing tube, and let the lower end of the jet tube be in a wider tube or cavity so that it may be regarded as an "open end." When the air in the singing tube is singing, it forces the gas in the jet tube to vibrate in the same period and in such phase that at the nozzle the pressure in both tubes shall be the same. The lower end of the jet tube, being open, is a loop, and the node may be regarded as in an imaginary prolongation of the jet tube above the nozzle. It is evident that the pressure condition will be fulfilled only if the motions in the two tubes are in the same direction at the same time, closing into and opening out from the nodes together. When the motion is upwards gas is emitted; when the motion is downwards it is checked. The gas enters in the half period from least to greatest pressure. But there is a slight delay in ignition, partly due to expulsion of incombustible gas drawn into the jet tube in the previous half period, so that the most copious supply of gas and heat is thrown into the quarter period just preceding greatest pressure, and the vibration is maintained. If the jet tube is somewhat longer than half the sounding tube there will be a node in it, and now the condition of equality of pressure requires opposite motions in the two at the nozzle, for their nodes are situated on opposite sides of that point. The heat communication is then chiefly in the quarter vibration just preceding greatest rarefaction, and the vibration is not maintained.

Singing Tube.

Interference of Sound.

When two trains of sound waves travel through the same medium, each particle of the air, being simultaneously affected by the disturbances due to the different waves, moves in a different manner than it would if only acted on by each wave singly. The waves are said mutually to interfere. We shall exemplify this subject by considering the case of two waves travelling in the same direction through the air. We shall then obviously be led to the following results:—

If the two waves are of equal length λ, and are in the same phase (that is, each producing at any given moment the same state of motion in the air particles), their combined effect is equivalent to that of a wave of the same length λ, but by which the excursions of the particles are increased, being the sum of those due to the two component waves respectively, as in fig. 41, 1.

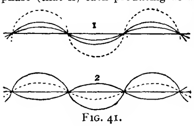

FIG. 41.

If the two interfering waves, being still of same length λ, be in opposite phases, or so that one is in advance of the other by $\frac{1}{2}\lambda$, and consequently one produces in the air the opposite state of motion to the other, then the resultant wave is one of the same length λ, but the excursions of the particles are decreased, being the difference between those due to the component waves as in fig. 41, 2. If the amplitudes of vibration which thus mutually interfere are moreover equal, the effect is the total mutual destruction of the vibratory motion.

Thus we learn that two musical notes, of the same pitch, conveyed to the ear through the air, will produce the effect of a single note of the same pitch, but of increased loudness, if they are in the same phase, but may affect the ear very slightly, if at all, when in opposite phases. If the difference of phase be varied gradually from zero to $\frac{1}{2}\lambda$, the resulting sound will gradually decrease from a maximum to a minimum.

Among the many experimental confirmations which may be adduced of these proportions we will mention the following:—

Take a circular plate, such as is available for the production of Chladni's figures, and cut out of a sheet of pasteboard a piece of the shape ABOCD (fig. 42), consisting of two circular quadrants of the same diameter as the plate. Let, now, the plate be made in the usual manner to vibrate so as to exhibit two nodal lines coinciding with two rectangular diameters. If the ear be placed right above the centre of the plate, the sound will be scarcely audible. But, if the pasteboard be interposed so as to intercept the vibrating segments AOB, DOC, the note becomes much more distinct. The reason of this is, that the segments of the plate AOD, BOC always vibrate in the same direction, but oppositely to the segments AOB, DOC. Hence, when the pasteboard is in its place, there are two waves of same phase starting from the two former segments, and reaching the ear after equal distances of transmission through the air, are again in the same phase, and produce on the ear a conjunct impression. But when the pasteboard is removed, then there is at the ear opposition of phase between the first and the second pair of waves, and consequently a minimum of sound.

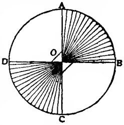

FIG. 42.

A tubular piece of wood shaped as in fig. 43, and having a piece of thin membrane stretched over the opening at the top C, some dry sand being strewn over the membrane, is so placed over a circular or rectangular vibrating plate that the ends A, B lie over the segments of the plate, such as AOD, COB in the previous figure, which are in the same state of motion. The sand at C will be set in violent movement. But if the same ends A, B be placed over oppositely vibrating segments (such as AOD, COD), the sand will be scarcely, if at all, affected.

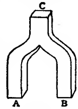

FIG. 43.

If a tuning-fork in vibration be turned round before the ear, four positions will be found in which it will be inaudible, owing to the mutual interference of the oppositely vibrating prongs of the fork. On interposing the hand between the ear and either prong of the fork when in one of those positions, the sound becomes audible, because then one of the two interfering waves is cut off from the ear. This experiment may be varied by holding the fork over a glass jar into which water is poured to such a depth that the air-column within reinforces the note of the fork when suitably placed, and then turning the fork round.

Helmholtz's double siren is well calculated for the investigation of the laws of interference of sound. For this purpose a simple mechanism is found in the instrument, by means of which the fixed upper plate can be turned round and placed in any position relatively to the lower one. If, now, the apparatus be so set that the notes from the upper and lower chest are in unison, the upper fixed plate may be placed in four positions, such as to cause the air-current to be cut off in the one chest at the exact instant when it is freely passing through the other, and vice versa. The two waves, therefore, being in opposite phases, neutralize one another, and the result is a faint sound. On turning round the upper chest into any intermediate position, the intensity of the sound will increase up to a maximum, which occurs when the air in both chests is being admitted and cut off contemporaneously.

If two organ pipes in unison are mounted side by side on a wind-chest with their ends close together, and are blown for a very short time, they sound. But if the blowing is continued, usually in less than a second the sound dies away to a small fraction of that due to either alone. Yet the air within the pipes is vibrating more vigorously than ever, but in opposite phases in the two pipes. This may be shown by furnishing the pipes with manometric flames placed in the same vertical line. When the flames are viewed in a revolving mirror and the pipes are blown, each image of one flame lies between two images of the other. The essential fact, as pointed out by Lord Rayleigh (*Scientific Papers*, i. 409), is not the common wind chest, but the nearness of the open ends, so that the outrush from one pipe can supply the inrush to the other, and the converse. If, the two pipes are slightly out of tune when sounded separately together they sound a common note which may be higher than that due to either alone. Lord Rayleigh (*loc. cit.*) points out that this is due to reduction of the end correction. When the air rushes out from one pipe, it has not to force its way into the open air, but finds a cavity being prepared for it close at hand in the other pipe, and so the extensions and compressions at the ends are more easily reduced. Even the longer pipe may be effectively shorter than the corrected shorter pipe when sounding alone.

Beats.

When two notes are not quite in unison the resulting sound is found to alternate between a maximum and minimum of loudness recurring periodically. To these periodical alternations has been given the name of *Beats*. Their origin is easily explicable. Suppose the two notes to correspond to 200 and 203 vibrations per second; at some instant of time, the air particles, through which the waves are passing, will be similarly displaced by both, and consequently the joint effect will be a sound of some intensity. But, after this, the first or less rapidly vibrating note will fall behind the other, and cause a diminution in the joint displacements of the particles, till, after the lapse of one-sixth of a second, it will have fallen behind the other by half a vibration. At this moment, therefore, opposite displacements will be produced of the air particles by the two notes, and the sound due to them will be at a minimum. This will be followed by an increase of intensity until the lapse of another sixth of a second, when the less rapidly vibrating note will have lost another half-vibration relatively to the other, or one vibration reckoning from the original period of time, and the two component vibrations will again conspire and reproduce a maximum effect. Thus, an interval of one-third of a second elapses between two successive maxima or beats, and there are produced three beats per second. By similar reasoning it may be shown that the number of beats per second is always equal to the difference between the numbers of vibrations in the same time corresponding to the two interfering notes. The more, therefore, these are out of tune the more rapidly will the beats follow each other.

The formation of beats may be illustrated by considering the disturbance at any point due to two trains of waves of equal amplitude a and of nearly equal frequencies n_1 n_2. If we measure the time from an instant at which the two are in the same phase the resultant disturbance is

$$\begin{aligned} y &= a \sin 2\pi n_1 t + a \sin 2\pi n_2 t \\ &= 2a \cos \pi(n_1 - n_2)t \sin \pi(n_1 + n_2)t, \end{aligned}$$

which may be regarded as a harmonic disturbance of frequency $(n_1+n_2)/2$ but with amplitude $2a \cos \pi(n_1-n_2)t$ slowly varying with the time. Taking the squares of the amplitude to represent the intensity or loudness of the sound which would be heard by an ear at the point, this is

$$\begin{aligned} &4a^2 \cos^2 \pi(n_1 - n_2)t \\ &= 2a^2\{1 + \cos 2\pi(n_1 - n_2)t\}, \end{aligned}$$

a value which ranges between 0 and $4a^2$ with frequency n_1-n_2. The sound swells out and dies down n_1-n_2 times per second, or there are n_1-n_2 beats per second. If, instead of considering one point in a succession of instants, we consider a succession of points along the line of propagation at the same instant, we evidently have waves of amplitude varying from $2a$ down to 0, and then up to $2a$ again in distance $U/(n_1-n_2)$.

The phenomena of beats may be easily observed with two organ-pipes put slightly out of tune by placing the hand near the open end of one of them, with two musical strings on a resonant chest, or with two tuning-forks of the same pitch mounted on their resonance boxes, or held over a resonant cavity (such as a glass jar), one of the forks being put out of tune by loading one prong with a small lump of beeswax. In the last instance, if the forks are fixed on one solid piece of wood which can be grasped with the hand, the beat will be actually felt by the hand. If one prong of each fork be furnished with a small plain mirror, and a beam of light from a luminous point be reflected successively by the two mirrors, so as to form an image on a distinct screen, when one fork alone is put in vibration, the image will move on the screen and be seen as a line of a certain length. If both forks are in vibration, and are prefectly in tune, this line may either be increased or diminished permanently in length according to the difference of phase between the two sets of vibrations. But if the forks be not quite in tune then the length of the image will be found to fluctuate between a maximum and a minimum, thus making the beats sensible to the eye. The vibrograph is also well suited for the same purpose, and so in an especial manner is Helmholtz's double siren, in which, by continually turning round the upper box, a note is produced by it more or less out of tune with the note formed by the lower chest, according as the handle is moved more or less rapidly, and most audible beats ensue. We have already explained how beats are used on Scheibler's tonometer to give a series of forks of known frequencies. Beats also afford an excellent practical guide in the tuning of instruments, but more so for the higher notes of the register, inasmuch as the same number of beats are given by a smaller deviation from unison by two notes of high pitch than by two notes of low pitch. Thus, two low notes of 32 and 30 vibrations respectively, whose interval is therefore $\frac{32}{30}$ or $\frac{16}{15}$, *i.e.* a semitone, give two beats per second, while the same number of beats are given by notes of 32×16 (four octaves higher than the first of the preceding) or 512, and 514 vibrations, which are only slightly out of tune.

Beats and Dissonance.—As the interval between two tones, and consequently the number of beats, increases the effect on the ear becomes more and more unpleasant. The sound is jarring and harsh, and we term it a "dissonance" or "discord." In the middle notes of the musical register the maximum harshness occurs when the beats are about 30. Thus the interval $b'c''$ with frequencies 495 and 528, giving 33 beats in a second, is very dissonant. But the interval $b'\flat c''$ gives nearly twice as many beats and is not nearly so dissonant. The minor third $a'c''$ with 88 beats per second shows scarcely any roughness, and when the beats rise to 132 per second the result is no longer unpleasant.

We are then led to conclude that beats are the physical foundation for dissonance. The frequency of beats giving maximum dissonance rises as we rise higher in the musical scale, and falls as we descend. Thus $b''c'''$ and $b'\flat c''$ have each 66 beats per second, yet the former is more dissonant than the latter. Again $b'c''$ and CG have each 33 beats per second, yet the latter interval is practically smooth and consonant. This beat theory of dissonance was first put forward by Joseph Sauveur (1653–1716) in 1700. Robert Smith (*Harmonics*, 2nd ed., 1759, p. 95) states that Sauveur "inferred that octaves and other simple concords, whose vibrations coincide very often, are agreeable and pleasant because their beats are too quick to be distinguished, be the pitch of the sounds ever so low; and on the contrary, that the more complex consonances whose vibrations coincide seldom are disagreeable because we can distinguish their slow beats; which displease the ear, says he, by reason of the inequality of the sound. And in pursuing this thought he found that those consonances which beat faster than six times in a second are the very same that musicians treat as concords; and that others which beat slower are the discords; and he adds that when a consonance is a discord at a low pitch and a concord at a high one, it beats sensibly at the former pitch but not at the latter." But Sauveur fixed the limiting number of beats for the discord far too low, and again he gave no account of dissonances such as the seventh, where the frequency of the beats between the fundamentals is far beyond the number which is unpleasant. Smith, though recognizing the unpleasantness of beats, could not accept Sauveur's theory, and, indeed, it received no acceptance till it was rediscovered by Helmholtz, to whose investigations, recorded in his *Sensations of Tone*, we owe its satisfactory establishment.

Suppose that we start with two simple tones in unison; there is perfect consonance. If one is gradually raised in pitch beating begins, at first easily countable. But as the pitch of the one rises the beats become a jar too frequent to count, and only perhaps to a trained ear recognizable as beats. The two tones are now dissonant, and, as we have seen, about the middle of the scale the maximum dissonance is when there are between 30 and 40 beats per second. If the pitch is raised still further the dissonance lessens, and when there are about 130 beats per second the interval is consonant. If all tones were pure, dissonance at this part of the scale would not occur if the interval were more than a third. But we have to remember that with strings, pipes and instruments generally the fundamental tone is accompanied by overtones, called also "upper partials," and beating within the dissonance range may occur between these overtones.

Thus, suppose a fundamental 256 has present with it overtone harmonics 512, 768, 1024, 1280, &c., and that we sound with it the major seventh with fundamental 480, and having harmonics 960, 1440, &c. The two sets may be arranged thus

c	256		512	768		1024	1280	
b		480			960			1440,

and we see that the fundamental of the second will beat 32 times per second with the first overtone of the first, giving dissonance. The first overtone of the second will beat 64 times per second with the third of the first, and at such height in the scale this frequency will be unpleasant. The very marked dissonance of the major seventh is thus explained. We can see, too, at once how the octave is such a smooth consonance. Let the two tones with their harmonic overtones be

256	512	768	1024	1280	1536
	512		1024		1536.

The fundamental and overtones of the second all coincide with overtones of the first.

Take as a further example the fifth with harmonic overtones as under

256		512	768	1024		1280	1536
	384		768		1152		1536.

The fundamental and overtones of the second either coincide with or fall midway between overtones in the first, and there is no approach to a dissonant frequency of beats, and the concord is perfect.

But obviously in either the octave or the fifth, if the tuning is imperfect, beats occur all along the line wherever the tones should coincide with perfect tuning. Thus it is easy to detect a want of tuning in these intervals.

The harshness of deep notes on instruments rich in overtones may be explained as arising from beats between successive overtones. Thus, if a note of frequency 64 is sounded, and if all the successive overtones are present, the difference of frequency will be 64, and this is an unpleasant interval when we get to the middle of the scale, say to overtones 256 and 320 or to 512 and 576. Thus Helmholtz explains the jarring and braying which are sometimes heard in bass voices. These cases must serve to illustrate the theory. For a full discussion see his *Sensations of Tone*, ch. 10.

Dissonance between Pure Tones.—When two sources emit only pure tones we might expect that we should have no dissonance when, as in the major seventh, the beat frequency is greater than the range of harshness. But the interval is still dissonant, and this is to be explained by the fact that the two tones unite to give a third tone of the frequency of the beats, easily heard when the two primary tones are loud. This tone may be within dissonance range of one of the primaries. Thus, take the major seventh with frequencies 256 and 480. There will be a tone frequency $480-256=224$, and this will be very dissonant with 256.

The tone of the frequency of the beats was discovered by Georg Andreas Sorge in 1740, and independently a few years later by Giuseppe Tartini, after whom it is named. It may easily be heard when a double whistle with notes of different pitch is blown strongly, or when two gongs are loudly sounded close to the hearer. It is heard, too, when two notes on the harmonium are loudly sounded. Formerly it was generally supposed that the Tartini tone was due to the beats themselves, that the mere variation in the amplitude was equivalent, as far as the ear is concerned, to a superposition on the two original tones of a smooth sine displacement of the same periodicity as that variation. This view has still some supporters, and among its recent advocates are Koenig and Hermann. But it is very difficult to suppose that the same sensation would be aroused by a truly periodic displacement represented by a smooth curve, and a displacement in which the period is only in the amplitude of the to-and-fro motion, and which is represented by a jagged curve. No explanation is given by the supposition; it is merely a statement which can hardly be accepted unless all other explanations fail.

Combination Tones.—Helmholtz has given a theory which certainly accounts for the production of a tone of the frequency of the beats and for other tones all grouped under the name of "combination tones"; and in his *Sensations of Tone* (ch. 11) he examines the beats due to these combination tones and their effects in producing dissonance. The example we have given above of the major seventh must serve here. The reader is referred to the full discussion by Helmholtz. We shall conclude by a brief account of the ways in which combination tones may be produced. There appears to be no doubt that they are produced, and the only question is whether the theory accounts sufficiently for the intensity of the tones actually heard.

Combination tones may be produced in three ways: (1) In the neighbourhood of the source; (2) in the receiving mechanism of the ear; (3) in the medium conveying the waves.

1. We may illustrate the first method by taking a case discussed by Helmholtz (*Sensations of Tone*, app. xvi.) where the two sources are reeds or pipes blown from the same wind-chest. Let us suppose that with constant excess of pressure, p, in the wind-chest, the amplitude produced is proportional to the pressure, so that the two tones issuing may be represented by $pa \sin 2\pi n_1 t$ and $pb \sin 2\pi n_2 t$. Now as each source lets out the wind periodically it affects the pressure in the chest so that we cannot regard this as constant, but may take it as better represented by $p+\lambda a \sin(2\pi n_1 t+e)+\mu b \sin(2\pi n_2 t+f)$. Then the issuing disturbance will be

$$\begin{aligned}\{p+\lambda a \sin(2\pi n_1 t+e)+\mu b \sin(2\pi n_2 t+f)\}\{a \sin 2\pi n_1 t+b \sin 2\pi n_2 t\}\\ =pa \sin 2\pi n_1 t+pb \sin 2\pi n_2 t\\ +\frac{a^2\lambda}{2}\cos e-\frac{a^2\lambda}{2}\cos(4\pi n_1 t+e)\\ +\frac{b^2\mu}{2}\cos f-\frac{b^2\mu}{2}\cos(4\pi n_2 t+f)\\ +\frac{ab\lambda}{2}\cos\{2\pi(n_1-n_2)t+e\}-\frac{ab\lambda}{2}\cos\{2\pi(n_1+n_2)t+e\}\\ +\frac{ab\mu}{2}\cos\{2\pi(n_1-n_2)t-f\}-\frac{ab\mu}{2}\cos\{2\pi(n_1+n_2)t+f\} \qquad (35)\end{aligned}$$

Thus, accompanying the two original pure tones there are (1) the octave of each; (2) a tone of frequency (n_1-n_2); (3) a tone of frequency (n_1+n_2). The second is termed by Helmholtz the ***difference tone***, and the third the *summation tone*. The amplitudes of these tones are proportional to the products of a and b multiplied by λ or μ. These combination tones will in turn react on the pressure and produce new combination tones with the original tones, or with each other, and such tones may be termed of the second, third, &c., order. It is evident that we may have tones of frequency

$$hn_1 \qquad kn_2 \qquad hn_1-kn_2 \qquad hn_1+kn_2,$$

where h and k are any integers. But inasmuch as the successive orders are proportional to $\lambda\ \lambda^2\ \lambda^3$, or $\mu\ \mu^2\ \mu^3$, and λ and μ are small, they are of rapidly decreasing importance, and it is not certain that any beyond those in equation (35) correspond to our actual sensations. The combination tones thus produced in the source should have a physical existence in the air, and the amplitudes of those represented in (35) should be of the same order. The conditions assumed in this investigation are probably nearly realized in a harmonium and in a double siren of the form used by Helmholtz, and in these cases there can be no doubt that actual objective tones are produced, for they may be detected by the aid of resonators of the frequency of the tone sought for. If the tones had no existence outside the ear then resonators would not increase their loudness. There is not much difficulty in detecting the difference tone by a resonator if it is held, say, close to the reeds of a harmonium, and Helmholtz succeeded in detecting the summation tone by the aid of a resonator. Further, Rücker and Edser, using a siren as source, have succeeded in making a fork of the appropriate pitch respond to both difference and summation tones (*Phil. Mag.*, 1895, 39, p. 341. But there is no doubt that it is very difficult to detect the summation tone by the ear, and many workers have doubted the possibility, notwithstanding the evidence of such an observer as Helmholtz. Probably the fact noted by Mayer (*Phil. Mag.*, 1878, 2, p. 500, or Rayleigh, *Sound*, § 386) that sounds of considerable intensity when heard by themselves are liable to be completely obliterated by graver sounds of sufficient force goes far to explain this, for the summation tones are of course always accompanied by such graver sounds.

2. The second mode of production of combination tones, by the mechanism of the receiver, is discussed by Helmholtz (*Sensations of Tone*, App. xii.) and Rayleigh (*Sound*, i. § 68). It depends on the restoring force due to the displacement of the receiver not being accurately proportional to the displacement. This want of proportionality will have a periodicity, that of the impinging waves, and so will produce vibrations just as does the variation of pressure in the case last investigated. We may see how this occurs by supposing that the restoring force of the receiving mechanism is represented by $\lambda x+\mu x^2$, where x is the displacement and μx^2 is very small. Let an external force F act on the system, and for simplicity suppose its period is so great compared with that of the mechanism that we may take it as practically in equilibrium with the restoring force. Then $F=\lambda x+\mu x^2$. Now μx^2 is very small compared with λx, so that x is nearly equal to F/λ, and as an approximation, $F=\lambda x+\mu F^2/\lambda^2$, or $x=F/\lambda-\mu F^2/\lambda^3$. Suppose now that $F=a \sin 2\pi n_1 t+b \sin 2\pi n_2 t$, the second term will evidently produce a series of combination tones of periodicities $2n_1$, $2n_2$, n_1-n_2, and n_1+n_2, as in the first method. There can be no doubt that the ear is an unsymmetrical vibrator, and that it makes combination tones, in some such way as is here indicated, out of two pure tones. Probably in most cases the combination tones which we hear are thus made, and possibly, too, the tones detected by Koenig, and by him named "beat-tones." He found that if two tones of frequencies p and q are sounded, and if q lies between Np and $(N+1)p$, then a tone of frequency either $(N+1)p-q$, or of frequency $q-Np$, is heard. The difficulty in Helmholtz's theory is to account for the audibility of such beat tones when they are of a higher order than the first. Rücker and Edser quite failed to detect their external existence, so that apparently they are not produced in the source. If we are to assume that the tones received by the ear are pure and free from partials, the loudness of the beat-tones would appear to show that Helmholtz's theory is not a complete account.

3. The third mode of production of combination tones, the production in the medium itself, follows from the varying velocity of different parts of the wave, as investigated at the beginning of this article. It is easily shown that after a time we shall have to superpose on the original displacement a displacement proportional to the square of the particle velocity, and this will introduce just the same set of combination tones. But probably in practice there is not a sufficient interval between source and hearer for these tones to grow into any importance, and they can at most be only a small addition to those formed in the source or the ear.

Bibliography.—For the history of experimental and theoretical acoustics see F. Rosenberger, *Geschichte der Physik* (1882–1890); J. C. Poggendorff, *Geschichte der Physik* (1879); and E. Gerland and F. Traumüller, *Geschichte der physikalischen Experimentierkunst* (1899). The standard treatise on the mathematical theory is Lord Rayleigh's *Theory of Sound* (2nd ed., 1894); this work also contains an account of experimental verifications. The same author's *Scientific Papers* contains many experimental and mathematical contributions to the science. H. von Helmholtz treats the theoretical aspects of sound in his *Vorlesungen über die mathematischen*

Principien der Akustik (1898), and the physiological and psychical aspects in his *Die Lehre von den Tonempfindungen* (1st ed., 1863; 5th ed., 1896), English translation by A. J. Ellis, *On the Sensations of Tone* (1885). Sedley Taylor, *Sound and Music* (1882), contains a simple and excellent account of Helmholtz's theory of consonance and dissonance. R. Koenig, *Quelques expériences d'acoustique* (1882) describes apparatus and experiments, intended to show, in opposition to Helmholtz, that beats coalesce into tones, and also that the quality of a note is affected by alteration of phase of one of its component overtones relative to the phase of the fundamental. Lamb, *The Dynamical Theory of Sound* (1910), is intended as a stepping-stone to the study of the writings of Helmholtz and Rayleigh. Barton, *A Text-Book on Sound* (1908), aims to provide students with a text-book on sound, embracing both its experimental and theoretical aspects. J. H. Poynting and J. J. Thomson, *Sound* (5th ed., 1909), contains a descriptive account of the chief phenomena, and an elementary mathematical treatment. John Tyndall, *Sound* (5th ed., 1893), originally delivered as lectures, treats the subject descriptively, and is illustrated by a large number of excellent experiments. Good general accounts are given in J. L. G. Violle, *Cours de physique*, tome ii., "Acoustique"; A. Winkelmann, *Handbuch der Physik*, Band ii., "Akustik"; Müller-Pouillet, *Lehrbuch der Physik*, (1907), ii. 1; L. A. Zellner, *Vorträge über Akustik* (1892), pt. 1, physical; pt. 2, physiological; R. Klimpert, *Lehrbuch der Akustik* (1904–1907); A. Wüllner, *Lehrbuch der Experimentalphysik* (1907), 6th ed., vol. i.; and C. L. Barnes, *Practical Acoustics* (1898), treats the subject experimentally. (J. H. P.)

SOUND, THE (Danish *Oresund*), the easternmost of the straits giving entrance to the Baltic Sea from the Cattegat, between the Danish island of Zealand and Sweden. Its extreme length reckoned from the promontory of Kullen to that of Falsterbo, both on the Swedish shore, is 70 m. Its narrowest point is between Helsingör in Denmark and Helsingborg in Sweden, which are 3 m. apart. Its extreme width, 30 m., is towards the south, where Kjöge Bay indents the coast of Zealand. Three islands lie in it—Hven, belonging to Sweden, and Saltholm and Amager (which is separated from Zealand by a narrow channel at Copenhagen), belonging to Denmark. The strait between Amager and Saltholm is called Drogden, and is followed by the larger vessels passing through the Sound. The extreme depth of the Sound is about 14 fathoms. Navigation is open in winter, though three instances are recorded of the Sound being frozen completely over: in 1306, 1830 and 1836. From the 15th century Denmark levied "Sound dues" on foreign vessels passing through the strait, the Hanse traders and certain others being exempt. In the 17th century quarrels arose on this matter between Denmark and the Netherlands and Sweden, while in modern times the powers found the dues irksome, and in 1843 and 1853 protests were made by the representatives of the United States of America, but Denmark based her right on immemorial custom, and adhered to it. In 1856 the matter came up in connexion with the renewal of the treaty of 1826 between the two countries; considerable tension resulted, and the possibility of reprisals by the United States against the Danish possessions in the West Indies was discussed. But the treaty was provisionally extended to the following year, and a conference in Copenhagen, at which most of the affected powers were represented, resulted in the remission of the dues from the 1st of April 1857, Denmark receiving a united compensation of 30,476,325 rix-dollars (equalling about £4,000,000), out of which the amount paid by the British government was £1,125,000. The annual income accruing to Denmark from the dues during the ten previous years had been about 2,500,000 rix-dollars.

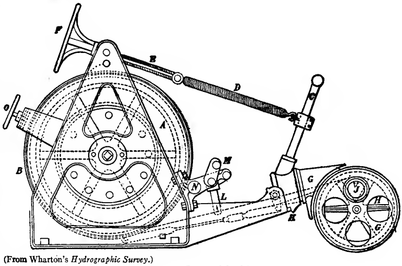
SOUNDING (for derivation see SOUND above), the term used for measuring the depth of water (and so, figuratively, of anything). The process of ascertaining the depth of the sea has been practised from very early times for purposes of navigation, but it is only since the introduction of submarine telegraphy that extensive efforts have been made to obtain a complete knowledge of the contour of the ocean-bed (see OCEAN).

The operation of sounding is readily performed in shallow water by letting down a weight or "lead" attached to a cord, which is marked off into fathoms by pieces of leather, rag and twine. The bottom of the weight usually presents a hollow, which is filled with tallow, so that a portion of the material from the bottom may be brought up and give an indication of its nature as well as an assurance that it has really been touched.

For depths over 20 fathoms sounding machines are often employed, and for deep soundings they are practically indispensable. In them wire, the use of which for this purpose was introduced by Sir William Thomson (Lord Kelvin), has entirely superseded hemp gear. Its smooth surface and minute section, reducing friction to a minimum, give a rapidity of descent of about 100 fathoms per minute, and this velocity is not materially diminished even at great depths. Reeling in may be accomplished at nearly the same rate. Soundings are thus obtained with a degree of accuracy not formerly possible. The apparatus is light, compact and automatic in its action. Soundings with wire can be carried out at night with the same facility as in daytime, and in almost any circumstances of wind and weather short of a strong gale, against which the ship could not steam or face the sea. A sounding of 1000 fathoms may be obtained in twenty-five minutes from the time the weight is lowered to the time the order is given to put the ship on her course, or in half that time if sounding from astern and going ahead on getting bottom; 2000 fathoms will require forty-five minutes and 3000 fathoms seventy-five minutes. Beyond that depth, much greater caution being required, the time occupied is correspondingly increased, and reeling in must then be done very deliberately. A sounding of 5269 fathoms was obtained near the island of Guam by the U.S. cable-surveying ship "Nero." Soundings at such depths may occupy as long as five or six hours.

Lucas Machine.

Among the sounding machines in general use the Lucas carries nearly 6000 fathoms of 20-gauge wire, and is fitted with two brakes—one a screw brake for holding the reel when required, the other an automatic brake for stopping the reel when the weights strike the bottom. A guider for the purpose of winding the wire uniformly on to the reel is also attached, and is worked by a small handle. After leaving the reel the wire passes over a registering wheel, the dial of which indicates the amount of wire run out. Similar machines of smaller size are supplied for use in boats. The large machine is represented in fig. 1.



(From Wharton's *Hydrographic Survey*.)

FIG. 1.—Lucas Machine.

H, Measuring wheel.
J, Indicator.
K, Stop.
L, Wire guiding roller.
M, Handle for working roller.
N, Bolt.
O, Screw Brake.

Heaving in is accomplished by means of a hemp "swifter" or driving belt, which conveys the motion of the drum of a donkey engine to the drum carrying the wire of the sounding machine. It being impracticable to regulate the speed of the engine by hand according to the heave of the ship, in order to obviate the sudden and excessive strains on the wire so caused, an ingenious mechanical arrangement has been fitted by which frictional disks, geared by cog-wheels and capable of adjustment are interposed on the axle connecting the grooved wheel actuated by the hemp swifter and the revolving drum carrying the wire. By this arrangement the latter can be controlled as desired, both in speed and direction of motion, by means of a lever regulating the strap on the frictional disks, which may be set by experiment to act at any given tension of the wire. As the tension approaches this limit, the velocity of revolution of the drum is automatically checked; and if the tension further increases, the motion of the drum is actually reversed, thus causing the wire to run out, until the tension is relieved sufficiently to allow the frictional disks again to act in the direction of heaving in. The drum may be stopped instantly by moving the lever in the proper direction to throw the apparatus out of gear.

Galvanized-steel wire of 20-gauge and 21-gauge is supplied on drums in lengths of 5000 fathoms. The 20-gauge wire when new has a breaking strain of 240 lb, and the smaller wire 190 lb. The large machines will hold sufficient quantity of the larger wire for the deepest soundings; there is therefore no longer any necessity for the smaller wire, and its use is not recommended. The zinc wears off to a considerable extent with constant use; it is necessary to pass the wire through an oily wad whenever soundings are suspended for a time, and the surface layers on the drum should be kept well coated with oil and covered over with oily waste. A fortnight's continuous use is about the limit to the trustworthiness of any piece of wire; no amount of care will prevent it from becoming brittle; and directly it can be snapped by twisting in the hand, it should be condemned and passed on to the boats' machines. A magnifying glass will assist in examining its condition. Taut and even winding on the reel from the drum is most important; otherwise, when heaving up after a sounding, the strain forces each layer as it comes in to sink down amongst the previous layers loosely reeled on, with the result that at the next sounding slack turns will suddenly develop on running out, to the great risk of the wire. The wire is liable to cut grooves in the interior of the swivelling frame; a file must constantly be applied to smooth these down, or they will rip the splices. A roller of hard steel, underneath which wire passes, and which placed in rear of the swivelling frame, obviates this to a great extent.

Splices are made about 5 ft. in length, one wire being laid round the other in a long spiral of about one turn per inch. A seizing of fine wire is laid over each end and for 2 or 3 in. up the splice, no end being allowed to project, and solder is then applied the whole length of the splice. Three more seizings should be placed at intervals. Splices are the weakest parts of the wire, and their multiplication is to be avoided. They should be frequently examined and their position noted, so that in heaving in they may be eased round the wheel with the guider nearly in the centre, to avoid tearing.

Sounding Rods and Sinkers. Under 1000 fathoms a lead of 30 to 40 lb weight can be recovered, and no detaching rod is necessary. At a little risk to the wire, when sounding from astern up to that depth, the ship may go ahead directly bottom is struck, increasing speed as the wire comes in; the great saving in time thus effected will often justify the increased risk of parting the wire. For greater depths the "Driver rod" is the best detaching apparatus for slipping the sinkers; its construction is easier than that of the "Baillie rod," and with a piece of gas piping cut to the proper length the ship's blacksmith can make one in a day. Both rods are fitted with tubes to bring up a specimen of the bottom, and the same sinkers fit them both.

The "Driver rod" is shown in fig. 2. ABC is a tube about 2 ft. in length, fitted at the top with a flap valve D, working on a hinge at E. The lower part of the tube C screws on and off, and contains a double flap valve to retain the bottom specimen. The sinkers WW, each 25 lb in weight, conical in form, and pierced with a cylindrical hole through which the Driver rod passes loosely, are slung by wire or cod line secured to a flat ring or grummet shown at L and passing over the stud G. A stud K on each side of the tube fits loosely into the slot H in the lower part of the slipping lever MH. The weight of the apparatus being taken by the sounding wire, the sinkers remain suspended; but on striking the bottom, the wire slackens, and the weight of the sinkers drags the slipping lever down till the stud K bears against the upper part of the slot H. By this action the point M of the slipping lever is brought to bear against the upper end of the standard EF, being thereby forced outward sufficiently to ensure that the weight acting at the point G will tilt the slipping lever right over, and thus disengage the sling. The tube being then drawn up the sinkers are left behind. In descending, the valves at top and bottom, opening upwards, allow the water to pass through freely; but on drawing up they are closed, thus retaining the plug of mud with which the tube is filled. For water under 2000 fathoms two conical weights are sufficient. In deeper water a third cylindrical weight of 20 lb should be put between them. It is important to interpose a piece of hemp line, some 10 fathoms long, between the end of the wire (into which a thimble is seized) and the lead or rod. This tends to prevent the wire from kinking on the lead striking the bottom. A piece of sheet lead, about 2 lb in weight, wrapped round the hemp just below the junction, keeps the wire taut while the hemp slacks. Small brass screw stoppers, fitted with a hempen tail to secure to a cleat, hold the wire during the sounding if necessary to repair splices or clear slack turns. In heaving in the springs are replaced with a spring balance, by which the amount of strain is seen and the deck engine worked accordingly. A system of signals is required by day and by night, by which the officer superintending the sounding can control the helm, main engines and deck engine.

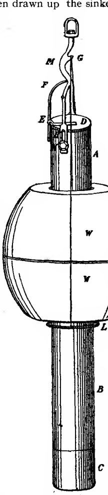

FIG. 2.—Driver Rod.

Method of Sounding.—The machine is placed on a projecting platform on the forecastle. An endless hemp swifter, led through blocks with large sheaves, connects the sounding machine and deck engine, and when heaving in is kept taut by a snatch block set up with a jigger. As the wire runs out, the regulating screw of the brake must be gradually screwed up, so as to increase the power of the brake in proportion to the amount of wire out. The regulating screw is marked for each 500 fathoms. In fairly smooth water the brake will at once act when the weight strikes the bottom and the reel stops. Under 3000 fathoms one spring only is sufficient, but beyond that depth two springs are required. If the ship is pitching heavily, the automatic brake must be assisted by the screw brake to ensure the reel not overrunning. The marks on the regulating screw are only intended as a guide; the real test is that the brake is just on the balance, so as to act when the strain lessens, which may be known by the swivelling frame being just lifted off the stop. As the wire weighs $7\frac{1}{2}$ lb for each 500 fathoms, the 500-fathoms mark on the screw should be at the position in which the screw has to be to sustain a weight of $7\frac{1}{2}$ lb; the 1000-fathoms mark, 15 lb; and so on. This can be tested and the marks verified.

Handling the Ship.—Sounding from forward enables the ship to be handled with greater ease to keep the wire up and down, and especially so in a tide-way; but in very heavy weather soundings may be obtained from a machine mounted over the stern, when it would be quite impossible to work on the forecastle. The spanker must be set with the sheet to windward, unless a strong weather tide renders it undesirable; the ship's head must be kept in a direction which is the resultant of the direction and force of the wind and current; and this is arrived at by altering the course while sounding, point by point, until the wire can be kept up and down by moving the engines slowly ahead as necessary. It should seldom, or never, be necessary to move the engines astern.

Observations of Temperature. The temperature of the water is usually taken at intervals of 100 fathoms down to a depth of 1000 fathoms, and at closer intervals in the first 100 fathoms. If a second wire machine is available, the observations may be made from aft whilst the sounding is being taken forward. A 30-lb sinker is attached to the end of the wire, and the registering thermometers are secured to the wire by the metal clips at the back of the cases, at the required intervals. To avoid heavy loss, not more than four thermometers should be on the wire at one time. When sounding a thermometer is usually attached to the line a short distance above the lead.

The primary object of the machine called the "submarine sentry" is to supply an automatic warning of the approach of a ship to shallow water: it has been instrumental in discovering many unsuspected banks in imperfectly surveyed waters. By means of a single stout wire the sinker, an inverted kite, called the "sentry," can be towed steadily for any length of time, at any required vertical depth down to 40 fathoms with the red kite and 30 fathoms with the black kite; should it strike the bottom, through the water shallowing to less than the set depth, it will at once free itself and rise to the surface, simultaneously sounding an alarm on board, and thus giving instant

Submarine Sentry.

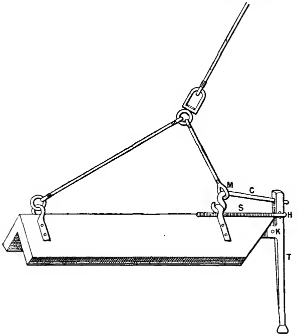

FIG. 3.—The Submarine Sentry.

warning. The vertical depth at which the sentry sets itself when a given length of wire is paid out is not changed by any variation of speed between 5 and 13 knots, and is read off on the graduated dial-plate on the winch. One set of graduations on the dial indicates the amount of wire out; the other two sets refer to the red and black kites respectively, and show the depth at which the sentry is towing. By this machine single soundings down to 40 fathoms can be taken at any time while the ship is under way. The sentry being let down slowly, the gong will indicate when the bottom is touched, and the dial corresponding to the kite used will show at once the vertical depth at the place where the sentry struck.

By removing the kite and substituting a lead, with atmospheric sounder or other automatic depth gauge, flying single soundings up to 100 fathoms can be obtained in the ordinary manner without stopping the ship. The winch is secured to the deck a short distance from the stern; the towing wire passes from the drum under a roller fairlead at the foot of the winch, thence through an iron block with sheave of large diameter, suspended from a short davit on the stern rail and secured to the sling of the sentry. The dial being set to zero with the sentry at the water's edge, the ship's speed is reduced to 8 or 9 knots, and the wire paid out freely until the kite is fairly in the water, when the brake should be applied steadily and without jerking, veering slowly until the required depth is attained, when the pawl is put on the rachet wheel and the speed increased to 12 knots if desired when using the black kite or 10 knots with the red kite.

The kite in its position when being towed is indicated in fig. 3. The point of the catch C, passing through a thimble M in the short leg of the sling, is slipped into the hole at the top of trigger T, which is hinged at K and kept in its place by the spring S attached to the hook H. On the trigger striking the bottom the catch is released, the short leg of the sling slips off, and the sentry, which then rises to the surface, is left towing by the long leg. The winch is fitted with two handles for heaving in the wire; one gives great power and slow speed, and the other, acting on the drum spindle direct, winds in quickly. The wire supplied with the machine has a steady breaking strain of about 1000 lb. Using the black kite at a speed of 7 knots, the strain on the wire is about 150 lb, and at 10 knots about 300 lb. The red kite increases the strain largely. (A. M. F.*)

SOUSA, LUIZ DE [MANOEL DE SOUSA COUTINHO] (1555–1632), Portuguese monk and prose-writer, was born at Santarem, a member of the noble family of Sousa Coutinho. In 1576 he broke off his studies at Coimbra University to join the order of Malta, and shortly afterwards was captured at sea by Moorish pirates and taken prisoner to Argel, where he met Cervantes. A year later Manoel de Sousa Coutinho was ransomed, and landing on the coast of Aragon passed through Valencia, where he made the acquaintance of the poet Jaime Falcão, who seems to have inspired him with a taste for study and a quiet life. The national disasters and family troubles increased this desire, which was confirmed when he returned to Portugal after the battle of Alcacer and had the sorrow of witnessing the Spanish invasion and the loss of his country's independence. Between 1584 and 1586 he married a noble lady, D. Magdalena de Vilhena, widow of D. John of Portugal, the son of the poet D. Manoel of Portugal, to whom Camoens had dedicated his seventh ode. Settling at Almada, on the Tagus opposite Lisbon, he divided his time between domestic affairs, literary studies and his military duties as colonel of a regiment. His patriotic dislike of an alien rule grew stronger as he saw Portugal exploited by her powerful partner, and it was ultimately brought to a head in 1599. In that year, to escape the pest that devastated Lisbon, the governors of the kingdom for Philip II. decided to move their quarters to his residence; thereupon, finding his protest against this arbitrary resolution unheeded, he set fire to his house, and to escape the consequences of his courageous act had to leave Portugal. Going to Madrid, he not only escaped any penalty, owing no doubt to his position and influence at the Spanish court, but was able to pursue his literary studies in peace and to publish the works of his friend Jaime Falcão (Madrid, 1600). Nothing is known of how he passed the next thirteen years, though there is a tradition that, at the instance of a brother resident in Panama, who held out the prospect of large commercial gains, he spent some time in America. It is said that fortune was unpropitious, and that this, together with the news of the death of his only child, D. Anna de Noronha, caused his return home about 1604. In 1613 he and his wife agreed to a separation, and he took the Dominican habit in the convent of Bemfica, while D. Magdalena entered the convent of the Sacramento at Alcantara. According to an old writer, the motive for their act was the news, brought by a pilgrim from Palestine that D. Magdalena's first husband had survived the battle of Alcacer, in which he was supposed to have fallen, and still lived; Garrett has immortalized the legend in his play *Frei Luiz de Sousa*. The story, however, deserves no credit, and a more natural explanation is that the pair took their resolution to leave the world for the cloister from motives of piety, though in the case of Manoel the captivity of his country and the loss of his daughter may have been contributory causes. He made his profession on the 8th of September 1614, and took the name by which he is known as a writer, Frei Luiz de Sousa. In 1616, on the death of Frei Luiz Cacegas, another notable Dominican who had collected materials for a history of the order and for a life of the famous archbishop of Braga, D. Frei Bartholomew of the Martyrs, the task of writing these books was confided to Frei Luiz. The *Life of the Archbishop* appeared in 1619, and the first part of the *Chronicle of St Dominic* in 1623, while the second and third parts appeared posthumously in 1662 and 1678; in addition he wrote, by order of the government, the *Annals of D. John III.*, which were published by Herculano in 1846. After a life of about nineteen years spent in religion, he died in 1632, leaving behind him a memory of strict observance and personal holiness.

The *Chronicle of St Dominic* and the *Life of the Archbishop* have the defect of most monastic writings—they relate for the most part only the good, and exaggerate it without scruple, and they admit all sorts of prodigies, so long as these tend to increase devotion. Briefly, these books are panegyrics, written for edification, and are not histories at all in the critical sense of the word. Their order and arrangement, however, are admirable, and the lucid, polished style, purity of diction, and simple, vivid descriptions, entitle Frei Luiz de Sousa to rank as a great prose-writer. His metaphors are well chosen, and he employs on appropriate occasions familiar terms and locutions, and makes full use of those charming diminutives in which the Portuguese language is rich. His prose is characterized by elegance, sweetness and strength, and is remarkably free from the affectations and false rhetoric that characterized the age. In addition to his other gifts, Frei Luiz de Sousa was a good Latin poet. There are many editions of the *Life of the Archbishop*, and it appeared in French (Paris, 1663, 1679 and 1825), in Italian (Rome, 1727–1728), in Spanish (Madrid, 1645 and 1727) and in English

(London, 1890). The *Historia de S. Domingos* may be read in a modern edition (6 vols., Lisbon, 1866).

SOUSLIK, or SUSLIK, the vernacular name of a European burrowing rodent mammal, nearly allied to the marmots, but of much smaller size and of more slender and squirrel-like build (see RODENTIA). The species, *Spermophilus* (or *Citillus*) *citillus*, is rather smaller than an ordinary squirrel, with minute ears, and the tail reduced to a stump of less than an inch in length. The general colour of the upper parts is yellowish grey, with or without a rusty tinge, which is, however, always noticeable on the head; while the underparts are lighter. The range of this species embraces south-east Europe, from southern Germany, Austria and Hungary to the south of Russia. Farther east it is replaced by more or less nearly allied species; while other species extend the range of the genus across central and northern Asia, and thence, on the other side of Bering Strait, all through North America, where these rodents are commonly known as gophers. Many of the species have medium or even long tails, while some are nearly double the size of the typical representative of the group. All, however, have large cheek-pouches, whence the name of pouched marmots, by which they are sometimes called; and they have the first front-toe rudimentary, as in marmots. They are divided into several subgeneric groups. One of the most striking American species is the striped gopher, *S.* (*Ictidomys*) *tridecemlineatus*, which is marked on each side with seven yellow stripes, between which are rows of yellow spots on a dark ground. The common souslik lives in dry, treeless plains, especially on sandy or clayey soil, and is never found either in forests or on swampy ground. It forms burrows, often 6 or 8 ft. deep, in which food is stored up and the winter sleep takes place. Each burrow has but one entrance, which is closed up when winter approaches; a second hole, however, being previously driven from the sleeping place to within a short distance of the surface of the ground. This second hole is opened the next year, and used as the ordinary entrance, so that the number of closed up holes round a burrow gives an indication of the length of time that it has been occupied. Sousliks feed on roots, seeds and berries, and occasionally on animal food, preying on eggs, small birds and mice. They bring forth in the spring from four to eight young ones, which, if taken early, may be easily tamed. Sousliks are eaten by the inhabitants of the Russian steppes, who consider their flesh an especial delicacy. (R. L.*)

SOUTANE, the French term adopted into English for a cassock especially used for the general daily dress worn by the secular Roman clergy in France, Italy, Spain and Portugal. The Med. Lat. *subtaneus*, adapted in O. Fr. as *sotane*, in Span. and Ital. as *sotana*, and Port. as *sotaina*, meant an under-skirt, and is formed from *subtus*, beneath, *sub*, under. (See CASSOCK.)

SOUTH, ROBERT (1634–1716), English divine, was born at Hackney, Middlesex, in September 1634. He was educated at Westminster school and at Christ Church, Oxford. Before taking orders in 1658 he was in the habit of preaching as the champion of Calvinism against Socinianism and Arminianism. He also at this time showed a leaning to Presbyterianism, but on the approach of the Restoration his views on church government underwent a change; indeed, he was always regarded as a time-server, though by no means a self-seeker. On the 10th of August 1660 he was chosen public orator of the university, and in 1661 domestic chaplain to Lord Clarendon. In March 1663 he was made prebendary of Westminster, and shortly afterwards he received from his university the degree of D.D. In 1667 he became chaplain to the duke of York. He was a zealous advocate of the doctrine of passive obedience, and strongly opposed the Toleration Act, declaiming in unmeasured terms against the various Nonconformist sects. In 1676 he was appointed chaplain to Lawrence Hyde (afterwards earl of Rochester), ambassador-extraordinary to the king of Poland, and of his visit he sent an interesting account to Edward Pococke in a letter, dated Dantzic, 16th December, 1677, which was printed along with South's *Posthumous Works* in 1717. In 1678 he was presented to the rectory of Islip, Oxfordshire. Owing, it is said, to a personal grudge, South in 1693 published with transparent anonymity *Animadversions on Dr Sherlock's Book, entitled a Vindication of the Holy and Ever Blessed Trinity*, in which the views of William Sherlock (*q.v.*) were attacked with much sarcastic bitterness. Sherlock, in answer, published a *Defence* in 1694, to which South replied in *Tritheism Charged upon Dr Sherlock's New Notion of the Trinity, and the Charge Made Good*. The controversy was carried by the rival parties into the pulpit, and occasioned such keen feeling that the king interposed to stop it. During the greater part of the reign of Anne South remained comparatively quiet, but in 1710 he ranked himself among the partisans of Sacheverell. He declined the see of Rochester and the deanery of Westminster in 1713. He died on the 8th of July 1716, and was buried in Westminster Abbey.

South had a vigorous style and his sermons were marked by homely and humorous appeal. His wit generally inclines towards sarcasm, and it was probably the knowledge of his quarrelsome temperament that prevented his promotion to a bishopric. He was noted for the extent of his charities. He published a large number of single sermons, and they appeared in a collected form in 1692 in six volumes, reaching a second edition in his lifetime in 1715. There have been several later issues; one in two volumes, with a memoir (Bohn, 1845). His *Opera posthuma latina*, including his will, his Latin poems, and his orations while public orator, with memoirs of his life, appeared in 1717. An edition of his works in 7 vols. was published at Oxford in 1823, another in 5 vols. in 1842. See also W. C. Lake, *Classic Preachers of the English Church* (1st series, 1877). The contemporary notice of South by Anthony Wood in his *Athenae* is strongly hostile, said to be due to a jest made by South at Wood's expense.

SOUTH AFRICA. As a geographical unit South Africa is usually held to be that part of the continent south of the middle course of the Zambezi. The present article (1) deals with that part of Africa as a whole, (2) outlines the constitution of the British possessions forming the Union of South Africa, and (3) summarizes the history of the country from the time of its discovery by Europeans.

I.—GENERAL FEATURES

In the geographical sense stated South Africa lies between 16° and 35° S. and 12° and 36° E., narrows from 1600 m. from west to east along its northern border to some 600 m. of coast facing south. Its greatest length south-west to north-east is also about 1600 m. It has an area of about 1,333,000 sq. m. It comprises the Union of South Africa (*i.e.* the provinces of the Cape of Good Hope, Natal, with Zululand, the Orange Free State and the Transvaal); Basutoland, Bechuanaland, Swaziland and Southern Rhodesia, all British possessions; German South-West Africa, and the southern part of Portuguese East Africa. By some writers Northern Rhodesia is included in South Africa, but that district belongs more accurately to the central portion of the continent. Other writers confine the term to the British possessions south of the Zambezi, but in this case British South Africa is the proper designation. South African standard time, adopted in 1903, is that of 30° E., or two hours in advance of Greenwich.

Physical Features.—There is a marked uniformity in physical features throughout South Africa. The coast line, from the mouth of the Kunene on the west to the delta of the Zambezi on the east, is little indented and contains only two sheltered natural harbours of any size—Saldanha Bay on the west and Delagoa Bay on the east. At Port Natal, however, the removal of the sand bar at its entrance has made available a third magnificent harbour, while at Table Bay (Cape Town) and at other places ports have been constructed. South Africa presents, however, a solid land mass without peninsulas of any size or any large islands off its coasts. Moreover, behind the low-lying coast-lands, which extend in general from 50 to 250 m. inland, rise ramparts of hills shutting off the interior. This conformation of the country has been a powerful influence in determining its history and development. Here and there the mountains, which run in lines parallel to the coast, approach close to the sea, as at Table Bay. In the south-east, in the Drakensberg, they attain heights of 10,000 to 11,000 ft., elsewhere the highest points are between 8000 and 9000 ft. They form terrace-like steps leading to a vast tableland (covering about 900,000 sq. m.) with a mean elevation of 4000 ft., the highest part of the plateau —the High Veld of the Transvaal—being fully 6000 ft. above the sea. In its southern part the plateau has a general tilt to the west, in the north it tilts eastward. This tilt determines the hydrographical system. In the south the drainage is to the Atlantic, chiefly through the Orange River, in the north to the Indian Ocean through the Zambezi, Limpopo and other streams. A large number of smaller rivers rise on the outer slopes of the mountain ramparts and flow direct to the sea. In consequence of their great slope and the intermittent supply of water the rivers—except the Zambezi—are unnavigable save for a few miles from their mouths. The central part of the interior plateau, covering some 120,000 sq. m., is arid and is known as the Kalahari Desert. The western region, both plateau and coastlands, specially that part north of the Orange, is largely semi or wholly desert, while in the Cape province the terrace lands below the interior plateau are likewise arid, as is signified by their Hottentot name *karusa* (Karroo). The southern and eastern coastlands, owing to different climatic conditions (see *infra*) are very fertile.

The geological structure is remarkably uniform, the plateau consisting mainly of sedimentary deposits resting on crystalline rocks. The Karroo system (sandstones and marls) covers immense areas (see AFRICA, § *Geology*). Intrusive dikes—locally known as ironstone—by preventing erosion are often the cause of the flat-topped hills which are a common feature of the landscape. The Witwatersrand series of the Transvaal includes auriferous conglomerates which have been worked since 1886 and constitute the richest gold-mines in the world. The diamondiferous areas at Kimberley and in the Pretoria district are likewise the richest known. Coal beds are widely distributed in the eastern districts while there are large copper deposits in the west, both at the Cape and in German territory.

Climate.—The general characteristics of the climate are determined more by the physical conformation of the land than its proximity to the equator. The eastern escarpments (the Drakensberg, &c.) of the plateau intercept the rain-bearing winds from the Indian Ocean, so that over the greater part of the interior the rainfall is slight (5 to 24 in.). This, added to the elevation of the land, makes the climate in general dry, bracing and suitable for Europeans, notwithstanding that the northern part is within the tropics. Temperature is high, the mean yearly average lying between 60° and 70° F. Only along the south-eastern coast and in some of the river valleys is the climate of a markedly tropical character; here the rainfall rises to 50 in. a year and the coast is washed by the warm Mozambique current. The Cape peninsula and the western coast receive the cold currents from the Antarctic regions. Except in southern and western Cape Colony and along the Atlantic coast, summer is the rainy season.

Flora and Fauna.—In consequence of the deficient rainfall over the greater part of the country the flora is not luxuriant and there are no large forests. Coarse grasses are the characteristic vegetation of the tableland. On the plains where grasses cannot find sufficient moisture their place is taken by "bush," composed mainly of stunted mimosas, acacias, euphorbia, wild pomegranate, bitter aloes and herbaceous plants. Forest patches are found in the kloofs and seaward sides of the mountains; willows often border the water-courses; heaths and bulbous plants are common in some areas. In the semi-tropical regions south-east of the Drakensberg, *i.e.* the coastlands of Natal and Portuguese East Africa, the vegetation is abundant, and mangroves, palms, baobab and bombax trees flourish. Here, and also in the upper Limpopo valley, cotton, tobacco, and rubber vines are found. Among the timber trees are species of pine, cedar, ebony, ironwood, stinkwood and sneezewood. Flowering plants include numerous species of terrestrial orchids, the so-called arum lily (*Richardia Africana*), common in low-lying moist land, and the white everlasting flower, found abundantly in some regions of Cape Colony. Of non-indigenous flora are the oak, poplar, bluegum, the Australian wattle, the vine, and almost every variety of fruit tree and European vegetables. In suitable regions tea, coffee, sugar and rice, as well as tobacco and cotton, are cultivated. In the western districts of the Cape viticulture is largely followed. The cereal most grown is maize (known in South Africa as mealies); kaffir corn, wheat, barley and oats are also largely cultivated. The soil is everywhere rich, but the lack of perennial water and the absence of irrigation works on a large scale retards agriculture. Most of the veld is divided into huge farms devoted to the rearing of cattle, sheep, goats and horses. On the Karroo are numerous ostrich farms. Lucerne is very largely grown as fodder for the cattle.

The native fauna was formerly very rich in big game, a fact sufficiently testified by the names given by the early European settlers to mountains and streams. The lion, elephant, rhinoceros, hippopotamus, giraffe, buffalo, quagga, zebra and other large animals were, however, during the 18th and 19th centuries driven out of the more southern regions (though a few elephants and buffaloes, now carefully preserved, are still found at the Cape), the quagga being totally exterminated. In the Kalahari and in the eastern lowlands (from Zululand to the Zambezi delta) most of these animals are still found, as well as the eland, wildebeest and gemsbok. The leopard (called a tiger in South Africa) is still fairly common in all mountainous regions. Spotted hyenas and jackals are also numerous. The kudu is now the most common of the larger antelopes, the duiker and klipspringer are among the smaller antelopes still existing in large numbers. Baboons are common in some districts. Birds include the ostrich, great kori bustard, the eagle, vulture, hawk and crane, francolin, golden cuckoo, loorie, scarlet and yellow finches, kingfishers, parrots (in the eastern regions), pelicans and flamingoes. There are thirty varieties of snakes. Locusts are conspicuous among the common plagues of the country. In Rhodesia and on the east coast the tsetse fly is found and termites are widely distributed.

Inhabitants.—The aborigines of South Africa are represented by the Bushmen and Hottentots, now found in any racial purity only in the Kalahari and in the southern part of German South-West Africa. All the other natives, popularly called Kaffirs, are members of the Bantu-negroid family, of whom they here form three distinct branches: (1) the *Zulu-Xosas*, originally confined to the south-east seaboard between Delagoa Bay and the Great Fish River, but later (19th century) spread by conquest over Gazaland, parts of the Transvaal, and Rhodesia (Matabeleland), (2) the *Bechuanas*, with the kindred *Basutos*, on the continental plateau from the Orange to the Zambezi, and ranging westwards over the Kalahari desert and the Lake Ngami region; (3) the *Ova-Herero* and *Ova-Mpo*, confined to German South-West Africa between Walfish Bay and the Kunene River.

All these mixed Bantu peoples are immigrants at various periods from beyond the Zambezi. The Bechuanas, who occupy by far the largest domain, and preserve the totemic tribal system, were probably the first arrivals from the north or the north-sea coastlands. As early, probably, as the 8th century A.D. Arabs had formed a settlement on the coast at Sofala, 130 m. south of the mouth of the Zambezi, but they got no further south nor do they appear to have penetrated inland, though they traded for gold and other articles with the inhabitants of the northern part of the plateau—the builders of the zimbabwes and other ruins in what is now Rhodesia (*q.v.*) The Asiatic inhabitants of South Africa of the present day are mainly Indian

Population (1904).

[1] Estimates. [2] 1907.

coolies brought to Natal since 1860. The white races represented are mainly Dutch and British; colonization by European races dating from the 17th century. There are a few thousand Germans and Portuguese, chiefly in the territories belonging to their respective countries. The table on p. 464 shows the inhabitants, white and coloured, in the different territories into which South Africa is divided, and also the area of these territories.

It will be seen that the population is sparse, less than 6½ persons per square mile. (Excluding the Bechuanaland Protectorate and German South-West Africa, which contain very large desert areas, the population is slightly over 7 per square mile.) In British South Africa the coloured races are nearly five times as numerous as the whites. The great majority of the coloured inhabitants are Bantus of pure blood, but the total coloured population includes in the Cape province 298,334 persons of mixed blood (chiefly white and Hottentot) and in Natal 100,918 Asiatics. Save in the German colony the official returns do not discriminate between the nationality of the white inhabitants. Those of British and Dutch origin are probably about equal in numbers, but a very large proportion of the British inhabitants live in the towns, the country population being in most districts predominantly Dutch. The chief cities are Cape Town (pop. 1904, 77,668), Port Elizabeth (32,959), East London (25,220) and Kimberley (34,331) in the Cape province; Durban (67,847) in Natal; Johannesburg (155,642) and Pretoria (36,839) in the Transvaal; and Bloemfontein (33,883) in the Orange Free State. Salisbury and Buluwayo are the chief towns in Southern Rhodesia. The only town of any size outside the British possession is Lourenço Marques (Pop. 1907, 9849) in Delagoa Bay.

Economic Condition.—Originally regarded by Europeans merely as a convenient dépôt for ships on their way to India, the wealth of South Africa for long consisted in its agricultural and pastoral resources. Mealies and wheat were the principal crops. Wool, mohair and ostrich feathers were the chief exports, the only mineral exported being copper (from the Namaqualand mines). The opening up of the diamond mines at Kimberley (1870) followed (1886) by the discovery of the Witwatersrand goldfields completely revolutionized the economic situation and profoundly modified the history of the country. They led, among other things, to the improvement of ports and the building of railways, so that by the close of the first decade of the 20th century the reproach of inaccessibility from which South Africa had suffered was no longer true. From the seaports of Cape Town, Port Elizabeth, East London, Durban, Lourenço Marques and Beira railway lines run to Kimberley, Bloemfontein, Johannesburg and Pretoria, while a trunk line extends north from Kimberley through Rhodesia (in which gold mining began on an extensive scale in 1898) and across the Zambezi below the Victoria Falls into the Congo basin, where it serves the Katanga mineral area. The distance from Cape Town to Katanga is over 2100 miles. The German territory is also provided with railways, intended eventually to link with the British systems. The standard gauge is 3 ft. 6 in. and in 1910 some 12,000 m. of railway were open. In nearly every instance the railways are state owned. While gold and diamond mining continue the greatest of South African industries other sources of wealth have been added. In the Cape, Natal and the Transvaal coal mining is largely developed; in the Transvaal and the Cape tobacco is grown extensively; sugar, tea and other tropical and sub-tropical produce are largely cultivated in Natal and the Portuguese territory, and, since 1905, mealies have become an important article of export. There are few manufactures; among the chief are the making of wine and brandy in the Cape province, and flour-milling. Cattle and mealies constitute the most valuable possessions of the natives. The imports are of a general nature, textiles and food-stuffs being the most important.

Irrigation.—The scanty rainfall in many parts of South Africa and its unequal distribution necessitates a system of artificial irrigation unless much of the land be allowed to remain uncultivated. But in many regions the soil is deficient in phosphates and nitrates, and large irrigation works can be profitable only in districts where the soil is exceptionally fertile. Before 1877 little was done to make use of the water resources of the country. In that year the Cape legislature provided for the constitution of irrigation boards. Later boring operations were undertaken by the government, and the advice of engineers acquainted with Egyptian and Indian irrigation works sought. A report was drawn up by Sir (then Mr) Wm. Willcocks in 1901 in which he estimated that there were in the Cape, Orange Free State and the Transvaal, 3,000,000 acres which could be brought under irrigation at a cost of about £30,000,000. The value of the land, in its arid condition almost nil, when irrigated he placed at some £100,000,000. None of the South African governments was, however, then in a position to undertake large works. At the Cape the census of 1904 gave 415,688 acres as the area under irrigation, an increase of 105,827 acres since 1891. In the Robertson district a canal (completed in 1904) 21 m. long took off from the Breede River and fertilized a large area, with the result that Robertson ranks as the second richest district in the province. Over the Karroo and other arid regions some 10,000 boreholes had been sunk to depths varying from 50 to 500 ft., their yield being 60,000,000 gallons a year. The value of land under artesian well irrigation (*e.g.* in the Graaff Reinet district) has increased from 20s. to £200 per morgen. More important, however, are the supplies to be derived from the control of flood water, millions of cubic feet of the best soil being annually washed into the sea. The Boer governments had done little to promote irrigation, but during 1905–1907 a strong intercolonial commission investigated the subject as it affected the Transvaal and Orange Free State, and their final report, issued at Pretoria in 1908, contains full particulars as to the irrigation possibilities in those provinces. At least 350,000 acres in the Transvaal could be remuneratively irrigated, and a proportionally large area in the Orange province. In Natal an act of 1904 gave power to the government to forward irrigation schemes. Under that act the Winterton Irrigation Settlement (18,000 acres) was formed on the upper Tugela. In 1909 an irrigation congress representative of all the governments of British South Africa was held at Robertson, in the Cape province.

Commerce.—All the British states and territories are members of postal, telegraphic and customs unions. The customs are of a protective character, while there is a rebate on goods from Great Britain and British possessions[1] (see below, *History*). There is internal free trade throughout the Union of South Africa. The customs tariff in the Portuguese possessions is of a highly protective nature; goods coming from Portugal pay one-tenth of the dues levied on foreign goods. In German South-West Africa no discrimination is made as to the country of origin of imports.

A South African Customs Statistical Bureau, which deals with the external trade of British South Africa,[2] was established in July 1905. The statistics issued by the bureau showed a total volume of trade in 1905 of £72,910,000 made up as follows: Imports £29,859,000 (including £4,208,000 received through Portuguese ports); exports £43,050,000. Of this amount £25,644,000 was put as the value of raw gold exported, and £9,257,000 as the value of the diamonds shipped. Only £414,000 worth of goods was exported via Portuguese ports. For 1907 the figures were: Value of total trade £74,153,000; imports £25,920,000, exports £48,233,000. Goods valued at £4,036,377 received through Portuguese ports are included in the imports, and goods valued at £507,000 shipped at Portuguese ports in the exports. The value of raw gold exported in 1907 was £29,510,000, of diamonds £8,973,000. In 1908 the figures were: Total trade £70,093,000; imports £24,438,000 (including £4,641,000 via Portuguese ports); exports £45,655,000 (including £513,000 from Portuguese ports). The raw gold exported was worth £32,047,000 but the export of diamonds fell to £4,796,000. In 1909 the value of the imports into British South Africa was returned at £29,842,000; the value of the exports at £51,151,000.[3] Of the imports over £16,850,000 came from the United Kingdom, over £2,240,000 from Australia, £2,450,000 from Germany, and £2,195,000 from the United States. Of the exports raw gold was valued at £33,303,000, diamonds at £6,370,000, wool at £3,728,000 and ostrich feathers at £2,091,000. The value of the imports through Delagoa Bay and other Portuguese ports was £6,795,000, the exports from Portuguese ports were valued at slightly over £500,000. In the four years the imports from the United Kingdom were about 58%, from other parts of the empire 13%. Of the exports the United Kingdom took some 95%; a considerable quantity of South African produce, especially wool, shipped to England ultimately however finds its way to other countries. Next to Great Britain the countries doing most trade with South Africa are Australia and New Zealand, Germany, the United States, Canada, Brazil, India, Belgium, Holland and France.

Religion.—The great majority of the white inhabitants are Protestants. Most of those of Dutch descent are members of the Dutch Reformed Church (*Nederduitsch Hervormde Kerk*), the state church of the early Cape colonists, or of churches formed by dissentient members of the original church such as the *Gereformeerde Kerk* (the "Dopper" Church), a branch (introduced in 1858) of the Separatist Reformed Church of Holland. These churches are Calvinistic in doctrine and Presbyterian in organization. Until 1843 the Cape synod was controlled by government commissioners; it was then given power to regulate its own internal affairs. There are separate synods with independent authority for the congregations of the Dutch Reformed Churches in the Cape, Orange Free State and Transvaal provinces. The Doppers ("roundheads") and other dissentient bodies have also separate synods. Besides these churches there are a number of Lutheran congregations among the Dutch speaking population.

The South Africans of British descent are divided, mainly, into Anglicans, Wesleyans and Presbyterians. The Baptists and Congregationalists are smaller bodies. All form independent churches in communion with the mother churches in Great Britain. The oldest established is that of the Presbyterians. The Anglican

[1] The total amount rebated in 1908 was £430,017.

[2] Including North-West Rhodesia.

[3] For the six months January to June 1910 the figures were: imports £14,770,000; exports £24,442,000.

organization dates from 1847. Being declared by judicial decision in 1863 a voluntary body, the Anglicans formed "The Church of the Province of South Africa." It is divided into the dioceses of Cape Town, Graham's Town, Maritzburg (Natal), Kaffraria, Bloemfontein, Pretoria, Zululand, Mashonaland and Lebombo. The last-named diocese is that part of Portuguese East Africa south of the Sabi river; the Mashonaland diocese includes the Portuguese territory between the Sabi and the Zambezi. German South-West Africa is not included in the Anglican organization. The metropolitan is the archbishop of Cape Town. The constitution of the church was drawn up at a provincial synod in 1870. It accepts the doctrines of the Church of England, but acknowledges none save its own ecclesiastical tribunals, or such other tribunal as may be accepted by the provincial synod—in other words it rejects the authority of the English privy council. Bishop Colenso of Natal and other Anglicans did not accept the authority of the provincial synod, regarding themselves as in all respects members of the Church of England. This was, especially in Natal, the cause of prolonged controversy among the members of the Anglican community. By 1901, however, the majority of the "Church of England party" were represented in the provincial synod. Nevertheless the temporalities of this party remained in the hands of curators and not in the possession of the provincial church. In 1910 the practical amalgamation of the two bodies was effected (see further NATAL).

The Roman Catholics are a comparatively small body; the majority of their adherents are found in the Cape and Natal. At the head of their organizations are vicars-apostolic for the Cape (eastern district), the Cape (western district), Natal, Orange River, Kimberley and the Transvaal, and prefects-apostolic for Basutoland and Zambezi (or Rhodesia).

Missions to Natives. All the churches maintain missions to the natives. The first to enter the field were the Jesuits and Dominicans, who laboured on the south-east coast and among the subjects of the monomotapa (see PORTUGUESE EAST AFRICA). Their work lasted from about 1560 to 1760, but it has left little trace. The early modern missions were all Protestant. A Moravian mission to the Hottentots was begun in 1737, continued to 1744 and was re-established—against the wishes of the colonists—in 1792. Before the close of the century the London Missionary Society entered the field. The work of this society's agents has had a greater influence on the history of South Africa than that of any other religious body save the Dutch Reformed Church. Next in order came the Wesleyans and the Glasgow Missionary Society (Presbyterian), the last-named society founding in 1824 the station of Lovedale—now the most important institution in South Africa in connexion with native missions. In 1829 the Paris Evangelical Society (whose agents have laboured chiefly in Basuto and Barotse lands) sent out their first missionaries, who were closely followed by the agents of other societies (see MISSIONS). The Roman Catholics entered the field later on. By the end of the 19th century fully 5% of the total native population professed Christianity.

The Jews form a small but influential community. There are some thousands of Mahommedans in the Cape (chiefly Malays) and larger numbers in Natal, where there is also a large Hindu population. At Lourenço Marques the Chinese colony has its own temple and religious services.

Law.[1]—The basis of the common law of British South Africa is the Roman-Dutch law as it existed in Holland at the end of the 18th century. This was simply the old Roman jurisprudence embodied in the legislation of Justinian, modified by custom and legislative decrees during the course of the centuries which witnessed the growth of civilization in Europe; and it is to all intents and purposes the jurisprudence which was the foundation of the Code Napoléon. It was in part closely akin to the "modern Roman law" which is practised widely over the continent of Europe, and even in Scotland, at the present day. The authorities upon the common law in South Africa are: the Dutch commentators upon the civil law, the statute law of Holland, the decisions of the Dutch courts, and, failing these, the *corpus juris civilis* itself.

In the period which has elapsed since the establishment of British rule at the Cape the law has been considerably modified and altered, both by legislation and by judicial decisions, and it is not too much to say that at the present time there exists hardly any material difference in principle over the greater part of the field of jurisprudence between the law of England and the law of South Africa. The law of contracts, the law of torts, the mercantile law, the law relating to shipping and insurance, not to mention other subjects, are practically identical with those of England; and even the criminal law is virtually the same, though the greater elasticity of the civil jurisprudence allows fewer opportunities for the escape of malefactors, notably in cases of fraud or falsity in any form, than exist under the law of England. The constitution of the courts is based on the example of the English judiciary, and the rules of evidence and procedure are practically the same in both criminal and civil cases as in England. All serious cases of crime are tried before a judge and jury, with the same formalities and safeguards as in England, while minor offences are dealt with by stipendiary magistrates possessing a limited statutory jurisdiction. In criminal cases it is necessary for the jury to find a unanimous verdict. In civil cases either party may demand a jury, a privilege which is seldom exercised; but in a civil case the verdict of the majority of jurors prevails.

The most marked difference between the English and South African systems of law is, as might be expected, to be found in the law relating to real property. In South Africa there is a rigid and universal application of the principle of registration. The title to land is registered, in all cases; and so, with a few exceptions, is every servitude or easement, mortgage or charge, upon land. With regard to the devolution of property upon death, it may be remarked that the law of intestate succession applies equally to real and personal estate, there being no law of primogeniture. The rules of distribution in intestacy differ, however, very considerably from those established in England. There is absolute freedom of testamentary disposition in the Cape province and in some other parts of South Africa. The effect of marriage upon the property of the spouses is, by the Roman-Dutch law and in the absence of any ante-nuptial contract to the contrary, to bring about a complete community of property, virtually a universal partnership between husband and wife, subject to the sole and absolute control of the husband while the marriage lasts. The courts have, however, the right to interfere for the protection of the wife in case of any flagrant abuse of the power thus vested in the husband. Ante-nuptial agreements may be of any nature the parties may choose. Such agreements must in all cases be publicly registered. Upon the dissolution of a marriage in community of property, or in the event of a judicial separation *a communione bonorum*, the property of the spouses is divided as upon the liquidation of a partnership. It is not necessary here to refer particularly to certain exceptions to this general rule in cases of divorce.

By the common law gifts between husband and wife during marriage are void as against creditors. This rule cannot be evaded even by ante-nuptial agreement. By the statute law of Natal post-nuptial agreements between spouses are permitted under certain conditions, to which it is not possible now to refer at length. Divorce is granted to either spouse for either adultery or malicious desertion, the distinctions established by the English law between husband and wife in respect of divorce being disregarded.

Language.—The languages spoken in South Africa by the inhabitants of European descent are English and Dutch, the latter chiefly in the form of a patois colloquially known as the Taal. (German and Portuguese are spoken in the possessions of those countries, but a knowledge of English or Dutch is frequent even in those territories.) The history of the Dutch language in South Africa is intimately bound up with the history of the South African Dutch people. The basis of the language as spoken to-day is that 17th-century Dutch of Holland which the first settlers brought to the country; and although the Dutch of Holland and the Dutch of South Africa differ very widely to-day, Cape Dutch differs less widely from the Dutch language of the 17th century than from the modern Dutch of Holland. The tongue of the vast majority of the Dutch-speaking inhabitants may thus be said to be a degenerate dialect of the 17th-century Dutch of Holland, with a very limited vocabulary. The limiting of the vocabulary is due to two reasons. In the first place, the early settlers were drawn principally from the peasant class, being chiefly discharged soldiers and sailors; and, further, when once settled, the necessity for making the language intelligible to the natives by whom the settlers were surrounded led

[1] For the sections here incorporated on South African law and language we are indebted to the late J. W. Leonard, K.C. (d. 1909), twice attorney-general of Cape Colony.

to a still further simplification of speech structure and curtailment of the vocabulary. There thus grew up an ungrammatical dialect of Dutch, suited only to the most ordinary requirements of the everyday life of a rural population. It became a language with neither a syntax nor a literature. At the same time it remained in character almost entirely Dutch, no French—in spite of the incorporation into the population of the Huguenot emigrants—and only a few Malay words finding a place in the Taal. But side by side with this language of everyday life a purer form of Dutch has continued to exist and find its uses under certain conditions. It must be borne in mind that the Boers of every grade have always been more or less sedulously instructed in religious subjects, at all events to the extent required to fit them for formal membership of their church, and in all their wanderings they have usually been attended by their pastors. The Dutch Bible and Catechism are written in pure Dutch. The language of the Dutch Bible is as majestic as that of the English version. Moreover, the services of the Church have always been conducted in grammatical though simple Dutch; and the clergy, in their intercourse with the people, have as a general rule abstained from conversing in the ordinary dialect. The Boer thus has but slight difficulty in reading and understanding pure Dutch. Under the influence of Africander nationalism strenuous efforts have been made to teach the language in the schools throughout the greater part of South Africa. In the Transvaal and Orange Free State education was imparted almost exclusively in Dutch. All public business in the government offices and law courts was conducted in the language, and the Transvaal at the time of its annexation by Great Britain was being gradually inundated by officials, railway servants and others introduced from Holland, who spoke modern Dutch. Officially throughout the Union of South Africa both languages are now on a footing of equality.

Throughout South Africa a number of words, mainly Dutch, are in general use by the English-speaking inhabitants and also, to a considerable extent, among the natives. The most common of these words, with their English meanings, are here set forth. When not otherwise stated the words are of Dutch origin:—

Assegai	a spear used by the Kaffir tribes; a word adopted from the Portuguese, but of Berber origin.
Boschveld . . .	a plain or open stretch of country covered with thin wood or bush. Often written bushveld.
Bywoners . . .	(literally witnesses) "poor whites," the name given by the Boers to the landless whites, hangers-on at farms, &c.
Daal	valley.
Dorp	village.
Drift	ford (a "Taal" word).
Ervan (sing. erf) .	plots of land.
Fontein	fountain, spring.
Hoek	corner, angle, hook. Common in place-names.
Inspan	to harness.
Kaffir	(Arabic for unbeliever [in Islam]) a native of Bantu stock; more loosely any native.
Karroo	any arid district; now the name of definite regions (from the Hottentot).
Kloof	fissure or crevice, hence a ravine or narrow valley.
Kop	(literally head) a hill, generally rounded. Flat-topped hills are usually called tafel (table) or plat (flat) bergs.
Kopje	a little hill; the name given to the isolated *pointed* hills which are a characteristic feature of the plains of South Africa.
Kraal	an enclosure, hence a native village. Probably from the Portuguese.
Krantz (or Kranz) .	an overhanging wall of rock, hence a steep cliff, a precipice. A "Taal" word derived from the Dutch *krans*, a wreath, chaplet or cornice.
Nek	literally neck } mountain passes or passes
Poort	literally gate } between mountains.
Rand	border, edge, hence a low and usually round range of hills.
Ruggens . . .	ridges, applied to undulating slopes or unirrigated hilly country.
Slim	cunning, clever, adroit.
Sluit	(Dutch *sloot*) ditch, gutter, small stream.
Spruit	(literally shoot, *spruiten*, to spring up), stream, small river. The name given to intermittent streams liable to sudden freshets.
Stoep	(literally a step), the name given to the platform or veranda of a house. The stoep is shaded by a roof and is a favourite rendezvous for the household and for visitors. Formerly all South African houses had stoeps, but in the central parts of the larger towns the buildings are now without verandas.
Trek	(literally, pull, tug, *trekken*, to draw or pull), to leave a place, to take a journey; also the distance covered in a journey.
Veld	field. The name given to open plains and to the grass-covered plateaus of the interior.
Vlei	a hollow filled with water during rainy weather.
Uitspan	to unharness.
Uitlander . . .	outlander, *i.e.* a foreigner.

Among other Dutch words frequently used in place-names may be instanced: rhenoster (rhinoceros) olifant (elephant), mooi (pretty), modder (mud), klip (cliff), berg (mountain), burg or stad (town), zwart (black), klein (little), groote (great), breede (broad), nieuw (new), zuur (sour), bokke (buck).

A number of Dutch weights and measures are also in general use. They include: muid =3 bushels; morgen =2·11654 acres. A Cape rood equals 12·396 English feet, and a Cape ton contains 2000 ℔.

II.—Constitution of the Union of South Africa

In accordance with the provisions of an act of the British Parliament (South Africa Act 1909) Cape Colony, Natal, the Transvaal and Orange River colonies were united under one government in a legislative union under the British crown. The Union of South Africa, as the new state is named, was established on the 31st of May 1910. Upon its formation the colonies named became provinces of the Union. In the case of the Orange River colony its title was changed to Orange Free State province. The colonial legislatures were abolished, provincial councils, with strictly subordinate and delegated powers, were set up, and provincial administrators (local men) replaced the various governors. The history of the movement which led to unification is given in the following section. The main provisions of the constitution [1] are as follows:—

The Executive. The executive government of the Union is vested in the king and may be exercised by the sovereign in person. It is, however, administered by a governor-general, who holds office during the king's pleasure. The governor-general can dismiss ministers and dissolve parliament. He is empowered to dissolve both houses of the legislature simultaneously or the House of Assembly alone. He can perform no official act when beyond the territorial limits of the Union, but he can appoint a deputy to act for him during temporary absences. The governor-general is paid £10,000 a year out of the consolidated funds of the Union. He is advised by an executive council, whose members he nominates. The council must include the ministers of state; ministers administering departments of state may not exceed ten in number. Ministers cannot hold office for a longer period than three months unless they are or become members of either house of parliament. The control and administration of native affairs (which before the Union was, except at the Cape, largely in the hands of the colonial governors personally) is vested exclusively in the governor in council and to the same authority is entrusted all matters specially or differentially affecting Asiatics throughout the Union.

The Legislature. The legislative power is vested in a parliament consisting of the Sovereign, a Senate, and a House of Assembly. The Senate consists of 40 members, 8 representatives from each province, and 8 members nominated by the governor-general in council. Four of the nominated members are selected on the ground mainly of their thorough acquaintance with "the reasonable wants and wishes" of the coloured races in South Africa. The presence of both nominated and elected members in the Senate is a novel provision in the constitution of the upper chambers of British colonial legislatures. The senators chosen in 1910 hold office for ten years. After 1920 the Union parliament may make any alteration it sees fit in the constitution of the senate. A senator must be a British subject of European descent, must be thirty years old. be a parliamentary voter in one of the provinces, have lived for five years in the Union, and if an elected member be possessed of immovable property within the Union of the clear value of £500.

[1] For a detailed examination of the constitution and a comparison of it with the federal constitutions of Canada and Australia see "South African Union," by A. Berriedale Keith, in the *Journ. Soc. Comp. Legislation* for October 1909.

The House of Assembly consists (as originally constituted) of 121 members, elected by single-membered constituencies, each constituency containing as nearly as possible the same number of voters. Of these members the Cape Province returns 51, the Transvaal 36, and Natal and Orange Free State 17 each. As population increases the total number of members may be raised to 150. The seats allotted to each province are determined by its number of European male adults as ascertained by a quinquennial census, the quota for a constituency being obtained by dividing the total number of such adults in the Union as ascertained at the 1904 census by the number of members at the establishment of the Union. The commission charged with the delimitation of constituencies is permitted to vary the quota as much as 15% either way. Members of the House of Assembly must, like senators, be British subjects of European descent, they must be qualified to be registered as voters and have lived for five years within the Union. A general election must take place every five years, and all polls must be taken on the same day. There must be a session of parliament every year, so arranged that twelve months shall not elapse between the last day of one session and the first sitting of the next session.

The qualifications of parliamentary voters are those which existed in the several colonies at the establishment of the Union, save that "no member of His Majesty's regular forces on full pay" can be registered as a voter. As the franchise laws in the several colonies differed the qualifications of voters in the provinces differ also. In the Transvaal and Orange Free State provinces the franchise is restricted to white adult male British subjects. In neither province is there any property qualification, but a six months' residence before registration is required. In Natal (*q.v.*) there is a low property qualification. In that province coloured persons are not by name debarred from the franchise, but they are in practice excluded. In the Cape province, where there is also a low property qualification, no colour bar exists and there are a large number of Kaffir voters (see CAPE COLONY: *Constitution*). Parliament may alter the qualifications for the vote, but no law which would deprive coloured persons in the Cape province of the franchise can be effective "unless the bill be passed by both houses of parliament sitting together and at the third reading be agreed to by not less than two-thirds of the total number of members of both houses."

Save as subject, ultimately, to the British parliament the Union parliament is a sovereign body. The provinces have no original authority, possessing only such powers as are delegated to them by the parliament. In certain cases the governor-general must reserve the royal assent to bills, *e.g.* any bill abolishing the coloured vote in the Cape province. The king is given the power to disallow any law within a year of it having received the assent of the governor-general.

With regard to bills the two houses are not in a position of equality. Bills appropriating revenue or moneys, or imposing taxation, must originate in the House of Assembly and may not be amended by the Senate. If a bill passed by the Assembly has been twice rejected by the Senate, provision is made for a joint sitting of both houses, when members vote and decide upon the measure concerned as one body. In the case of a money bill rejected by the Senate a joint sitting to decide its fate may be held in the same session in which the Senate has failed to pass the bill. Every minister of state may sit and speak in either house, but can vote only in the house of which he is a member. Re-election is not necessary on the appointment of a member as a minister of state. Members of parliament are paid £400 a year, £3 being deducted from this allowance for every day's absence during the session.

The Judicature.

A Supreme Court of Judicature for South Africa was created at the establishment of the Union. The former Supreme, High and Circuit Courts of the several colonies then became provincial and local divisions of the Supreme Court of South Africa, which consists of two divisions, namely the Supreme Court and the Appellate Division. Appeals from the decisions of the provincial and local divisions of the court and from those of the High Court of southern Rhodesia, must be made to the appellate division of the Supreme Court. Unless special leave of the privy council be obtained there can be no appeal from the decisions of the Appellate Division, save in admiralty cases. This restriction of the power of appeal to the privy council is much greater than are the restrictions upon appeals from the Commonwealth of Australia, where appeals to the privy council lie by right from the several state Supreme Courts. The difference arises from the fact that the Commonwealth is a federation of states; whereas the Union of South Africa is but one state with but one Supreme Court. One result of this unification of the courts of South Africa is that any provincial or local division of the Supreme Court in which an action is begun can order its transference to another division if that course be deemed more convenient. Moreover the judgments of each provincial division can be registered and enforced in any other division. The administration of justice throughout the Union is vested in a minister of state who has all the powers of the attorney-generals of the several colonies at the time of the Union, save that power as to the prosecution of crimes is vested in each province in an official appointed by the governor-general in council and styled the attorney-general of the province.

General Provisions.

Among the general provisions of the constitution the most important is that both the English and Dutch languages are official languages of the Union and are treated on a footing of equality; all records of parliament, and all notices of general public importance or interest issued by the government of the Union must be in both languages. (Persons in the public service at the establishment of the Union cannot, however, be dispensed with because of lack of knowledge of either English or Dutch.) Other general provisions enact free trade throughout the Union, but the customs and excise leviable under the laws existing in any of the colonies at the establishment of Union remain in force unless parliament otherwise provides. All persons who had been naturalized in any of the colonies are naturalized throughout the Union. All rights and obligations under conventions and agreements which were binding on any of the colonies have devolved upon the Union.

The harbours of Cape Town, Port Elizabeth, East London and Durban are state owned, as are also nearly all the railways in the Union. All revenues derived from these services are paid into a separate fund. The administration of the railways, ports and harbours is entrusted to a board of not more than three commissioners (appointed by the governor-general in council) presided over by a minister of state. Each commissioner holds office for five years and may be reappointed. The board is directed to administer its service on business principles, due regard being had to agricultural and industrial development, &c., within the Union. So far as may be the total earnings are not to be more than are sufficient to meet necessary outlays.

Provincial Administration.—While the Union parliament has full power to make laws for the whole of the Union, to provincial councils have been delegated the immediate control of affairs relating solely to the provinces. The subjects delegated to the councils include direct taxation within the provinces for local revenue purposes, the borrowing of money (on the sole credit of the provinces) with the consent of the ministry; agriculture (within the limits defined by parliament) and municipal institutions, divisional councils, and other local institutions. The control of elementary education was also guaranteed to the provincial councils up to 1915, and thereafter until parliament otherwise provides.

The councils consist of not fewer than 25 members and not more than the number of members returned by the province to the House of Assembly. Each councillor represents a separate constituency, these constituencies, as far as possible, to be the same as the parliamentary constituencies. (In the Cape and Transvaal provinces they were the same in 1910; Natal and Orange Free State returning only 17 members to the House of Assembly, the parliamentary constituencies have been rearranged.) The qualifications for electors are the same as for parliament, and any person qualified to vote is qualified to be a member of the council. As in the Cape province coloured persons are qualified to vote, they are thus also qualified to be members of the provincial council. Any member of the provincial council who becomes a member of either House of Parliament thereupon ceases to be a member of such provincial council. Each provincial council continues for three years from the date of its first meeting and is not subject to dissolution save by effluxion of time.

The executive power in each province is invested in an officer appointed by the government and styled provincial administrator. He holds office for five years. The administrator is assisted by an executive committee of four persons elected from among its own members, or otherwise, by the provincial council on the proportional representation principle. The administrator and any other member of the executive committee, not being a member of the council, has the right to take part in the proceedings of the council, but has not the right to vote. The provincial councils have not the right to make laws, but ordinances, which must receive the assent of the governor-general in council before becoming valid. (F. R. C.)

III.—HISTORY

The history of South Africa is, almost entirely, that of its colonization by European races, of their conflicts with, and influence over, its native inhabitants, and of the struggle for supremacy between the British and Dutch settlers. The little that is known concerning the doings of the natives before the appearance of the white man belongs to the domain of ethnology rather than of history. When the Portuguese first reached the southern part of Africa there was but one place in it where a civilized race held sway. This was at Sofala, the most southerly post of the East African Arabs. From that port the Arabs traded for ivory, slaves and (principally) gold with Bantu peoples of the far interior—the Rhodesia of to-day. These natives, whose earliest existing buildings may go back to the time of the Norman Conquest, were in a higher state of development than the Bushmen and Hottentots living farther south. The part played by the various native races in modifying the character of the European colonization will be best considered as they successively came into contact with the white settlers. At this point it is only necessary to state that at the same time as the Europeans were slowly extending northward from the south-western point of the continent, a conquering race of Bantu negro stock, originating from somewhere beyond the Zambezi, was spreading southward along the western side of the country.

A. *From the Discovery of the Cape to the Great Trek.*—What led to the discovery of America led also to the discovery, exploitation and colonization of South Africa. In the 15th century the great Eastern trade with Europe was carried on by the Venetian Republic—Venice was the gate from West to East, and her fleets, richly laden with goods brought down to the shores of the Mediterranean in caravans, supplied Europe with the luxuries of the Orient. It was in that century that Portugal rose to prominence as a maritime power; and being anxious to enjoy at first hand some of the commerce which had brought such prosperity to Venice, Portugal determined to seek out an ocean pathway to the Indies. It was with this intention that Bartholomew Diaz, sailing southwards, discovered the Cape of Good Hope in 1488.[1] Nine years after the discovery of the Cape by Diaz another Portuguese expedition was fitted out under Vasco da Gama. Da Gama entered Table Bay, but did not land. Thence he pushed on round the coast, landed in Mossel Bay, then sailing up the south-east coast he sighted land again on the 25th of December 1497, and named it in honour of the day, Natal. Still proceeding northwards he entered the Quilimane River and eventually reached India.

For many years subsequent to this date South Africa represented merely an inconvenient promontory to be rounded on the voyage to the Indies. Ships stopped at different ports, or rather at such few natural harbours as the inhospitable coast offered, from time to time, but no attempt was made by the Portuguese to colonize the southern end of the continent. On the west coast their southernmost settlement for a long period was Benguella, and the history of Angola (*q.v.*) had not until the last quarter of the 19th century any close connexion with that of South Africa. On the east coast the Portuguese were masters of Sofala by 1506, and a trading-post was first established in Delagoa Bay in 1545. Here alone Portugal obtained an important foothold in South Africa. But between Benguella on the west and Lourenço Marques on the east the Portuguese made no attempt to form permanent settlements or trading stations along the coast. It was too barren a shore to prove attractive when the riches of East Africa and India were available.

The first Europeans to follow in the wake of the Portuguese voyagers were the English. In 1601 the English East India Company fitted out a fleet of five vessels, which sailed from Torbay. After four months at sea they dropped their anchors in Table Bay, where they remained for seven weeks before proceeding eastwards. From that time forward Table Bay was used as an occasional port of call for British ships, and in 1620 two English captains formally took possession of the Cape in the name of James I. This patriotic act was not, however, sufficiently appreciated by either King James I. or the English East India Company to evoke any official confirmation on their part. Meanwhile the Dutch East India Company had been formed in Holland, and the Dutch had entered keenly into the competition for the glittering prizes of Eastern commerce. In 1648 one of their ships was stranded in Table Bay, and the shipwrecked crew were left to forage for themselves on shore for several months. They were so pleased with the resources of the country that on their return to Holland they represented to the directors of the company the great advantages that would accrue to the Dutch Eastern trade from a properly provided and fortified station of call at the Cape. The result was that in 1652 a fort and vegetable gardens were laid out at Table Bay by a Dutch expedition sent for the purpose under a surgeon named Jan van Riebeek.

English East India Company.

[1] The date usually assigned (1486), on the authority of De Barros, has been shown to be incorrect (see DIAZ).

In 1657 a few soldiers and sailors, discharged by the Dutch East India Company, had farms allotted them, and these men constituted the first so-called "free burghers." By this step the station became a plantation or settlement. More settlers were landed from time to time, including a number of orphan girls from Amsterdam, and during 1688–1689 the colony was greatly strengthened by the arrival of some three hundred Huguenots (men, women and children), who were located at Stellenbosch, Drakenstein, Frenchhoek and Paarl. In process of time the French settlers were absorbed in the Dutch population, but they have had an enduring influence on the character of the people. The little settlement gradually spread eastwards, and in 1754 the country as far as Algoa Bay was included in the colony. At this time the white colonists numbered eight to ten thousand. They possessed numerous slaves, grew wheat in sufficient quantity to make it an article of export, and were famed for the good quality of their wines. But their chief wealth was in cattle. Such prosperity as they enjoyed was in despite of the system of government prevailing. All through the latter half of the 17th and the whole of the 18th century troubles arose from time to time between the colonists and the government. The administration of the Dutch East India Company was of an extremely despotic character. The most complete account of the company's tenure and government of the Cape was written in 1857 by E. B. Watermeyer, a Cape colonist of Dutch descent residing in Cape Town. He points out that it was after failing to find a route by the north-east to China and Japan that the Dutch turned their eyes to the Cape route. The Cape of Good Hope subsequently "became not a colony of the Republic of the United Provinces, but a dependency of the 'Netherlands Chartered General East India Company' for mercantile purposes; and to this fact principally can be traced the slow progress, in all but extension of territory, of a country which was settled by Europeans within thirty years of the time when the Pilgrim Fathers, the founders of a mighty empire, landed at Plymouth to plant democratic institutions and European civilization in the West."

Dutch East India Company.

On the settlement under van Riebeek, and the position in it which the so-called "free burghers" enjoyed, this candid Dutch writer throws an interesting light.

"The people," he says, "who came here with Riebeek himself were not colonists intending permanently to settle at the Cape. . . . The proposition that any freemen or burghers not in the pay of the company should be encouraged to cultivate the ground was first made about three years after Riebeek's arrival. Accordingly, some discharged sailors and soldiers, who received on certain conditions plots of ground extending from the Fresh River to the Liesbeek, were the first free burghers of the colony. . . . Here it is sufficient to say that, generally, the term 'free burgher' was a complete misnomer. The first burghers were, in truth, a mere change from paid to unpaid servants of the company. They thought, in obtaining their discharge, that they had much improved their condition, but they soon discovered the reverse to be the fact. And henceforward, to the end of the last [18th] century we find the constantly repeated and well-founded complaint, that the company and its officers possessed every advantage, while the freemen were not allowed even the fruit of their own toil. . . . The natural effect of this narrow and tyrannous rule was discontent, amounting often to disaffection. After a time every endeavour was made to escape beyond the immediate control of the authorities. Thus the 'trekking' system, with its attendant evils, the bane of South Africa, was born. By their illiberal spirit, which sought but temporary commercial advantage in connexion with the Eastern trade, the Dutch authorities themselves, although generally humanely disposed towards the natives, created the system which caused their oppression and extermination."

When it is borne in mind that the Dutch at the Cape were for one hundred and forty-three years under the rule of the Dutch East India Company, the importance of a correct appreciation of the nature of that rule to any student of South African history is obvious. No modern writer approaches Watermeyer either in the completeness of his facts or the severity of his indictment. Referring to the policy of the company, Watermeyer says:—

The Dutch colonial system as exemplified at the Cape of Good Hope, or rather the system of the Dutch East India Company (for the nation should not wholly suffer under the condemnation justly incurred by a trading association that sought only pecuniary profit), was almost without one redeeming feature, and was a dishonour to the Netherlands' national name. In all things political it was purely despotic; in all things commercial, it was purely monopolist. The Dutch East India Company cared nought for the progress of the colony—provided only that they had a refreshment station for their richly laden fleets, and that the English, French, Danes and Portuguese had not. Whatever tended to infringe in the slightest degree on their darling monopoly was visited with the severest penalties, whether the culprit chanced to be high in rank or low. An instance of this, ludicrous while grossly tyrannical, is preserved in the records. Commander van Quaelbergen, the third of the Dutch governors of the colony, was dismissed from the government in 1667, and expelled the service of the company, because he had interchanged civilities with a French governor bound eastwards, the United Provinces being then at peace with France.[1]

Of this nature was the foreign policy of the Dutch company at the Cape of Good Hope; modified, indeed, in some degree from time to time, but governed by principles of jealous, stringent monopoly until the surrender of the colony by Commissioner Sluysken in 1795. The internal government of the colonists for the entire duration of the East India Company's rule was always tyrannical, often oppressive in the extreme. With proclamations, placaats and statutes abundantly filling huge tomes, the caprice of the governor was in truth the law. A mockery of popular institutions, under the name of a burgher council, indeed existed; but this was a mere delusion, and must not be confounded with the system of local government by means of district burgher councils which that most able man, Commissioner de Mist, sought to establish during the brief government of the Batavian Republic from 1803 to 1806, when the Dutch nation, convinced and ashamed of the false policy by which they had permitted a mere money-making association to disgrace the Batavian name, and to entail degradation on what might have been a free and prosperous colony, sought to redeem their error by making this country a national colonial possession, instead of a slavish property, to be neglected, oppressed or ruined, as the caprice or avarice of its merchant owners might dictate.

The Trek Boers.

From time to time servants in the direct employment of the company were endowed with the right of "freeburghers," but the company retained the power to compel them to return into its service whenever they deemed it necessary. This right to enforce into servitude those who might incur the displeasure of the governor or other high officers was not only exercised with reference to the individuals themselves who had received this conditional freedom; it was, adds Watermeyer, claimed by the government to be applicable likewise to the children of all such. The effect of this tyranny was inevitable: it drove men to desperation. They fled from oppression; and thus trekking began, not in 1835, as is generally stated, but before 1700. From 1720 to 1780 trekking had gone steadily forwards. In 1780 van Plettenberg, the governor, proclaimed the Sneeuwbergen the northern boundary of the colony, expressing "the anxious hope that no more extension should take place, and with heavy penalties forbidding the rambling peasants to wander beyond." In 1789 so strong had feeling amongst the burghers become that delegates were sent from the Cape to interview the authorities at Amsterdam. After this deputation some nominal reforms were granted; but in 1795 a number of burghers settled in the Swellendam and Graaf Reinet districts drove out the officials of the company and established independent governments. The rebellion was accompanied by an assertion of rights on the part of the burghers or freemen, which contained the following clause, the spirit of which animated many of the Trek Boers:—

That every Bushman or Hottentot, male or female, whether made prisoner by commanders or caught by individuals, as well in time past as in future, shall for life be the lawful property of such burghers as may possess them, and serve in bondage from generation to generation. And if such Hottentots should escape, the owner shall be entitled to follow them up and to punish them, according to their merits in his discretion. And as to the ordinary Hottentot, already in service, brought up at the places of Christians, the children of these shall be compelled to serve until their twenty-fifth year, and may not go into the service of any other save with their master's consent; that no Hottentot, in future deserting his service shall be entitled to refuge or protection in any part of the colony, but that the authorities throughout the country shall immediately, whatever be the alleged cause of desertion, send back the fugitive to his master.

After one hundred and forty-three years the rule of the Dutch East India Company came to an end at the Cape. What its principles were we already have seen. Watermeyer recapitulates its effects as follows:—

The effects of this pseudo-colonization were that the Dutch, as a commercial nation, destroyed commerce. The most industrious race of Europe, they repressed industry. One of the freest states in the world, they encouraged a despotic misrule in which falsely-called free citizens were enslaved. These men, in their turn, became tyrants. Utter anarchy was the result. Some national feeling may have lingered, but, substantially, every man in the country, of every hue, was benefited when the incubus of the tyranny of the Dutch East India Company was removed.

To this one further note must be added. The Trek Boers of the 19th century were the lineal descendants of the Trek Boers of the 18th. What they had learnt of government from the Dutch East India Company they carried into the wilderness with them. The end of the 19th century saw a revival of this same tyrannical monopolist policy in the Transvaal. If Watermeyer's formula, "In all things political, purely despotic; in all things commercial, purely monopolist," was true of the government of the Dutch East India Company in the 18th century, it was equally true of Kruger's government in the latter part of the 19th.

The British at the Cape.

The rule of the Dutch East India Company was extinguished (September 1795) by the occupation of the colony by the British, who acted on behalf of the prince of Orange, Holland having fallen under the control of the revolutionary government of France. Following the peace of Amiens the colony was handed over (February 1803) by Great Britain to a commissioner of the Batavian Republic. During the eight years the British held the Cape notable reforms in the government were effected, but the country remained essentially Dutch, and few British settlers were attracted to it. Its cost to the British exchequer during this period was £16,000,000. The Batavian Republic entertained very liberal views as to the administration of the country, but they had little opportunity for giving them effect. In less than three years (January 1806) the Cape was reconquered by the British, who were at war both with France and Holland. The occupation was at first of a provisional character, but by the third additional article to the convention with the Netherlands of the 13th of August 1814 the country was definitely ceded to Great Britain. In consideration of retaining the Cape and the Dutch settlements now constituting British Guiana, Great Britain paid £6,000,000. The British title to Cape Colony is thus based upon conquest, treaty and purchase. The wishes of the inhabitants were not consulted, and among them resentment was felt at the way in which their future was thus disposed of. The Europeans at the Cape at that time numbered about 27,000.

Early Relations with the Native Races.

Before tracing the history of South Africa during the 19th century, the early relations of the white settlers with the natives may be briefly reviewed. The natives first encountered at the Cape were the Hottentots (*q.v.*). They at that time occupied the Cape peninsula and surrounding country, and in the early days of the settlement caused the colonists a considerable amount of trouble. An extract from the diary of van Riebeek in 1659 will best illustrate the nature of the relations existing between colonists and natives at that time:—

3rd June.—Wet weather as before, to the prevention of our operations. Our people who are out against the plundering Hottentots, can effect nothing, neither can they effect anything against us; thus during the whole week they have been vainly trying to get at our cattle, and we have been trying vainly to get at their persons: but we will hope that we may once fall in with them in fine weather, and that the Lord God will be with us.

[1] It was not until the time of Ryk Tulbagh (governor of the colony, 1751–1771) that the Chamber of Seventeen permitted foreign ships to provision at Table Bay. Tulbagh was the most popular of the governors under the East India Company. During his governorship no new taxes were levied on the burghers. He was succeeded by van Plettenberg.

Next to the Hottentots the white settlers encountered the Bushmen (*q.v.*). When first known to the early colonists they were inveterate stock thieves, and were treated as wild animals, to be shot whenever an opportunity occurred.[1] Such opposition as Hottentots and Bushmen were able to offer to European colonization was not difficult to overcome (see Cape Colony: *History*). The expansion of the colony was little retarded by native opposition until the Dutch encountered the Bantu negro tribes. As already stated, the Bantus, like the Europeans, were invaders of South Africa, and the meeting of these rival invaders was the cause of many bloody conflicts. At first the Cape government endeavoured to come to an amicable arrangement with the new power threatening its eastern border, and in 1780 it was agreed that the Great Fish River should be the permanent boundary between the colonial and Bantu territories. The Bantus or Kaffirs (*q.v.*), as they were universally called, then held all the coast-lands between Delagoa Bay and the Great Fish River, and for many years they were strong enough to bar the further progress eastward of the white races. But the agreement of 1780 was impossible of fulfilment. The peace was broken in 1789 by an invasion of the colonial territory by the Kaffirs, and this conflict proved to be but the first of a series of Kaffir wars which lasted for a century. In 1811 it was deemed necessary to expel the Kaffirs from the Zuurveld, and the British headquarters in that campaign became the site of Graham's Town. In 1817–1819 the Kaffirs returned and laid waste a large area. They were driven back and the country up to the Keiskama River annexed to the colony; but the disaster which nearly overwhelmed the eastern province convinced Lord Charles Somerset, then governor of the colony, of the necessity for a line of frontier forts and a more numerous settlement of colonists. Representations on the matter in England, coupled with assurances from Somerset as to the fertility of the district, induced the British government to vote £50,000 for the purpose of sending out a number of emigrants, Applications were called for, and no fewer than 90,000 were received. Of these, only 4000 were selected and shipped to South Africa. They were landed in 1820, in Algoa Bay, where they founded Port Elizabeth and the Albany settlement. Among these settlers were a number of married men with families. They were recruited from England, Ireland and Scotland, and came from all grades of society. Among them were cadets of old families, retired officers, professional men, farmers, tradesmen, mechanics and labourers. They encountered many difficulties and some suffering in their early days, but on the whole they throve and prospered. Their descendants, the Atherstones, Bowkers, Barbers, Woods, Whites, Turveys, and a number of other well-known frontier families, are to-day the backbone of the eastern district of the Cape, and furnish the largest portion of the progressive element in that province. Among them was a gifted Scotsman named Thomas Pringle (1789–1834). His poems, including "Afar in the desert I love to ride," depict the scenes of those early days in glowing lines. The vast spaces of the veld, the silence of the solitudes, the marvellous, varied and abundant animal life, the savage, half-weird character of the natives and the wild adventure of the early colonists have been caught with a true spirit of genius. Since his day no one, unless it be Olive Schreiner in *The Story of an African Farm*, has so vividly painted the life and the atmosphere of that vast continent lying to the south of the Zambezi.

British Settlers of 1820.

Various Protestant missions had sent agents among the natives during the closing years of the 18th century, and after the definite acquisition of the Cape by Great Britain the number of missionaries in the country greatly increased. Many became pioneers, settling in regions beyond the limits of British jurisdiction. Others remained within Cape Colony, while several were stationed among the Kaffirs along the colonial border. The missionaries from the first often found themselves at variance with the Dutch and also the British settlers, whose methods of dealing with the natives often deserved condemnation. At this period Dr John Philip (*q.v.*), of the London Missionary Society, was the most prominent of the missionaries in the colony, and his influence was powerful with the home government. The publication in 1828 of his book *Researches in South Africa* had an important effect on the future of the country. The British government adopted his negrophil attitude and made its agents at the Cape conform to it. The equality of all free Hottentots and other free persons of colour with the white colonists was decreed in that year (1820). Philip's action lacked discrimination, and his faith in the natives was excessive. His charges greatly embittered the Boers, who were further aggrieved by the emancipation of the slaves. The Slave Emancipation Act, freeing all slaves throughout the British Empire, came into force in December 1834.[2] The slaves in Cape Colony, who consisted of negroes from Mozambique, natives of Madagascar, and of Hottentots and Malays were estimated at the time at 36,000. The Cape governments—both Dutch and British—had been consistently averse from the importation of slaves in large numbers, and the great majority of the slaves were therefore Hottentots. The sum voted by the British government to slave-owners in Cape Colony, out of a total compensation paid of £20,000,000, was £1,250,000 (the official estimate of their value being £3,000,000). This money was only made payable in London, and the farmers were compelled to sell their claims for compensation to agents, who frequently paid a merely nominal price for them. In many instances farmers were unable to obtain native labour for a considerable time after the emancipation, and in several cases ruin was the result. A very bitter feeling was thus created among the Dutch colonists.

Emancipation of Slaves.

The championship of the natives by the missionaries led to attacks, in part justified, upon the policy of the missions not only by the Dutch, but by the British colonists. The zeal of the missionaries frequently outran their discretion. This was especially the case in early days. They not only endeavoured to protect and guide the natives beyond the colonial border, but among the Hottentots within the colony they instilled notions of antipathy to the white farmers, and withdrew large numbers of them from agricultural pursuits. Their general attitude may be explained as a reaction against the abuses which they saw going on around them, and to a misconception of the character of the Hottentot and Bantu races. A longer experience of all the African negroid races has led to a considerable modification in the views originally held in regard to them. The black man is not simply a morally and intellectually undeveloped European, and education, except in rare instances, does not put him on an equality with the European. But, admitting all that may be justly urged against the extreme attitude of some of the missionaries, no unprejudiced man will deny that their work on the whole has been a good one. The fair fame of Great Britain has more than once been upheld in South Africa at the instigation and by the conduct of these intrepid pioneers. Robert Moffat and David Livingstone among the Bechuanas, E. Cassalis among the Basutos, François Coillard among the Barotse, James Stewart in Cape Colony, to name but a few of the great missionaries, have all had an excellent influence upon the natives. They have (besides their purely spiritual work) opposed the sale of alcohol, denounced inhumanity from the farmers, encouraged the natives to labour and taught them mechanical arts. Technical education, begun about 1840, now occupies a position little, if at all, inferior to that of doctrinal teaching, and the effect is an excellent one. Strong testimony to the beneficial result of their labours was borne by a thoroughly impartial commission, presided over by Sir Godfrey Lagden, which in 1903–1905 investigated the status and condition of the natives of South Africa.

Work of the Missionaries.

To return to the period of Dr Philip's activity.[3] Largely upon

[1] It appears that the first persons to treat the Bushmen other than as animals to be destroyed were two missionaries, Messrs J. J. Kicherer and Edwards, who in the early years of the 19th century devoted themselves to ameliorating the lot of these aborigines.

[2] The slaves, after passing four years in a species of apprenticeship, were finally freed on the 1st of December 1838.

[3] At this time (*c.* 1815–1840) numbers of persons brought discredit on the missionary cause by their illiteracy, narrow-minded prejudices

his advice it was decided to create a band of native states on the northern and eastern frontiers of the colony. These treaty states, as they were called, were intended to serve a double purpose; they would be a barrier protecting the colony from the inroads of hostile tribes, and they would enable native civilized nations to grow up (under the tutelage of the missionaries) strong enough to protect themselves from the encroachments of the whites. In fact, neither of these results followed. With one exception, that of Moshesh, the chief of the Basutos, none of the chiefs with whom treaties were made were men powerful enough to found kingdoms, nor had they, in most cases, any better right than their neighbours to the territory recognized as theirs by the British government. Moreover, to treat these men as independent or semi-independent princes was a complete mistake; the failure of the treaty state system is now seen to have been inevitable. The first treaty of this kind was concluded on the 11th of December 1834 with a Griqua chief named Andries Waterboer. This chieftain lived north of the Orange river in the district now known as Griqualand West, and ruled over some 4000 people, a bastard race sprung from the intercourse between Boers and native women. In 1843 two more of these treaty states were established, one under Adam Kok (the third of that name) and the other under Moshesh. Adam Kok had under him a small number of Griquas, who dwelt in the country east of that occupied by Waterboer (see GRIQUALAND). And east of this country, again, was a tract of territory occupied by Basutos under Moshesh. In the same way Pondoland was established as a treaty state in 1844. The distinction between these states must be remembered to understand aright subsequent developments. Moshesh ruled over a region largely mountainous and over a people numerous and virile; Pondoland was somewhat remote and was densely inhabited by warlike Kaffirs; the two Griqua states were, however, missionary creations; they were thinly inhabited and occupied open plains easy of access—hence their ultimate collapse.

Treaty States.

The year which witnessed the emancipation of the slaves and the creation of the first treaty state also saw the beginning of another disastrous Kaffir war. Fighting began in December 1834, and lasted nearly a year. The Kaffirs wrought great havoc, and Sir Benjamin D'Urban (*q.v.*), the governor, in order to secure peace, extended the boundary of the colony to the Kei river. The Kaffirs had suffered much injustice, especially from the commando-reprisal system, but they had also committed many injustices, and for the disturbed state of the border the vacillating policy of the Cape government was largely to blame. Sir Benjamin's policy—which had the cordial approval both of the Dutch and the British colonists—was one of close settlement by whites in certain districts and military control of the Kaffirs in other regions, and it would have done much to ensure peace. Lord Glenelg, secretary for the colonies in Lord Melbourne's second administration, held that the Kaffirs were in the right in the quarrel, and he compelled D'Urban to abandon the conquered territory, a mistaken decision adopted largely on the advice of Dr Philip and his supporters. Thus at this time (1836) a critical state had arisen in South Africa. The colonists had lost their slaves, the eastern frontier was in a state of insecurity, native interests appeared to be preferred to those of the whites. The British immigrants of 1820 were still struggling against heavy odds; the Dutch colonists were in a state of great indignation. In these circumstances what is known as the Great Trek occurred. It lasted from 1836 to 1840. During that period no fewer than 7000 Boers (including women and children), impatient of British rule, emigrated from Cape Colony into the great plains beyond the Orange river, and across them again into Natal and into the fastnesses of the Zoutspanberg, in the northern part of the Transvaal.

The Great Trek.

In view of the vast consequences ensuing from this exodus of Dutch families from the Cape a somewhat detailed consideration of its causes is necessary. Material for forming a judgment will be found chiefly in the correspondence of Sir Benjamin D'Urban with the Colonial Office, in the statements made by the voortrekkers, and in a series of lectures delivered in Pietermaritzburg in 1852–1855 by the Hon. Henry Cloete, whose statements as to the causes of the trek were founded on intimate knowledge and are impartially set forth. Piet Retief, the ablest of the leaders of the exodus, on the eve of leaving the colony published a declaration at Graham's Town, dated January 22nd 1837, in which he declared the chief reasons animating the emigrants to be:—

1. We despair of saving the colony from those evils which threaten it by the turbulent and dishonest conduct of vagrants, who are allowed to infest the country in every part; nor do we see any prospect of peace or happiness for our children in a country thus distracted by internal commotions.

2. We complain of the severe losses which we have been forced to sustain by the emancipation of our slaves, and the vexatious laws which have been enacted respecting them.

3. We complain of the continual system of plunder which we have ever endured from the Kafirs and other colored classes, and particularly by the last invasion of the colony, which has desolated the frontier districts and ruined most of the inhabitants.

4. We complain of the unjustifiable odium which has been cast upon us by interested and dishonest persons, under the cloak of religion, whose testimony is believed in England to the exclusion of all evidence in our favour; and we can foresee, as the result of this prejudice, nothing but the total ruin of the country.[1]

These four points correspond to the "three great grievances" under which the farmers suffered, enumerated by Cloete as (1) The Hottentot Question (*i.e.* the first and fourth points of Retief's manifesto combined); (2) The Slave Question; (3) The Kaffir Question. Enough has already been said as to the relations between the missionaries, the Boer farmers and the Hottentots; this grievance, however, "proved quite secondary to the intensity of feeling with which the colonists saw the steps taken by the government to deprive them of that labour (slave labour) over which they claimed an unquestionable right of property."[2] Then came the Kaffir War of 1834–1835, the reversal by the home government of the statesmanlike settlement of Sir Benjamin D'Urban, and the refusal of any compensation to the sufferers from the war, whose losses amounted to some £500,000. These, then, were the direct causes of the voluntary expatriation of the majority of the first trekkers, who included some of the best families in the colony, but they fail to explain the profound hostility to Great Britain which thereafter animated many, but not all, of the emigrants, nor do they account for the easy abandonment of their homes by numbers of the trekkers. The underlying fact which made the trek possible is that the Dutch-descended colonists in the eastern and north-eastern parts of the colony were not cultivators of the soil, but of purely pastoral and nomad habits, ever ready to seek new pastures for their flocks and herds, and possessing no special affection for any particular locality. In the next place these people, thinly scattered over a wide extent of territory, had lived for long under little restraint from the laws, and when in 1815, by the institution of "Commissions of Circuit," justice was brought nearer to their homes, various offences were brought to light, the remedying of which caused much resentment. An effort to bring a man named Frederick Bezuidenhout to justice led to armed resistance and finally to the hanging of five men at Slachter's Nek in circumstances that made an indelible impression throughout the frontier (see CAPE COLONY: *History*). It intensified in the minds of many Boers the feeling of hostility towards the British already existing; some of the trekkers in 1836–1840 had taken part in and others had passively aided the rebellion of 1815—"the most insane attempt ever made by a set of men to wage war against their sovereign" (Cloete, *op. cit.* p. 28). What, however, was probably the most powerful motive of the Great Trek was the equality established by the British between the black and white races. In the eyes of the Boers the possibility of equality between the whites and the natives was not

and in some cases lax sexual morality. These persons "assumed to themselves the important office of teachers in the missionary schools within the colony." See H. Cloete's *The Great Boer Trek*, lecture II.

[1] See F. R. Cana, *South Africa from the Great Trek to the Union* (London, 1909), pp. 295–297 for the full text of Retief's manifesto.

admitted. This sentiment, which found formal recognition later on in the constitution of the South African Republic, was held in fullest force by the voortrekkers. Summing up, it may be said that the exasperation caused by just grievances unremedied was no stronger a motive with the trekkers than the desire to be free from the restraints imposed on British subjects and the wish to be able to deal with the natives after their own fashion.

The departure of so large a number of persons caused serious misgiving both to the Cape and the home governments. The trekkers had been told by the lieutenant-governor of the eastern province (Sir Andries Stockenstrom) that he was not aware of any law which prevented any British subject from settling in another country, and in the words of Piet Retief's declaration they quitted the colony "under the full assurance that the English government has nothing more to require of us, and will allow us to govern ourselves without its interference in future." The British government thought otherwise; they held that the trekkers could not divest themselves of their allegiance to the Crown. Moreover, though the farmers might leave British territory they were still held to be liable to the jurisdiction of British courts. An act passed in 1836 (the Cape of Good Hope Punishment Act) empowered the colonial courts to deal with offences committed by British subjects in any part of South Africa up to the 25th degree of south latitude. Intended by its authors to protect the native tribes from aggression on the part of white men and to check the exploration by Europeans of the lands of the Kaffirs, Bechuanas, &c., the act led in fact to the assertion of British authority in regions beyond the Cape frontier.

B. *From the Foundation of the Republics to Majuba.*—While the home government was seeking to prevent the expansion of the white races the first steps had been taken by a body of Englishmen to found a new colony at Natal. Since 1824 a few traders had been settled at Port Natal, and in 1834 formal petition was made that their settlement should be recognized as a British colony. The request was refused, and not long afterwards (1837) some of the Dutch emigrant farmers under Retief entered the country by way of the Drakensberg. Retief, like his English predecessors at Port Natal (known also since 1835 as Durban), sought a formal grant of territory from the chief of the Zulu nation, the Zulus being the acknowledged overlords of the tribes living in Natal. Retief and his party were, however, treacherously murdered by Dingaan, the Zulu king (February 1838). Other trekkers followed in the wake of Retief, and attacking Dingaan avenged the massacre.

Foundation of the Boer Republics and Natal.

The Boers then established a republican government at Maritzburg. Though most anxious to avoid any extension of responsibility in South Africa, Great Britain recognized the potential danger arising from the creation of an independent state on the coast. The Boers at first rejected offers of accommodation. Troops were then sent to the country, and finally a settlement was made by Henry Cloete, the British commissioner, with the Boer leaders, and Natal constituted a British colony in 1843. Many Boers, dissatisfied with this arrangement, withdrew beyond the Drakensberg. Natal shortly afterwards received a considerable number of emigrants from England, and the white inhabitants have since been predominantly British. At first Natal was dependent on Cape Colony. In 1856 it was constituted a separate colony, but it did not possess self-government until 1893. A notable departure from the labour policy of the other states was made by Natal in 1860, when Indian coolies were introduced. At the time the matter attracted little attention, but the Asiatic inhabitants speedily increased, and forty years later they outnumbered the whites (see NATAL).

It had taken the British government nearly ten years to decide on the annexation of Natal; its policy towards the Boers settled north of the Orange was marked by the same hesitation (see ORANGE FREE STATE). By 1847, when Sir Harry Smith became high commissioner, the failure of the treaty state policy was evident. Sir Harry, deeming no other course open to him, proclaimed (February 1848) the country between the Orange and Vaal rivers British territory, under the name of the Orange River Sovereignty. Sir Harry had, in the previous December, extended the northern frontier of Cape Colony to the Orange, and had reoccupied the territory on the Kaffir border which D'Urban had been forced to abandon.[1] The extension of British rule north of the Orange was opposed by Andries Pretorius, who, being defeated at Boomplaats, withdrew north of the Vaal, where, though not interfered with by the British, the Boers split up into several rival parties. In the Sovereignty difficulties arose in defining the reserves of the native chiefs, and with the Basutos there were armed conflicts. The home government (the first Russell administration), which had reluctantly consented to confirm Sir Harry Smith's annexation of the Orange River territory, on learning of these difficulties, and also that many of the burghers remained dissatisfied, changed their policy, and in 1851 the governor was informed that the ultimate abandonment of the Sovereignty was a settled point.[2] In fulfilment of their settled policy to keep the British South African dominions within the smallest possible limits, the cabinet decided to recognize the independence of the Boers living beyond the Vaal. This recognition, the necessary preliminary to the abandonment of the Orange River Sovereignty, was made in the Sand River Convention on the 17th of January 1852. The Transvaal thus became an independent state, or rather it formed a number of mutually jealous communities, and it was not until 1864 that they were all united. Despite their distracted condition the Transvaal Boers had no sooner obtained their independence than they began to make claims to authority in Bechuanaland. But the championship of the Bechuanas by Moffat, Livingstone and other missionaries, and their determination that the road to the interior should not be closed by the Boers, had its effect, and the Boers did not succeed in making themselves masters of the country (see TRANSVAAL: *History*, and BECHUANALAND). The British government meantime pursued its policy of abandonment, and in February 1854, by the Bloemfontein Convention, forced independence upon the people of the Sovereignty, which now became the Orange Free State. A clause was inserted in the Bloemfontein Convention stating that Great Britain had no alliance with any native chiefs or tribes to the north of the Orange, with the exception of the Griqua chief Adam Kok. Numerous protests were made by many of the inhabitants of the Orange River Sovereignty against the abandonment of it by the British government, but the duke of Newcastle, who was then colonial secretary in Lord Aberdeen's administration, replied that the decision was inevitable (see ORANGE FREE STATE).

Orange River Sovereignty.

Independence of the Transvaal Recognized.

Orange Free State.

The abandonment of the Orange River Sovereignty marked the close of the eventful period in South African history which began eighteen years before with the Great Trek. At the beginning of that time there was but one civilized government in South Africa—Cape Colony; at its close there were five separate states or provinces, three, the Cape, Natal and British Kaffraria, owning allegiance to Great Britain, and two forming Boer republics—the Transvaal and Orange Free State. While vast additional territories had been occupied by British or Boers the unity of administration, which had marked the previous stages in the expansion of the white races in South Africa, had been lost. Whether or not a wiser policy on the part of Great Britain would have secured the continued allegiance of all the Boers it is impossible to say; the fact that numbers of Boers remained in Natal under British rule, and that the majority of the Boers who settled between the Orange and the Vaal desired to remain British subjects, points to that conclusion. With justice the Boers complained of the course actually adopted by the British authorities. They might at the outset either have let the trek Boers go, and given them their blessing and liberty, or they might have controlled the trek and

Results of a Policy of Vacillation.

[1] Part of the territory thus reannexed was added to Cape Colony while the region between the Keiskamma and Kei was created a separate territory under the name of British Kaffraria.

[2] Despatch of Earl Grey, dated October 21st, 1851, printed in *Correspondence Relative to the State of the Kaffir Tribes* (C. Feb. 1853).

made effective their contention that the trekkers were still British subjects. As has been demonstrated the action taken was one of vacillation between these two courses. and was complicated by a native policy which, though well intentioned and intelligible, needlessly irritated the white colonists (British and Dutch) and did not prevent bloodshed. In the words of Mr Paul Botha, a Boer writer, England first blew hot and then blew cold. But in 1854 a definite standpoint appeared to have been reached—Great Britain would confine her energies to the Cape and Natal, leaving the republics to work out their own destinies undisturbed. It was at this juncture that Sir George Grey was sent to the Cape as governor. A gifted and far-seeing man, he had no sooner arrived than he addressed himself with energy and diligence to the great problems awaiting him. His first care was to ameliorate the condition of Cape Colony. He resolved that in dealing with the natives on the eastern frontier an attempt should be made to civilize them and thus do away with the necessity of periodical warfare. Grey's efforts to promote good government in Kaffraria received unexpected help in consequence of the extraordinary delusion among the Ama-Xosa in 1856, which resulted in the death of many thousands of natives (see CAPE COLONY: *History*). Land left derelict was occupied by colonial farmers, and over 2000 German immigrants were introduced by Sir George and settled along the frontier (1858–1859). By this time the colonists of British descent predominated in the eastern provinces—a circumstance which had important bearings on the future of the colony.

Sir George Grey.

Sir George Grey found it impossible to maintain a policy of total abstention from the affairs of the republics. The party in the Free State which had objected to independence being forced upon it was still strong and made overtures for union with the Cape; attempts were also made to unite the Free State and the Transvaal. In the conflicts between the Free Staters and the Basutos Grey's intervention was sought. All the evidence before Sir George, and the study he made of the Boer character, convinced him that the barriers separating the various white communities were largely artificial. He sought to remedy the mistake which had been made, and in 1858 he submitted a scheme of federation between the various South African states. In a memorable despatch to Sir E. Bulwer Lytton, then colonial secretary in the second Derby administration, he wrote (November 19, 1858):—

> When the policy was adopted of dividing South Africa into many states, bound together by no ties of union, it was thought that the mother country derived no real benefit from the possession of this part of the African continent, except in holding the seaport of Simon's Bay. . . . It was further thought that the occupation by Great Britain of the country beyond the Orange River had been a bubble and a farce, in which the Cape colonists were all interested; for that it was to them a great gaming table and out of the reach of the police. . . . Although these European countries lying beyond our colonies are treated as separate nations, their inhabitants bear the same family names as the inhabitants of this colony, and maintain with them ties of the closest intimacy and relationship. . . . I think there can be no doubt that in any great public, or popular, or national question and movement the mere fact of calling these people different nations would not make them so, nor would the fact of a mere fordable stream running between them sever their sympathies or prevent them from acting in unison. . . . Experience has shown that the views which led to the dismemberment of South Africa were mistaken ones. . . . What therefore I would recommend would be that . . . measures should be taken which would permit of the several states and legislatures of this country forming among themselves a federal union.

When he penned this despatch Grey was well aware of the distraught condition of the Free State and the agitation for a change in its government. He held that the federation of that state with Cape Colony was preferable to its union or federation with the Transvaal, and it was with considerable satisfaction that he learned that on the 7th of December of the same year (1858) the Volksraad of the Free State had passed a resolution in favour of "a union or alliance with the Cape Colony" and sought to ascertain the views of the Cape legislature on the subject. In bringing the matter before the Cape parliament in March 1859 Grey stated that in his opinion it would confer a lasting benefit upon Great Britain and upon the inhabitants of South Africa if it could succeed in devising a form of federal union. Unfortunately, Grey's views did not meet with the approval of the British government.[1] Had they been supported it is highly probable that federation would have been effected. But the golden opportunity was lost. When Grey attempted to persevere with his scheme he was recalled. He left Cape Town in August 1859, but on his arrival in England he found that there had been a change of ministry. The new colonial secretary, the duke of Newcastle, reinstated him, but with instructions not again to raise the federation issue. The first project for reunion thus came to naught, but from that time forward it was recognized in South Africa that federation would afford the best solution of most of the difficulties that beset the country. The Transvaal was perhaps the greatest sufferer through Grey's failure, that country continuing for years in a distracted condition. The Free State, under the guidance of Sir John Brand, who became president in 1864, attained a considerable measure of prosperity. Its difficulties with the Basutos were at last composed, and Moshesh and his people were in 1868 definitely taken under British protection. The policy of non-interference proclaimed in 1854 had proved impracticable, and the annexation of Basutoland was an open confession of the fact. In 1871 the country was annexed to Cape Colony, but its pacification proved a task of great difficulty.

First Confederation Proposal.

Economic Development.

Up to the year 1870 the Dutch considerably outnumbered the British inhabitants; indeed, save in Natal, in the eastern province and in Cape Town, the British inhabitants were comparatively few. The industries were almost entirely pastoral, and remained chiefly in the hands of the Dutch. The continual feuds with the Kaffirs, and also the continual desire to trek into new countries, all tended to keep back farming, and the country in the years 1867 to 1870 was in a generally very depressed condition. But in 1870 the era of commercial expansion began. In that year, following smaller finds of diamonds on the banks of the Vaal and Orange rivers, the diamond mines of Du Toits Pan and Bultfontein were opened up. In 1869 gold had been found in the Lydenburg and Zoutpansberg districts in the Transvaal, and diggers had resorted there from different parts of the world; moreover, in the far interior, in the territories of Mashonaland, Thomas Baines had reported discoveries of gold. Among the purely pastoral population ostrich-farming became a new industry and added a considerable asset to the wealth of Cape Colony. The revenue derived from the export of ostrich feathers in 1899 was recorded at half a million. It was, however, the discoveries of diamonds and gold that chiefly determined the development of the country. A large population grew up, first at Kimberley, afterwards at Barberton, and finally at Johannesburg—a population modern in its ideas, energetic, educated, cosmopolitan, appreciating all the resources that modern civilization had to offer them, and with a strong partiality for the life of the town or the camp rather than that of the farm and the veld. The majority of the Boers remained very much what they had been in the 17th century. Their life of continual strife with natives, continual trekking to fresh pastures, had not been conducive to education or the enlargement of intellectual outlook. In religion they were Calvinistic, fanatic, and their old traditions of Dutch East India government, together with their relation to the natives, developed a spirit of caste and even tyranny.

The Carnarvon Confederation Scheme.

It was at this stage of affairs that responsible government was granted to Cape Colony (1872). From that time down to the annexation of the Transvaal in 1877, to quote once more the homely phrase of Paul Botha, Great Britain "blew hot" in South Africa. A great change in public sentiment towards the colonies generally began to make itself felt in Great Britain in the late sixties and early seventies of the 19th century. The constitution of the Dominion of Canada (1867–1873) was an evidence of that feeling.

[1] Sir E. Bulwer Lytton wrote (Feb. 11, 1859): "H.M. Government are not prepared to depart from the settled policy of their predecessors by advising the resumption of British sovereignty in any shape over the Orange Free State."

With the advent to power of the Disraeli ministry in 1874 the nascent Imperial spirit grew in strength. Lord Carnarvon (the 4th earl), when under-secretary for the colonies in 1858–1859, had regarded Grey's federation proposal with disfavour, but later, as secretary of state, he had introduced the bill for the federation of the Canadian provinces. He now returned to the Colonial Office filled with the idea of doing for South Africa what had been done in British North America.[1] Recent events in South Africa had appeared for a brief period to favour a union of its various colonies and states. The intimation of the impending grant of self-government to Cape Colony was regarded by both Boer republics as bringing nearer the prospect of their union with the British colonies. But just at that time differences arose between Great Britain and the republics as to the ownership of the Kimberley diamond fields which estranged the Boers (see GRIQUALAND and TRANSVAAL). In the Transvaal Pretorius was succeeded by T. F. Burgers, a man totally unfitted to govern a country distracted by factions, harassed by wars with natives, and with an almost depleted exchequer. Yet in the condition of the Transvaal Lord Carnarvon found another argument in favour of federation. Union with the neighbouring states would, he thought, cure its ills and promote the general welfare of South Africa. As a preliminary step he accepted an offer from J. A. Froude to visit South Africa unofficially, and by travelling through its different states find out what were the obstacles to confederation and the means by which such obstacles could be removed. Froude landed at Cape Town on the 21st of September 1874, and having visited Natal, the Free State and Pretoria as well as Cape Colony, sailed for England on the 10th of January 1875. In the three and a half months he had spent in the country he had reached the conclusion expressed by the duke of Newcastle nearly twenty years previously, namely, that all England needed there was Table Bay—or the Cape peninsula—as a naval and military station. The South African states, he believed, might be left in internal affairs to work out their own future. These views coincided with those of Lord Carnarvon, who looked to federation as a means of relieving the Imperial government of some of the heavy responsibilities pressing upon it in South Africa, and he asked Froude to return to the Cape to take part in a conference in South Africa on the federation scheme. The offer was accepted, and Froude reached Cape Town again in June 1875. Lord Carnarvon's despatch (May 4, 1875), indicating his views, had preceded the arrival of Froude, and had incensed J. C. Molteno, the Cape premier, by its disregard of the colony's self-governing powers. A motion was carried in the Cape parliament affirming that any movement for federation should originate in South Africa and not in England. Froude on his arrival was much chagrined at the attitude taken by the Cape parliament, and conducted an oratorical campaign throughout the country in favour of federation. His speeches were lacking in judgment and tact, and created an unfavourable impression. The conference was not held, and Froude returned to England in the autumn.[2]

Lord Carnarvon was far from abandoning his plan. The Transvaal was now in a condition bordering on anarchy, and numbers of its inhabitants were supposed to be looking to Great Britain for help. Another party in the Transvaal was seeking alliances with Germany and Portugal, and this danger of foreign interference was a further cause for action. In August 1876 the colonial secretary assembled a conference on South African affairs in London, nominating Froude as representative of Griqualand West. President Brand represented the Free State. Another member of the conference was Sir Theophilus Shepstone, (*q.v.*) Neither Cape Colony nor the Transvaal was represented, and the conference was abortive, President Brand having no permission from his state to consider federation. That subject was, in fact, not discussed by the delegates. In view of the troubles in the Transvaal, and in furtherance of Carnarvon's federation scheme, Shepstone was, on the 5th of October following, given a dormant commission to annex the republic "if it was desired by the inhabitants and in his judgment necessary." The secretary of state sought the aid of Sir Bartle Frere as his chief agent in carrying through confederation, the then governor of Cape Colony and high commissioner for South Africa, Sir Henry Barkly, sharing the views of the Cape ministry that the time was inopportune to force such a step upon South Africa. In a letter dated the 13th of October, offering Frere the post Barkly was about to vacate, Lord Carnarvon wrote:—

> . . . The war between the Transvaal republic and the natives has had this further effect, it rapidly ripened all South African policy. . . . It brings us near to the object and end for which I have now for two years been steadily labouring—the union of the South African colonies and states. I am indeed now considering the details of a bill for their confederation, which I desire to introduce next session, and I propose to press, by all means in my power, my confederation policy in South Africa.

First Annexation of the Transvaal.

The time required for the work of confederating and of consolidating the confederated states Lord Carnarvon estimated at not more than two years, and he was sanguine enough to hope that Frere would stay on at the Cape for two or three years "as the first governor-general of the South African dominion." Frere accepted the offer, but did not leave England until March 1877. Shepstone preceded him, and in January 1877 had gone to Pretoria. His conferences with the leading men in the Transvaal and a consideration of the dangers which threatened it and the grave disorders within its borders satisfied Shepstone that he had no choice except to act upon his commission, and on the 12th of April he issued a proclamation annexing the country to the British Crown. During the interval between Shepstone's arrival in the country and the annexation the Volksraad had rejected the proposals for confederation laid before them in accordance with Lord Carnarvon's permissive bill, and had made no real attempt at reform. The annexation was acquiesced in by a considerable number of the white inhabitants. Shepstone was convinced that it was the only step which could save the country from ruin. The subject is discussed at greater length under TRANSVAAL. Frere, who had reached Cape Town on the 31st of March, learnt on the 16th of April that the annexation had taken place. He was inclined to regard Shepstone's act as premature, and he realized that it stirred very deeply Dutch national feeling throughout South Africa. Though anxious to promote Carnarvon's policy, Frere found that native affairs called for immediate attention. The Basuto and Kaffir tribes were giving trouble, and the 40,000 trained Zulu warriors under Cetywayo threatened the peace both of Natal and the Transvaal. In the same month (Aug. 1877) in which the British parliament passed the act, foreshadowed by the secretary of state, "for the union under one government of such of the South African colonies and states as may agree thereto," another war with the Kaffirs broke out. This conflict lasted until May 1878, and largely absorbed the energies of Sir Bartle Frere.[3] In the meantime a scheme of unification, as opposed to federation, put forward by the Molteno ministry—a scheme which in its essence anticipated the form of government established in 1910—had met with no support from Frere or the home ministry. In January 1878 Lord Carnarvon resigned, and the driving force of the federation scheme thus disappeared. It was not, however, finally dropped until 1880. In July of that year proposals for a confederation conference were submitted to the Cape parliament. At that time Paul Kruger and Piet Joubert, delegates from the Transvaal Boers, were in Cape Town, and they used their influence to prevent the acceptance of the proposals, which were shelved by the ministry accepting "the

[1] At Sir Henry Barkly's request Lord Carnarvon's predecessor, Lord Kimberley, had in November 1871 given him (Sir Henry) authority to summon a meeting of representatives of the states and colonies to consider the "conditions of union," but the annexation of the diamond fields had occurred meantime and Sir Henry thought the occasion inopportune for such a conference.

[2] For Froude's views and actions, see especially the blue book C. 1399 (1876), containing his report to Lord Carnarvon.

[3] Serious troubles with the Basutos which began in 1879 reacted on the situation in the Transvaal and Natal. These troubles were finally ended in 1884, when the country was given up by the Cape and became a crown colony (see BASUTOLAND).

previous question" (June 29). Thus ended an attempt which lacked the element essential to success—spontaneity.

Confederation had, for the time being, ceased to be a living issue some time before its formal shelving by the Cape parliament. The Kaffir War of 1878 was followed by war with the Zulus. Frere, believing that the Zulu power was a standing menace to the peace of South Africa, and that delay in dealing with Cetywayo would only increase the danger, sent an ultimatum to the chief in November 1878. The invasion of Zululand began in January 1879, and was speedily followed by the disaster at Isandhlwana and by the defence of Rorke's Drift and of Eshowe. But at the battle of Ulundi in July the Zulu power was crushed, and a little later Cetywayo was taken prisoner (see ZULULAND: *History*). The removal of the Zulu danger did not, however, restore harmony between the British and the Boers in the Transvaal. The malcontent Boers became a powerful element in the country. They were largely influenced by an important section of the Dutch community in western Cape Colony, which carried on a campaign against annexation, seeing in it a blow to the ideal they had begun to entertain of a united South Africa of a Dutch republican type. Sir Garnet Wolseley, at this period (June 1879–May 1880) high commissioner of South-East Africa, gave the Transvaal a legislative council, but the members were all nominated. This could not be regarded as a redemption of the promise of a liberal constitution, and it had an injurious, though limited, effect on the Boer community.[1] After the receipt in December 1879 of the reports of Mr Gladstone's speeches during his Midlothian campaign—in which he denounced annexation as obtained by means dishonourable to Great Britain—the Boers expected nothing less than the retrocession of the country.

There was one strong reason against retrocession, concerning which the Boers—if they gave it thought—would naturally be silent. To the British mind in general it was apparently non-existent. It had, however, been seen and its strength recognized by Sir Garnet Wolseley during his brief governorship of the Transvaal. Wolseley, in a despatch dated the 13th of November 1879 said:—

> The Transvaal is rich in minerals; gold has already been found in quantities, and there can be little doubt that larger and still more valuable goldfields will sooner or later be discovered. Any such discovery would soon bring a large British population here. The time must eventually arrive when the Boers will be in a small minority, as the country is very sparsely peopled; and would it not therefore be a very near-sighted policy to recede now from the position we have taken up here, simply because for some years to come the retention of 2000 or 3000 troops may be necessary to reconsolidate our power.

As Lord Morley in his *Life of Gladstone* says, "this pregnant and far-sighted warning seems to have been little considered by English statesmen of either party at this critical time or afterwards, though it proved a vital element in any far-sighted decision."

The result of the general election of 1880 was to place Mr Gladstone in power. The new administration, notwithstanding Mr Gladstone's public utterances, declared their intention of retaining British sovereignty in the Transvaal, coupling with that decision a pious hope for the speedy accomplishment of confederation so as to allow of free institutions being given to Natal and the Transvaal.[2] The disillusionment occasioned by this decision caused the Boer delegates then at the Cape to help to wreck the federation proposals (see *supra*). But if unwilling at the time to undo the work of Sir T. Shepstone, the Liberal cabinet were prepared to get rid of the chief British representative in South Africa—partly to please the extreme Radicals among their followers. Accordingly on the 2nd of August 1880 Frere received a telegraphic despatch from Lord Kimberley (the new secretary of state for the colonies) announcing his recall.[3] Frere's task was one of extreme delicacy; he chose to face difficulties rather than evade them, and had he been unfettered in his action might have accomplished much more than he was able to do; in its main lines his policy was sound. (See FRERE, SIR HENRY BARTLE.)

Recall of Sir Bartle Frere.

Finding that the Gladstone administration would not give up the Transvaal voluntarily, the Boers now determined on rebellion. Hostilities began in December 1880, and eventually a series of engagements ended in the rout (Feb. 27, 1881) of a small British force which had occupied Majuba Hill the previous evening. The killed included the general in command, Sir George Colley. Meanwhile the resolution of Mr Gladstone and his colleagues to keep the Transvaal had been shaken by the Boer declaration of independence. After the first engagements this resolution was further weakened; and when, after a British reverse at Ingogo (Feb. 8), overtures were made by Mr Kruger on behalf of the Boers, the cabinet was strongly inclined to come to terms. The news of Majuba did not turn it from its purpose. Opinions will always differ as to the course adopted by the Liberal government. "We could not," wrote Mr Gladstone, "because we had failed on Sunday last, insist on shedding more blood." It is at all events abundantly clear that had the Boers not resorted to arms they would not have gained the support of the cabinet.[4]

Majuba.

Sir Evelyn Wood, who had succeeded Colley as general in command and governor of Natal, under instructions from home, concluded a treaty of peace on the 22nd of March. The terms agreed upon were elaborated in a convention signed at Pretoria in August following. By this instrument the Transvaal was granted self-government subject to British suzerainty and the control of the foreign relations of the state. In 1884 the Gladstone administration made further concessions by the London convention of that year. This last document still, however, reserved for Great Britain certain rights, including the power of veto over treaties concluded by the Transvaal with any power other than the Orange Free State. But the success of the Transvaal Boers both in war and diplomacy had quickened the sense of racial unity among the Dutch throughout the country, and there arose a spirit of antagonism between the Dutch and the British which affected the whole future of South Africa.

Before, however, dealing with the relations between the British and the Boers subsequent to 1881 brief reference may be made to affairs in which other powers were concerned; affairs which were the prelude to the era of expansion associated with the career of Cecil Rhodes. In 1868 the Europeans in Great Namaqualand and Damaraland petitioned for annexation to Great Britain. Eventually (1878) only Walfish Bay and a small strip of adjacent territory were annexed. In 1883 Germany entered the field and during 1884–1885, owing to the procrastinating policy of the Cape and British governments, all the coast between the Orange and the Portuguese frontier, save Walfish Bay, was placed under German protection (see AFRICA, §5). The eastern boundary of German South-West Africa was fixed in 1890, the frontier running through the Kalahari Desert. Bechuanaland, the region between the German colony and the Transvaal, was secured for Great Britain. It was not on the west coast only that Germany made efforts to secure a footing in South Africa. In September 1884 an attempt was made to secure St Lucia Bay, on the coast of Zululand. Here, however, Great Britain stood firm. St Lucia Bay had been ceded to the British by the Zulu king Panda in 1843, and this cession has always been regarded as valid. Eventually Germany agreed to make no annexation on the east coast of Africa south of Delagoa Bay. With the proclamation of a British protectorate over the coast of Pondoland in January 1885 the coast-line from the

Germany in South Africa.

[1] Had Shepstone's promise been redeemed at an *early* date, it might well have extinguished the agitation for independence.

[2] It is remarkable that the Liberal government, despite this aspiration, and despite stronger language used by Mr Gladstone, did nothing to give the Boers any real self-government. Sir Bartle Frere pressed the new administration, as he had the Conservative government, on this point without effect.

[3] Frere sailed for England on the 15th of September. His successor, Sir Hercules Robinson, reached the Cape at the end of January 1881.

[4] Morley's *Life of Gladstone*, bk. viii. ch. 3, "Majuba."

mouth of the Orange to Delagoa Bay (save for the small stretch of Amatonga shore-line) became definitely British.

To Delagoa Bay, or rather to the southern part of the bay, Great Britain had laid unsuccessful claim. On the northern bank of the chief estuary of the bay the Portuguese had from the 16th century onward maintained a precarious foothold; it was their most southerly station on the east coast of Africa. In 1823 treaties had been concluded by the British with tribes inhabiting the southern shores of the bay. Neither the Portuguese nor the British claims seemed of much importance until the rise of the South African republic. Anxious for a seaport, the Transvaal Boers in turn laid claim to Delagoa Bay. This brought the dispute between Great Britain and Portugal to a head, the matter being referred in 1872 to the president of the French republic for arbitration. In 1875 an award was given by Marshal MacMahon entirely in favour of the Portuguese (see DELAGOA BAY). As a port outside British control Delagoa Bay was a source of strength to the Boers, especially as the railway[1] was under their control. In the war which began in 1899 munitions of war and recruits for the Boers were freely passed through Delagoa Bay.

Delagoa Bay.

C. *The Struggle for Supremacy between British and Dutch.*—Bechuanaland, through which territory runs the route to the far interior—the countries now known as Rhodesia—was acquired, despite the strong desire of the Gladstone administration to avoid further annexations in South Africa. At first the encroachments on Bechuana territory by Boers from the Transvaal were looked upon with comparative indifference. The Boers respected neither the frontier laid down by the Pretoria convention nor that (modified in their favour) drawn in the London convention. But missionary influence was strong; it was reinforced by the growing strength of the imperialistic spirit and by the fears excited by Germany's intrusion on the south-west coast. An expedition was sent out in October 1884 under Sir Charles Warren; the Boers, who had set up the "republics" of Goshen and Stellaland, were obliged to give way, and the country was annexed (see BECHUANALAND). It was in connexion with this affair that Cecil Rhodes first came into prominence as a politician. As a member of the Cape parliament he undertook a mission, before the arrival of Warren, to the Goshen and Stellaland Boers, endeavouring, unsuccessfully, to obtain from them a recognition of British sovereignty. The acquisition of Bechuanaland by Great Britain was the essential preliminary to the development of the schemes which Rhodes entertained for the extension of British rule into Central Africa. In his endeavours to realize this aim he had to contend with the new spirit of national consciousness animating the Boers, which found expression in the formation of the Afrikander Bond.

Bechuanaland Annexed.

In its external, as in most of its internal policy, the Transvaal was controlled from 1881 onward by Paul Kruger, who was elected president of the state in 1883. Yet Kruger was scarcely the real leader in the nationalist movement to which the successful revolt of 1880–81 gave strength. The support given by the Cape Colony Dutch to the malcontent Transvaal Boers has already been mentioned. During the 1880–81 revolt many Free State burghers, despite the moderating influence of President Brand, joined the Transvaal commandoes. Now a definite effort was made to build up a united South Africa on anti-British lines. In the latter part of 1881 a Dutch pastor at the Paarl, a town in western Cape Colony named Du Toit, in a paper called *De Patriot*, suggested the organization of an Afrikander Bond; in the same year Carl Borckenhagen, a German resident in the Free State, advocated such a bond in his paper, the *Bloemfontein Express*. The Bond was formed, its work being almost confined to Cape Colony. It held its first congress at Graaf Reinet in 1882. In the "programme of principles" upon which its constitution was modelled it was set forth that:

The Afrikander Bond.

While in itself acknowledging no single form of government as the only suitable form, and whilst acknowledging the form of government existing at present [the Bond] means that the aim of our national development must be a united South Africa under its own flag.

In the following year the Farmers' Protection Association was amalgamated with the Bond, and the joint organization fell under the control of J. H. Hofmeyr, the leader of the Dutch party in Cape Colony. Under Hofmeyr's politic control all declarations inconsistent with allegiance to the British Crown were omitted from the Bond's constitution. It remained, however, a strong nationalist organization, which in practice was inimical not so much to the British connexion as to the British section of the population and to the development of the country on enlightened lines. (For the Afrikander Bond see further CAPE COLONY: *History*, and HOFMEYR.)

Not long after the Warren expedition the valuable gold fields which Sir Garnet Wolseley had foreseen would be discovered in the Transvaal were actually found. By 1886, the year in which Johannesburg was founded, the wealth of the Witwatersrand fields was demonstrated. The revenue which these discoveries brought into the Transvaal treasury increased the importance of that state. The new industrial situation created had its effect on all parties in South Africa, and in some measure drew together the British and Dutch sections outside the Transvaal. A customs union between Cape Colony and the Free State was concluded in 1889, to which later on all the other South African states, save the Transvaal, became parties. But Kruger remained implacable, bigoted, avaricious, determined on a policy of isolation. In 1887 he made proposals for an alliance with the Free State. Brand refused to be ensnared in Kruger's policy, and the negotiations led to no agreement. (For details of this episode see ORANGE FREE STATE: *History*.) Not many months afterwards (July 1888) the Free State lost by death the wise, moderating guidance of Sir John Brand. The new president, F. W. Reitz, one of the founders of the Bond, in 1889 committed the Free State to an offensive and defensive alliance with the Transvaal. Kruger thus achieved one of the objects of his policy. Within the Transvaal a great change was coming over the population. There flocked to the Rand many thousands of British and other Europeans, together with a considerable number of Americans. This influx was looked upon with disfavour by Kruger and his supporters, and, while the new comers were heavily taxed, steps were speedily taken to revise the franchise laws so that the immigrants should have little chance of becoming burghers of the republic. This exclusion policy was even applied to immigrants from the other South African countries. A system of oppressive trade monopolies was also introduced. The situation with which the Boers were called upon to deal was one of great difficulty. They could not keep back the waves of the new civilization, they feared being swamped, and they sought vainly to maintain intact their old organization while reaping the financial benefit resulting from the working of the gold mines. The wider outlook which would have sought to win the Uitlanders (as they were called) to the side of the republic was entirely lacking. The policy actually followed was not even stationary; it was retrogressive.

Kruger's Hostility to the Uitlanders.

Meanwhile, and partly through distrust of the Kruger policy, there was growing up in Cape Colony a party of South African Imperialists, or, as they have been called, Afrikander Imperialists, who came to a large extent under the influence of Cecil Rhodes. Among these were W. P. Schreiner (afterwards premier of the colony) and J. W. Leonard (sometime attorney-general) and, to some extent, Hofmeyr. From the time of his entrance into politics Rhodes endeavoured to induce the leading men in the country to realize that a development of the whole country could and should be accomplished by South Africans for South Africans. He fully admitted that the cry which had become so popular since 1881 of "Africa for the Afrikanders" expressed a reasonable aspiration, but he constantly pointed out that its fulfilment could most

Afrikander Imperialists.

[1] For the international difficulties connected with the building of the railway from Delagoa Bay to Pretoria see LOURENÇO-MARQUES.

advantageously be sought, not, as the Kruger party and extremists of the Bond believed, by working for an independent South Africa, but by working for the development of South Africa as a whole on democratic, self-reliant, self-governing lines, under the shelter of the British flag. Hofmeyr was among those whom Kruger's attitude drove into a loose alliance with Rhodes. In 1884, having the power in his hands when the Scanlen ministry fell, Hofmeyr had put into office a ministry dependent upon the Bond, and had talked of a possible Dutch rebellion in Cape Colony if the Boer freebooters in Bechuanaland were ejected; in 1890 Rhodes became premier with Hofmeyr's approval and support. Rhodes remained in office as prime minister until January 1896. During these six years the part he played in the development and public life of South Africa was greater than that of any other man. He used his period of power to put into execution his plans for the extension of British dominion over the country up to the Zambezi.

British South Africa Company.

In 1888 Rhodes had succeeded in inducing Sir Hercules Robinson, the high commissioner, to allow J. S. Moffat, the British resident at Bulawayo, to enter into a treaty with Lobengula, the Matabele chief. Under this treaty Lobengula bound himself not to make a treaty with any other foreign power, nor to sell or in any other way dispose of any portion of his country without the sanction of the high commissioner. This step prevented the country from falling into the hands of Germany, Portugal or the Boers. The treaty was followed by the formation of the British South Africa Company, which obtained a royal charter in 1889, and by the occupation of Mashonaland in 1890. Difficulties with the Portuguese followed, but the Salisbury administration firmly upheld British claims, with the result that the British sphere of influence was extended not only to the Zambezi but beyond to the shores of Lake Tanganyika (see AFRICA: § 5). In 1893 a war was fought with the Matabele by Dr L. S. Jameson, then administrator of Mashonaland, and Bulawayo was occupied. The name Rhodesia was conferred upon the country in 1894 (see RHODESIA). Living in Cape Town and at the head of the government, Rhodes used every effort to demonstrate to the Cape Colonists that the work he was doing in the north must eventually be to the advantage of Cape Colonists and their descendants. On the whole, Hofmeyr and his friends were well pleased at having secured the co-operation of the "big Englander" Rhodes, or, as he was at one time called by Mr J. X. Merriman,[1] an old parliamentary hand and treasurer-general during part of Rhodes's premiership, the "young burgher."

Rhodes and the Bond.

In 1891 the Bond Congress was held at Kimberley, and harmony appeared to reign supreme. During his term of office Mr Rhodes addressed himself to bringing together all interests, as far as it was practicable to do so. He showed that his views of the situation were broad and statesmanlike. His handling of the native question in Cape Colony gave general satisfaction. Rhodes was also a firm believer in the federation of the South African states and colonies, and he sought to promote this end by the development of inter-state and inter-colonial railway systems, and the establishment of common customs, tariffs, and inter-colonial free trade under a customs union.[2] The persistent opponent to both these measures was the Transvaal. In matters of domestic legislation, such as taxation and excise, Rhodes fell in to a considerable extent with Dutch prejudices.

First Transvaal Reform Movement.

While in the rest of South Africa there was a growing feeling of trust between the Dutch and British, accompanied by increasing trade and the development of agriculture, the condition of the Transvaal was becoming serious. At first the new-comers to the Rand had submitted to the economic and political burdens to which they were subjected, but as they grew in numbers and found their burdens increased they began to agitate for reforms. In 1892 (the year in which the railway from Cape Town reached the Rand), the National Union was founded at Johannesburg by ex-Cape Colonists of the Imperial progressive party. For three years petitions and deputations, public meetings and newspaper articles, the efforts of the enlightened South African party at Johannesburg and Pretoria, were all addressed to the endeavour to induce President Kruger and his government to give some measure of recognition to the steadily increasing Uitlander population. Urgent representations were also made by the British government. President Kruger remained as impenetrable as adamant. Nine-tenths of the state revenue was contributed by the Uitlanders, yet they had not even any municipal power. By a law of 1882 aliens could be naturalized and enfranchised after a residence in the country of five years, but between 1890 and 1894 the franchise laws were so altered as to render it practically impossible for any foreigner to become a burgher. By the law of 1894 the immigrant must have been at least 14 years in the country and be 40 years old before in the most favourable circumstances he could be admitted to the franchise. The Uitlanders once more petitioned, over 34,000 persons signing a memorial to the Raad for the extension of the franchise. The appeal was refused (August 1895). Up to this period a section of the Uitlanders had believed that Kruger and his following would listen to reason; now all realized that such an expectation was vain. Rhodes, who had large interests in the Rand mines, had consistently endeavoured to conciliate the extreme Boer section in the Transvaal and win it over (as had happened in the case of the Cape Dutch) to a policy which should benefit the whole of South Africa. He was even willing to see the Transvaal obtain a seaport (at Kosi Bay, in Amatongaland) if in return it would join the customs union. This opportunity Kruger let slip; and in May 1895, on the representation of Sir H. Loch, the Rosebery administration annexed Amatongaland, thus making the British and Portuguese frontier conterminous. This action, finally blocking the Boer road to the sea, taken by a Liberal government, was clear indication that Great Britain was determined to maintain her supremacy in South Africa.

The situation in August 1895 was thus one of extreme tension. There had been a change of ministry in Great Britain and Joseph Chamberlain had become colonial secretary. Sir Hercules Robinson, who was regarded sympathetically by the Dutch population of South Africa, had succeeded Loch as high commissioner. Both high commissioner and the imperial government were hopeful that Kruger might even yet be induced to modify his policy; the Uitlanders now entertained no such hope and they prepared to appeal to arms to obtain redress of their grievances. The first proposals for an armed rising came from Rhodes in June, but it was not until November that the Uitlander leaders came to a definite understanding with the Cape premier as to the course to be pursued. To lay before South Africa the true position of affairs in the Transvaal Charles Leonard issued a manifesto as chairman of the National Union. It concluded with a list of demands (see TRANSVAAL), their gist being "the establishment of this republic as a true republic" with equitable franchise laws, an independent judicature and free trade in South African products.

This manifesto, issued on the 26th of December, called a public meeting for the night of Monday the 6th of January 1896, "not with the intention of holding the meeting, but as a blind to cover the simultaneous rising in Johannesburg and seizing of the arsenal in Pretoria on the night of Saturday the 4th of January" (Fitzpatrick, *The Transvaal from Within*, ch. iii.). Had the Transvaal government given way, even at the last hour, the reformers would have been satisfied. Of this, however, there was no expectation. The arrangement with Rhodes included the use of an armed force belonging to the Chartered Company, and led by Dr Jameson. Accordingly some troops were brought from Rhodesia and stationed near Mafeking, a few miles from the Transvaal frontier. For some weeks the plot appeared to progress

The Jameson Raid.

[1] Mr Merriman (b. 1841) was a son of N. J. Merriman (1810–1882), bishop of Graham's Town. He was a member of various Cape ministries from 1875 onwards.

[2] For Rhodes's scheme of commercial federation see further CAPE COLONY: *History*.

favourably. It might have succeeded but for a vital difference which arose between the Uitlanders in Johannesburg and Rhodes. As Charles Leonard's manifesto stated, the reformers as a body, desired to maintain the autonomy of the Transvaal and the republican form of government; Rhodes wished the revolution to be accomplished under the British flag.[1] "I was not going to risk my position," he stated subsequently, "to change President Kruger for President J. B. Robinson" (the only prominent Uitlander who stood aloof from the reform movement). This divergence of views manifested itself on Christmas Day 1895, and although, under pressure, Rhodes did not insist on the British flag, it was determined to postpone the rising. Jameson was so informed, nevertheless he precipitated the crisis by invading the Transvaal on the evening of December the 29th. The Transvaal government, meantime, had obtained some knowledge of what was being projected, and the Raid ended in a forced surrender (January 2, 1896) to a superior force of Boers. The Reform Committee, *i.e.* the Uitlander leaders, after holding Johannesburg for over a week, also surrendered, and by the 9th of January the plot had ended in complete failure. Mr Chamberlain still desired Kruger to grant immediate reforms and propounded a scheme of "Home Rule" for the Rand. The time was inopportune, however, for pressing the Transvaal on the subject, and nothing was done.[2]

The Jameson raid had a profound effect on the history of South Africa. It greatly embittered racial feeling throughout the country; it threw the Free State Boers completely on to the side of the Transvaal; it destroyed the alliance between the Dutch in Cape Colony and the Imperialists led by Rhodes. It did more, it divided British opinion, sympathy for the Boer republics leading in some cases to a disregard for the real grievances of the Uitlanders. It also gave a much desired opportunity for the intrusion of other powers in the affairs of the Transvaal;[3] and it led Kruger to revive the scheme for a united South Africa under a Dutch republican flag. This scheme found many supporters in Cape Colony. A suspicion that the Colonial Office in London was cognizant of Rhodes's plans further excited Dutch national feeling, and the Bond once more became actively anti-British. Rhodes had resigned the premiership of the Cape a few days after the Raid, and during the greater part of 1896 was in Rhodesia, where he was able to bring to an end, in September, a formidable rebellion of the Matabele which had broken out six months previously.

A section of the Dutch population was not however disposed to sacrifice the development of industries and commerce for racial considerations; while sharing the political aspirations of Kruger and Steyn the wiser among them wished for such a measure of reform in the Transvaal as would remove all justification for outside interference. Nevertheless the cleavage at the Cape between the Dutch and British grew. Sir Gordon Sprigg, who had become Premier of Cape Colony in succession to Rhodes, found his position untenable, and in October 1898 he was succeeded by a Bond ministry under Mr W. P. Schreiner. The term "Progressive" was now formally adopted by the British mercantile communities in the large towns and among the sturdy farmers of British descent in the eastern province. On returning to South Africa after the Raid inquiry at Westminster in 1897, Rhodes had intended to withdraw from Cape politics and devote his energies for a time entirely to Rhodesia, but the pressure put upon him by a section of the British colonists was so strong that he determined to throw in his lot with them.

In the Transvaal, meantime, the situation of the Uitlanders grew worse. The monopoly and concessions regime continued unchecked, the naturalization laws were not amended, while the judicature was rendered subservient to the executive (see TRANSVAAL: *History*). The gold mining industry was fostered only so far as it served to provide revenue for the state, and large sums from that revenue were used in fortifying Pretoria and in the purchase of arms and ammunition. This process of arming the republic had begun before the Raid; after that event it was carried on with great energy and was directed against Great Britain. Kruger also sought (unsuccessfully) to have the London Convention of 1884 annulled, and he entered into a closer union with the Free State. Great Britain watched the development of Kruger's plans with misgiving, but except on points of detail it was felt for some time to be impossible to bring pressure upon the Transvaal. The retirement of Lord Rosemead (Sir Hercules Robinson) from the post of high commissioner was, however, taken advantage of by the British government to appoint an administrator who should at the fitting opportunity insist on the redress of the Uitlanders' grievances.

Milner appointed High Commissioner.

Sir Alfred Milner (see MILNER, VISCOUNT), the new high commissioner, took up his duties at the Cape in May 1897. He realized that one of the most potent factors in the situation was the attitude of the Cape Dutch, and in March 1898 at Graaff Reinet Milner called upon the Dutch citizens of the Cape, "especially those who had gone so far in the expression of their sympathy for the Transvaal as to expose themselves to charges of disloyalty to their own flag" to use all their influence, not in confirming the Transvaal in unjustified suspicions, not in encouraging its government in obstinate resistance to all reform, but in inducing it gradually to assimilate its institutions, and the temper and spirit of its administration, to those of the free communities of South Africa, such as Cape Colony or the Orange Free State. Moreover the Graaff Reinct speech showed that Milner was aware of the dangerous policy being followed by the Bond. The Dutch party at the Cape was shown to be incurring a heavy responsibility, especially as its leaders were aware, in the words of Mr J. X. Merriman, of "the inherent rottenness" of the Kruger régime. That party soon afterwards had it in its power to bring pressure officially upon President Kruger, for it was a few months after the delivery of the speech that Mr Schreiner became premier. To some extent this was done—but in a manner which led the Transvaal Boers to count in any event on the support of the Cape Dutchmen. In the Transvaal, as has been said, affairs were steadily going from bad to worse. An Industrial Commission, appointed (under pressure) by President Kruger in 1897 to inquire into a number of grievances affecting the gold industry, had reported in favour of reforms. The recommendations of the commission, if adopted, would have done something towards relieving the tension, but President Kruger and his executive refused to be guided by them. Once more the Uitlanders determined to make a further attempt to obtain redress by constitutional means, and the second organized movement for reform began by the formation in 1897 of a branch of the South African League.

Second Transvaal Reform Movement.

At the end of 1898 the feelings of the Uitlanders were wrought up to fever pitch. The police service, which was violent where it should have been reasonable, and blind where it should have been vigilant, had long been a source of great irritation. On the 18th of December a Boer policeman, in pursuit of an Englishman named Edgar, whom he wished to arrest for an alleged assault on another man, entered his house and shot him dead. The deepest indignation was aroused by this incident, and was still further increased by the trivial way in which the case was dealt with by the court. The killing of Edgar was followed by

[1] In his evidence before the House of Commons Select Committee which inquired into the Raid, Rhodes did not object to the continued existence of the republic "for local matters," but desired a federal South Africa under the British flag; see Blue Book (165) 1897 p. 21; also Sir Lewis Michell's *Life of Rhodes*, vol. ii. ch. xxx.

[2] Jameson and the other raiders were handed over to the British government for punishment. Four of the Reform leaders were condemned to death on the 27th of April, but the sentence was commuted to a fine of £25,000 each. For details of the Reform movement and Jameson Raid see TRANSVAAL: *History*.

[3] Rhodes informed the House of Commons Select Committee that the belief that the Boers intended to introduce the influence of another foreign power in the already complicated system of South Africa "greatly influenced" him in promoting the revolt. Germany at the time of the Raid was prepared to intervene, and on the 3rd of January 1896 the German Emperor, by telegram, congratulated Kruger that "without appealing to the help of friendly powers" the Boers had overcome Jameson.

the breaking up of a public meeting at Johannesburg, and in March the Uitlanders handed to the high commissioner a petition for intervention with 21,684 signatures attached to it (see TRANSVAAL: *History*).

The Case for British Intervention.

On the 4th of May 1899 Sir Alfred Milner felt it his duty to report at some length by cable to Mr Chamberlain. The concluding passages of this message, which summed up the whole South African situation in a masterly manner, were as follows:—

The case for intervention is overwhelming. The only attempted answer is that things will right themselves if left alone. But, in fact, the policy of leaving things alone has been tried for years, and it has led to their going from bad to worse. It is not true that this is owing to the Raid. They were going from bad to worse before the Raid. We were on the verge of war before the Raid, and the Transvaal was on the verge of revolution. The effect of the Raid has been to give the policy of leaving things alone a new lease of life, and with the old consequences.

The spectacle of thousands of British subjects kept permanently in the position of helots, constantly chafing under undoubted grievances, and calling vainly to Her Majesty's government for redress, does steadily undermine the influence and reputation of Great Britain, and the respect for British government within the queen's dominions. A certain section of the press, not in the Transvaal only, preaches openly and constantly the doctrine of a republic embracing all South Africa, and supports it by menacing references to the armaments of the Transvaal, its alliance with the Orange Free State, and the active sympathy which, in case of war, it would receive from a section of Her Majesty's subjects. I regret to say that this doctrine, supported as it is by a ceaseless stream of malignant lies about the intentions of the British government, is producing a great effect upon a large number of our Dutch fellow-colonists. Language is frequently used which seems to imply that the Dutch have some superior right even in this colony to their fellow-citizens of British birth. Thousands of men peaceably disposed and, if left alone, perfectly satisfied with their position as British subjects, are being drawn into disaffection, and there is a corresponding exasperation on the side of the British.

I can see nothing which will put a stop to this mischievous propaganda but some striking proof of the intention of Her Majesty's government not to be ousted from its position in South Africa. And the best proofs alike of its power and its justice would be to obtain for the Uitlanders in the Transvaal a fair share in the government of the country which owes everything to their exertions. It could be made perfectly clear that our action was not directed against the existence of the republic. We should only be demanding the re-establishment of rights which now exist in the Orange Free State, and which existed in the Transvaal itself at the time of, and long after, the withdrawal of British sovereignty. It would be no selfish demand, as other Uitlanders besides those of British birth would benefit by it. It is asking for nothing from others which we do not give ourselves. And it would certainly go to the root of the political unrest in South Africa; and though temporarily it might aggravate, it would ultimately extinguish the race feud, which is the great bane of the country.

In view of the critical situation Milner and Kruger met in conference at Bloemfontein on the 31st of May. Milner practically confined his demands to a five years' franchise, which he hoped would enable the Uitlanders to work out their own salvation. On his side Kruger put forward inadmissible demands (see TRANSVAAL), and the conference broke up on the 5th of June without any result. A new franchise law, on a seven years' naturalization basis, was passed in July by the Transvaal volksraad, but the law was hedged about with many restrictions. Messrs Hofmeyr and Herholdt, the one the leader of the Bond and the other the Cape minister of agriculture, visited Pretoria to reason with Kruger. They found him deaf to all arguments. The fact is that the Boers had made up their minds to a trial of strength with Great Britain for supremacy in South Africa. At the time which from a military standpoint they thought most opportune (October 9) an ultimatum was handed to the British agent at Pretoria, and a war was at once precipitated, which was not to close for over two and a half years. (A.P.H.; F.R.C.)

D. *From the Annexation of the Dutch Republics to the Union.*—An account of the Anglo-Boer War of 1899–1902 will be found under TRANSVAAL. After the surrender of Cronje at Paardeberg (February 1900) to Lord Roberts, Presidents Kruger and Steyn offered to make peace, but on terms which should include the acknowledgment of "the incontestable independence of both republics as sovereign international states"; the Boers also sought, unavailingly, the intervention of foreign powers.

Last Efforts to Preserve the Boer Republics.

The British government had decided that the continued existence of either republic was inadmissible; on the 28th of May 1900 the annexation of the Free State was formally proclaimed, and on the 1st of September the Transvaal was also annexed to the British Empire. A few days later ex-President Kruger sailed from Lourenço Marques for Europe. The refusal of the German Emperor to receive him extinguished alike his political influence and all hopes that the Boers might still have entertained of help from foreign governments. At that time all the chief towns in both of the late republics were held by the British, and the Boers still in the field were reduced to guerilla warfare. Most of the men on their side who had come to the front in the war, such as General Louis Botha in the Transvaal, had been opponents of the Kruger régime; they now decided to continue the struggle, largely because they trusted that the Cape Dutch, and their sympathizers in Great Britain, would be able to obtain for them a re-grant of independence. The Cape Dutch all through 1901 and the first part of 1902 conducted a strong agitation in favour of the former republics, the border line between constitutional action and treason being in many cases scarcely distinguishable. The Cape Afrikanders also formed what was styled a "conciliation committee" to help the party in Great Britain which still supported the Boer side. Messrs Merriman and Sauer went to England as delegates to plead the cause, but it was noted that Hofmeyr refused to join, and the appeal to the British public was a complete failure. The war had indeed stirred every part of the empire in support of the policy of the government, and from Australia, Canada, New Zealand and India, contingents were sent to the front. No terms could be granted which did not include the explicit recognition of British sovereignty. At last the Boer commandos gave up the struggle and on the 31st of May 1902 their leaders signed articles of peace at Pretoria. Henceforth, save for the German and Portuguese possessions, on the west and east coasts respectively, there was but one flag and one allegiance throughout South Africa. With the elimination of the republics one great obstacle to federation was removed; while the establishment of self-government in the new colonies, promised (after a probationary period of "representative institutions") in No. VII. of the peace articles, would give them an opportunity to enter into federal union on equal terms.

The Work of Reconstruction.

The task of founding new and better administrative machinery in the new colonies was left to Lord Milner, and was begun even before the war had ended. The two new colonies were for the time governed on crown colony lines. But the co-operation of the people was at once sought by nominating non-official members to the leglislative councils, and seats on the Transvaal council were offered to Louis Botha, C. J. Smuts and J. H. Delarey. The Boer leaders declined the offer—they preferred the position of untrammelled critics, and the opportunity to work to regain power on constitutional lines when the grant of self-government should be made. Milner had thus an additional difficulty in his reconstruction work. The first necessity was to restart the gold mining industry on the Rand. The Uitlanders, who had fled from Johannesburg just before the war opened, began to return in May 1901, and by the time the war ended most of the refugees were back on the Rand and mining was resumed. A tax of 10% on their annual net produce, imposed in 1902, was the main available source of revenue. The repatriation of some 200,000 Boers followed, and the departments of justice, education and agriculture were remodelled.[1] In all that he did Milner had endeavoured to promote closer union. Thus the railway and constabulary of both the ex-republics were under a single management. In this

[1] To aid him Milner had the services of some of the best men in the British service, *e.g.* Sir Godfrey Lagden, Sir Arthur Lawley, Sir J. Rose-Innes, Sir Richard Solomon. He also secured the help of a considerable number of young Oxford men who became known as "the Milner Kindergarten."

work the high commissioner had the support of Mr Chamberlain, who paid a visit to South Africa which extended from Christmas 1902 to the end of February 1903. He sanctioned the calling of an inter-colonial conference, which led to a customs convention including all the British possessions in South Africa, and to united action regarding railway rates and native questions.[1]

Chinese Labour.

The great expenditure incurred during the war had led to much deception as to the growth of trade, while the large sums spent on repatriation and other temporary work maintained this deception for some time after the war had ceased. But before 1903 had ended it was manifest that this had been a spurious activity, and a period of marked commercial depression, lasting until 1909, ensued. This depression was in considerable measure due to, and was largely aggravated by, the comparative inactivity of the Rand mines, and that inactivity was due in turn to the insufficiency of native labour—Kaffirs being employed to do all the unskilled work on the mines. At the close of 1903 the mine-owners, to meet the deficiency, asked for permission to import Chinese. The consent of the high commissioner and of the home government was obtained, and in June 1904 the first batch of coolies reached the Rand. They came on three-years' indentures, over 50,000 Chinese being eventually brought over. This introduction of Chinese labour met with considerable opposition. The South African objections were economic and racial, based on the results which had followed the introduction of Indian coolies into Natal. In Natal these coolies had been allowed to remain after the completion of their indentures, and had succeeded in practically monopolizing the petty trade of the country. They had also rapidly multiplied, so that by 1904 they were more numerous than the whites in the colony. The introduction of this large alien element, leading from 1895 onwards to the passing of restrictive measures in Natal, was a mistake which South Africans elsewhere had no desire to repeat. But these objections were overcome by regulations which made repatriation compulsory, and which definitely restricted the coolies to unskilled labour in the mines. These regulations also met the objections voiced by Australians and New Zealanders that the country won for Great Britain at such cost had been thrown open to hordes of Asiatics. In Great Britain, however, the restrictive regulations were precisely those which aroused criticism, the objection taken being that the conditions imposed were of a servile character, if they did not actually make the coolies " slaves. " In the attacks made upon the Unionist government this cry was loudly voiced by the Liberal party in England, and in the political campaign which followed, the " Chinese Slavery " issue undoubtedly helped to swell the majority obtained by Sir H. Campbell-Bannerman in January 1906. Milner's own object in assenting to the introduction of the Chinese was—besides aiding to put the gold mining industry on a more stable basis—to obtain revenue for the great task he had on hand, " the re-starting of the colonies on a higher plane of civilization than they had ever previously attained "; and in respect of the working of the mines and consequently in providing revenue the introduction of the Chinese proved eminently successful; but in February 1906 the Campbell-Bannerman administration felt it incumbent to announce that no ordinance imposing " servile conditions " would be sanctioned. The point as to whether the original conditions were or were not servile was never legally tested, for eventually on the grant of self-government to the Transvaal the Botha cabinet decided (June 1907) not to renew the indentures nor to permit any new importation of coolies. The economic situation had in the meantime considerably altered, and the Transvaal was able to bring pressure upon Portugal to permit the recruiting of many thousands more Kaffirs from Mozambique province. By February 1910 the last of the coolies had been repatriated.

The Lyttelton Constitution, 1905.

By the middle of 1904 the high commissioner and Mr Alfred Lyttelton, who had become secretary for the colonies, agreed that the work of reconstruction had so far progressed that steps should be taken to give the Transvaal " representative government. " This decision was made public in July of that year, and was followed by marked political activity. The Boers in the Transvaal, headed by Louis Botha, formed an association which was called *Het Volk* (the people), and in the Orange Colony a similar organization, the *Oranjie Unie*, was formed. On the 31st of March 1905 the text of the new constitution was issued by letters patent. Short of granting full self-government it was of a liberal character. It provided that the legislative council was to consist of not fewer than six or more than nine official members, and, provisionally, of not fewer than thirty or more than thirty-five elected members. Seats were to be allotted on a voters' (not population) basis, and there was to be an automatic redistribution of seats as voters increased or decreased in given localities. These provisions—subsequently adopted in the electoral law of the Union of South Africa—were made to secure equal rights for the British and Dutch sections of the community. The promulgation of the Lyttelton constitution was quickly followed by the retirement of Lord Milner. He left South Africa in April 1905, and was succeeded as high commissioner and governor of the Transvaal and Orange River colonies by Lord Selborne. But before the new constitution could be established a change of ministry in Great Britain put the Liberals in office, with Sir Henry Campbell-Bannerman as premier (Dec. 1906).

Self-government.

A sudden change was now made. Sir H. Campbell-Bannerman, with several of his colleagues in the ministry, held that the annexation of the republics had not been justified, but there was no question now, as there had been in 1881, of a restoration of independence; that matter the Boers themselves had settled by their acceptance of British sovereignty. The Liberal leader held, however, that the Boers should be given self-government at once. Experience, he declared[2] had proved, unfavourable to the working of representative institutions, and it was safer and better to begin with responsible government. Moreover, the cabinet looked forward, without forcing it in any way, to the federation of South Africa. In the Transvaal the burghers of British origin were about equal in number with those of Dutch origin, and the fairly even balance of parties might be held to be a guarantee against retrogression; in the Orange River Colony it was notorious that the grant of self-government meant handing over the control of the country not simply to the Boers, but to that section of them which since the war had exhibited the greatest racial bitterness. In these circumstances the decision of the Liberal cabinet, however generous, was fraught with peril. But the policy of complete trust in the Boers was a bold one, which was justified by success.

The new letters patent instituting self-government in the Transvaal were issued on the 12th of December 1906; the elections were held in February 1907, and gave the *Het Volk* party a clear majority of seven (in a house numbering 69 members) over all other parties. General Botha became premier, with Mr Smuts as colonial secretary. In the Orange River Colony the first elections under the self-government constitution were held in November 1907, and out of 38 seats in the House of Assembly *Oranjie Unie* candidates secured 29. A ministry was formed with Mr A. Fischer as premier and Generals Hertzog and de Wet as prominent colleagues. These triumphs of the Dutch section of South Africans were followed in the general election in Cape Colony early in 1908 by a sweeping victory of the Bond, helped by the suffrages of re-enfranchised rebels. Dr Jameson—who had been premier of the colony since the Progressive victory at the election of 1904—was succeeded as premier by Mr J. X. Merriman, who was regarded as a Bond nominee. Thus, working within constitutional lines, the Dutch Afrikanders had attained in three out of the four self-governing colonies, political supremacy. The situation in 1908 was, however, radically different from that which existed before the war of 1899–1902. Then half the white population of the Transvaal were as " helots "; now the

[1] This action was on the lines of the commercial federation scheme of Cecil Rhodes, who had died in March 1902.

[2] In a speech in the House of Commons, February 19, 1906.

ex-Uitlanders held 26 seats in the Transvaal parliament, and were able to exercise an effective influence over legislation.

Both the war of 1899–1902 and the grant of self-government to the new colonies were necessary preliminaries to the success of any unification scheme, but the causes which now led to the question of closer union being raised were not political but economic. Since the development of the diamond and gold mining industries the coast colonies had unduly neglected their own resources and had relied chiefly on the forwarding trade. Hence there was jealousy and competition between the Cape and Natal and a tendency to use the railways (which were state owned), by means of rebates, to counteract the effects of common customs dues. Then, too, an increasingly important factor was the competition of Lourenço Marques for the Rand trade. In a time of acute trade depression this commercial rivalry was disastrous to the welfare of South Africa. In March 1906 the customs convention was provisionally renewed (on a strongly protective basis, and with preference for British goods) but there was a distinct prospect of a tariff war when the convention expired in 1908. Again it was known that the Transvaal and Orange River colonies on their attainment of self-government would each demand full control of their own resources, to the detriment of the unitary services which Lord Milner had established. There were, moreover, dangerous differences on such questions as Asiatic immigration, the status of natives, mining, agriculture, &c. Thus the antagonism between the various states on economic lines was at the end of 1906 greater than any racial divisions. The leading South African statesmen realized that unless an effort to remedy this condition was made without delay affairs would go from bad to worse. In these circumstances Dr Jameson, as premier of Cape Colony, took the first overt step to reopening the question of federation.[1] In a minute dated the 28th of November 1906 the Cape ministry declared its belief that the questions which were causing so much friction should be capable of solution "by some duly constituted South African authority responsible to all parties in the country," and it appealed to Lord Selborne, as high commissioner, to review the situation in such a manner that the people of South Africa might form a competent judgment on the question. In answer to this appeal, which was backed by the Natal ministry, Lord Selborne drew up a despatch (dated Jan. 7, 1907) in which the whole case for closer union was set forth in a masterly manner. For insight and breadth of view the despatch ranks with that which Sir George Grey drew up in 1858. In the fifty years that had elapsed the case for closer union had become overwhelming and the dangers of isolation much greater. Four or five administrations, the despatch pointed out, were pursuing rival interests, whereas the country had but one interest. Reviewing one by one the questions on which rivalry existed, Lord Selborne showed that the internal self-government which each colony enjoyed accentuated the difficulty of dealing with these questions as a whole.[2] Stability—the thing which South Africa required above everything else—was unattainable so long as there were five separate governments developing different systems in all branches of public life, but no national government with power to harmonize the whole. "The people of South Africa . . . are not self-governing in respect to South African affairs because they have no South African government with which to govern." Only by the creation of a central government could South Africa be wisely and successfully governed.[3]

The Movement for Closer Union.

The opportunity for testing the strength of the movement for closer union came with the meeting of an inter-colonial conference in May 1908 to consider the thorny questions of tariff and railway rates. In the meantime the Jameson ministry had given place to the Bond nominee ministry with Mr Merriman as premier (see CAPE COLONY: *History*), but the movement initiated by Jameson had received the support of the Bond as well as that of the Botha administration. The delegates at the conference were all representative of the parties in power; that is, with the exception of the Natal delegates, they all represented Dutch ideals in politics. Nevertheless they unanimously resolved "that the best interests and the permanent prosperity of South Africa can only be secured by an early union, under the crown of Great Britain, of the several self-governing colonies," and they recommended the calling of a national convention entrusted with the task of drawing up a draft constitution. Thus for the first time for two generations both the chief white races of South Africa were found working in cordial co-operation. No appeal was made to the electorate, but the colonial parliaments rightly interpreted public opinion in endorsing the recommendations of the conference. Delegates representative of all parties were appointed, and the national convention to consider the question of union met at Durban in October 1908.

The National Convention.

The most prominent members of the convention were Sir Henry de Villiers,[4] chief justice of Cape Colony (president), ex-President Steyn (vice-president), Generals Botha, de Wet and Delarey, Messrs Smuts, Schalk Burger, Merriman and F. R. Moor (premier of Natal), Dr Jameson, Sir George Farrar and Sir Percy Fitzpatrick, the last two the leading representatives of the Transvaal Progressives (*i.e.* the ex-Uitlanders). The greatness of the opportunity was rightly stated by the governor of Natal (Sir Matthew Nathan), who declared that the convention might create a commonwealth which should add to and not draw upon the strength of the empire—a commonwealth which in culture as in power would be among the foremost nations of the world. After sitting at Durban for a month, the convention adjourned to Cape Town and concluded its elaboration of a draft constitution by February 1909. The fundamental points which the delegates had to settle concerned (*a*) the basis of parliamentary representation, (*b*) the status of the natives with respect to the franchise, (*c*) the position of the Dutch language, (*d*) the form of government.

The adjustment of tariff and railway rates gave little trouble when once it was agreed to consider the country as a unit. Points (*a*) and (*b*) both concerned the franchise, but each had its separate issue (*a*) raising the question of representation as it concerned the white population only. Suspicions had been raised that the attempt would be made to force union on a Dutch Afrikander basis, which might have resulted had the basis of representation adopted been the total European population. To this the Progressive party would not agree, and they gained support from Botha, Smuts and other prominent Dutch delegates for their contention that "equal rights" could only be secured by making the basis of representation the number of voters as distinct from the number of European inhabitants of any given area. As finally settled, the number of European male adults was chosen as the basis of representation. As the Transvaal and Orange colonies already possessed manhood suffrage, and as the property qualifications in the coast colonies were low, this alteration made little difference. Point (*b*) raised a graver issue still. The Cape delegates found themselves in isolation in advocating the extension of the electoral system which prevailed in their colony, where there was no colour bar to the exercise of the franchise. The merits of the Cape system—to minimize the differences between the white and native races, typified in the declaration of "equal rights to all civilized men"—or that of the opposite system (as warmly advocated by the Natal delegates as by those from the ex-Boer republics), which would keep the native races in permanent inferiority, cannot here be discussed; it may be stated, however, that the admittance of Kaffirs to the franchise in the Cape had not been attended with the evil consequences feared. At the convention a way out of the difficulty—for a time at least—was found in a compromise, namely, that in the state about to be created the franchise in each constituent part should be that which existed before union was effected. Thus in the Cape the Kaffir would have a right to the franchise, but not in the other divisions of the country. Point (*c*) was decided by placing, for all official purposes, the English and Dutch languages on a footing of perfect equality. As to point (*d*) the

[1] A number of members of the Transvaal administration during the Crown Colony period had worked steadily, in private, to promote closer union. Prominent among these men was Mr Lionel Curtis, at that time (1906) assistant colonial secretary.

[2] Lord Selborne wrote in anticipation of the establishment, a few months subsequently, of self-government in the new colonies.

[3] For the text of the despatch and memorandums going into details see the Blue Book (Cd. 3564) July, 1907.

[4] Sir Henry de Villiers (b. 1842), chief justice of Cape Colony since 1874, was created a peer of the United Kingdom in 1910 under the title of Baron de Villiers of Wynburg. He became in the same year chief justice of South Africa.

issue was between a federal and a unitary form of government. Federation was supposed to afford protection to the smaller communities—Natal and the Orange River Colony—and in Natal there was much anxiety lest its interests should be overborne. Nevertheless the advocates of unification gained a complete victory and a form of government was agreed to which made the union of South Africa as close as that of the United Kingdom.

Among the other decisions of the convention were: the choice of Pretoria as the seat of administration and of Cape Town as the seat of the legislature, the renaming the Orange River Colony, Orange Free State Province; the provision of three membered constituencies and of proportional representation and the safe-guarding of the smaller communities by giving Natal and the Orange River colonies more members of parliament than they were entitled to on the voters basis.

The draft constitution was made public on the 9th of February 1909, and was adopted by the Transvaal parliament in its entirety. The Orange River parliament also approved with only slight alterations; the Natal parliament made some amendments, but they were of a minor character. The opposition to union among an influential number of old Natalians—intensely zealous for local independence—was however so marked that it was decided that before Natal was committed to union a referendum on the subject should be taken. Apart from this doubtful attitude of Natal, the chief danger to the draft constitution came from the Cape Dutch. The draft act, with its "one vote one value" principle, its three-membered constituencies and its scheme for proportional representation, threatened Dutch supremacy in the rural districts, and aroused the opposition of Hofmeyr, who secured the passage of amendments through the Cape parliament which destroyed the principle of equal rights. Such was the position when the convention reassembled in May at Bloemfontein to consider the amendment of the various legislatures. Through the firmness of the Transvaal delegates, supported by the Progressives, the principle of equal rights was retained; the concession made to the Cape was the abandonment of proportional representation, while one-membered constituencies were substituted for three-membered constituencies. The document embodying the alterations in the draft act was signed on the 11th of May and the convention dissolved. In June the referendum on union was taken in Natal, and resulted in a complete rout of the separatists. There voted, for the draft act 11,121, against it 3701—majority for union 7420.

Passing of the Act of Union, 1909.

South Africans had thus after seventy years of discord agreed upon union. It was a momentous step, the essential preliminary to that fusion of the white races of South Africa upon which the prosperity of the country depends; and a step rendering easier the ultimate attainment of imperial union. A delegation carried the draft act to England, and, recast in the form of an imperial bill, it was submitted to the parliament at Westminster. The imperial government made but one alteration of consequence—that explicitly placing the control and administration of matters "specially or differentially affecting Asiatics" in the sole control of the union parliament. The bill passed through parliament unaltered, the only jarring note in the debates in either house concerning the exclusion of natives from the franchise (save in the Cape province). This decision was deplored by all parties in the British parliament, but it was recognized that to alter a decision deliberately come to by South African statesmen would wreck the union. The measure, known as the South Africa Act 1909 received the Royal Assent on the 20th of September, and subsequently the 31st of May 1910—the eighth anniversary of the signing of the articles of peace at Pretoria—was fixed as the date for the formal establishment of the Union.

The interval between the passing of the South Africa Act and the establishment of union was employed by the various colonies in putting their houses in order. This task, on the economic side, was rendered easier by the gradual return of commercial prosperity. An agreement between the Transvaal and the Portuguese governments, concluded in April 1909. while the fate of the draft constitution was still in doubt, assigned to Lourenço Marques 50 to 55% of the import trade to the Rand, and (with certain exceptions) provided for free trade in native products between the Mozambique province and the Transvaal. The Portuguese further agreed to facilitate the recruitment of natives in their territory for work in the Rand mines, and in consequence Kaffirs were obtained in sufficient numbers to replace the Chinese coolies as they were repatriated. The agreement was to last ten years, and provision was made for its recognition by the government of the Union. The native protectorates, Basutoland, Swaziland and Bechuanaland had been left by the South Africa Act under direct imperial control. As to Natal and Zululand, there was a disposition to leave to the new government the task of dealing with the natives there but both the Transvaal and Natal adopted an Asiatic exclusion policy which gave rise to much friction. In the Orange River Colony, General Hertzog aroused much opposition by administering the education act in a way which forced the teaching of Dutch in a rather arbitrary fashion. This was a point of importance, inasmuch as, by the Act of Union, elementary education was left (for five years) in the hands of the provinces. The divergence of views was so great that shortly after the union had been established private schools were opened in opposition to those of the provincial administration.

The Union Established.

In the autumn of 1909 it became known that Lord Selborne, whose services in bringing about the union were generally recognized, would not remain to represent the Crown in inaugurating the new form of government, and the choice of the British government fell on the home secretary, Mr Herbert Gladstone (who was in March 1910 created Viscount Gladstone of Lanark) as first governor-general of the Union. Lord Gladstone had the responsibility of summoning the first prime minister of the Union—a task rendered more difficult as the decision had to be taken before the first election to the Union parliament was held. There had been a strong agitation for a coalition cabinet, and negotiations took place to this end between General Botha and Dr Jameson. These efforts ended in failure. They had met with the determined opposition of Mr Merriman (the Cape premier), of the Orange Free State Boers, and of the Bond, which had lost the counsel of Hofmeyr. That typical leader of the Cape Afrikanders had died in London, whither he had gone as one of the delegates to lay the draft constitution before the British parliament. Towards the end of May, Lord Gladstone called upon General Botha to form a ministry, which was constituted from the ranks of the existing cabinets and included Natal ministers as well as strong Boer partisans like Mr Fischer and General Hertzog. Mr Merriman declined to serve under General Botha. The formal proclamation of the Union took place on the 31st of May.

The first general election, held on the 15th of September, was, perhaps inevitably, fought to a large extent on racial lines. The Dutch Afrikander candidates stood as "Nationalists," while their opponents took the name of Unionists. In Natal the British section of the electorate (four-fifths of the whole) preferred to maintain an independent attitude. The elections, which resulted in a Nationalist majority of 13 over all other parties, showed that the Unionists were stronger than had been thought. They secured 37 seats, while 13 were held by Natal Independents. The polls were remarkable for the defeat of three ministers—General Botha (by Sir Percy Fitzpatrick) at Pretoria East, Mr Hull (by Sir George Farrar) on the Rand, and Mr Moor in Natal. General Botha decided to retain office, and seats for him and Mr Hull were found by means of by-elections. Mr Moor was nominated to the senate, as were, among others, Mr W. P. Schreiner and ex-President Reitz (who became president of that body). On the 4th of November the first session of the Union Parliament was opened by the duke of Connaught.

Soc.*, vol. v. pt. 2 (Cape Town, 1898); *Catalogue of the Books relative to Philology in the Library of Sir George Grey*, vol. i. pt. i. *The Dialects of South Africa* (Cape Town, 1858); *Books, Pamphlets and Articles on British South Africa* (Birmingham Free Library, 1901), *Mendelssohn's South African Bibliography* (2 vols. 1910). See also AFRICA: *Bibliography*. (F. R. C.)

SOUTHALL NORWOOD, an urban district in the Brentford parliamentary division of Middlesex, England, suburban to London, 12 m. W. of St Paul's Cathedral, on the Great Western railway. Pop. (1891), 7896; (1901), 13,200. Brickfields, flour-mills and chemical works are established in the district, which is also largely residential. The Grand Junction Canal serves Southall. Cattle markets are held weekly under a grant of William III. The Elizabethan manor-house of Southall remains, and the parish church of Norwood, though greatly restored, has Early English and Decorated portions, a canopied tomb dated 1547 and brasses of the 17th century.

SOUTH AMBOY, a city of Middlesex county, New Jersey, U.S.A., on Raritan Bay at the mouth of the Raritan river, about 27 m. S.W. of New York City. Pop. (1900) 6349 (1700 foreign-born); (1910) 7007. It is served by the Pennsylvania, the Central of New Jersey, and the Raritan River railways. A railway drawbridge and a traffic bridge across the river connect the city with Perth Amboy. South Amboy is an important point for shipments of coal from the Pennsylvania mines. The Pennsylvania Railroad Company and the Susquehanna Coal Company have coal docks here and the latter has great storage yards. Among the city's industries are the mining of clay and sand, and the manufacture of terra cotta. South Amboy, originally a part of South Amboy township (incorporated in 1798), was laid out in 1835, was incorporated as a borough in 1888, and became a city under a general state law in 1908.

SOUTH AMERICA. The early physical history of the South American continent as recorded in the rocks has been extensively obliterated or greatly obscured by the events of its later history. The early land areas are supposed to be only approximately suggested by the present exposures of granite and gneisses. The largest of these old land areas is along the east of the continent, extending with a few interruptions from the mouth of the Rio de la Plata to within a short distance of the mouth of the Amazon river. North of the present Amazon valley and occupying the present highlands of Guiana, north-east Brazil, and south-east Venezuela was another one of these old land areas—a large island or a group of islands. A chain of islands extended from the Falkland Islands along what is now the entire west side of the continent. Upon these ancient shores were laid down the sedimentary beds of the Cambrian seas. At the close of the Cambrian period the continent was elevated, many of the former islands were joined together, and the continental land area was considerably enlarged. The Silurian seas, however, still covered the basin of the Paraguay, extending from the Serra do Mar on the Brazilian coast to the axis of the Andes on the west, and covering at the same time a considerable part of the basin of the Rio São Francisco, filling the straits between the Andes and the Matto Grosso highlands and opening east through the region now occupied by the lower Amazon valley.

Development of the Continent.

During the Devonian period there was a still further enlargement of the continent through elevation and the joining of islands, and the disappearance of the old Silurian sea in the basin of the Rio São Francisco on the east of the continent. In early Carboniferous times the sea still covered a narrow belt through the lower part of the Amazon valley, and part of what is now the Andes lying south of the equator. During Permian times the basin of the Paraguay and the south-east coast of Brazil was covered with lagoons and swamps in which here and there coal beds were laid down. At the close of this period molten lavas broke through the earth's crust and flowed over and buried large areas in what is now Paraguay and south Brazil.

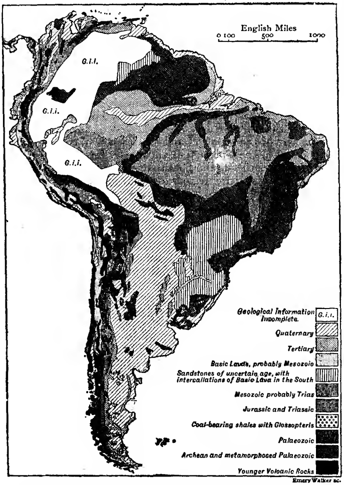
There was a general depression of the continent during the Cretaceous period and the ocean covered most of the continent as we now know it. The Serra do Espinhaço along the east coast of Brazil was above water and the coast line between the Rio de la Plata and Cape St Roque was little different from what it is at present. But through the highlands of Brazil from near Pernambuco west there was a broad sound containing many islands extending to the base of the Andes and possibly connecting with the Pacific Ocean. In the extreme north there were also many islands, bays and sounds, while a continental mass occupied the region of the Antilles. To the south the Atlantic Ocean filled most of the lower Paraguay basin and washed the eastern bases of the Andes. There was shallow-water connexion during this period between South America and southern India, through the Antarctic regions, probably by way of Australia.

In Early Tertiary times great changes took place in the geography of South America. The continent rose much higher than its present elevation, the coast-lines were extended oceanward, and the continent was considerably larger than it is at present. The Abrolhos Islands on the east coast of Brazil were then a part of the mainland and the seashore was some 200 m. further east. The Falkland Islands were also at that time a part of the continent, and South America had land connexion through the Antarctic regions or through the south Pacific Ocean with New Zealand and Australia, and through the West Indies region with Cuba and North America. Toward the close of Tertiary times the continent sank again beneath the ocean and salt water flowed into the Amazon and Orinoco valleys, turning the Guiana highlands again into an island or group of islands, and again separating the continent from land connexion with other continents. The valleys of Rio Magdalena, Rio Cauca and Lake Maracaibo were bays that covered large areas of adjacent territory.

It was during the Tertiary period that the continent took on its most characteristic features. Volcanic activity culminated; the Andes rose from low ridges and islands near sea-level to be one of the greatest mountain systems of the globe. This elevation was partly due to the uplifting of the continent *en masse*, partly to faulting and folding of the rocks, and partly to the pouring out of lavas and the accumulations upon the surface about vents of other volcanic ejectments. This volcanic activity was not confined to the main range of the Andes, but extended into Venezuela and the islands along the north coast, to the plains of Patagonia, the highlands of the Paraná basin and as far east as the islands of Fernando de Noronha. In recent times volcanic activity has greatly diminished over the continent and has entirely ceased along its eastern and north-eastern parts. The great elevation and depression of the continent deeply affected the climate over certain large areas. For example, along the east coast, where winds blew on-shore, the rainfall was greatly increased during the elevation, while the later depression brought about a corresponding diminution of the rainfall. In Pleistocene times the south of the continent stood somewhat lower than it does at present, so that the ocean covered the plains of Patagonia and La Plata. During the glacial epoch the south of the continent and as far north as latitude 27° on the west coast was covered with glaciers that flowed down from the high mountain ranges. On the east side of the mountains the glaciers did not extend so far north as they did on the west side. The glaciers through the high Andes were also larger and longer than they are at present; there were no glaciers in the eastern or Brazilian portion of the continent.

Physical Geography.—The South American continent rises abruptly from the ocean floor along nearly all of its coast, but the steepness of the continental margin is more marked on the western than on the eastern side. From Valparaiso to the Isthmus of Panama, a distance of 3000 m., the great Andes themselves are but the upper or subaerial portions of mountains whose bases are 10,000 ft. below the surface of the Pacific Ocean. South of Valparaiso the 10,000-foot contour lies well out from the coast, but opposite the Straits of Magellan it approaches within 150 m. of the coast-line. On the east side of the continent the 1000-foot contour passes to the east of the Falkland Islands showing that this group stands upon a submerged shelf or shoulder of the continent. From the mouth of the Rio de la Plata northward the 1000-foot submarine contour keeps at a distance of from 50 to 150 m. off the shore nearly to Bahia, Brazil; from Bahia northward and around Cape St Roque this same contour is close inshore, and the ocean-floor sinks abruptly to a depth of 5000 ft. North-west of Cape St Roque the continental shelf of shallow waters widens until opposite the mouth of the Amazon the 1000-foot contour is 300 m. off the coast. The broad shelf follows along this part of the coast as far as the island of Trinidad, west of which it narrows, though the islands along the northern shores of Venezuela all stand upon and form parts of this shallow continental shelf.

Submarine Relief.



The striking features of the land relief of South America are: (1) The great Andean mountain chain with its accompanying narrow plain lying between it and the Pacific Ocean. (2) The Brazilian plateau with the Serra do Mar and Serra do Espinhaço near the Atlantic and spreading westward and northward to the heart of the continent. (3) The highlands of Guiana and Venezuela between the Orinoco and the mouth of the Amazon. (4) The lowlands that spread out along the three main lines of continental drainage, namely the Orinoco, the Amazon and the Paraguay basins.

Land Relief.

The physical features of the west coast are bold, and, in many parts, extremely picturesque. From Cape Horn, where the peaks of the submerged southern end of the Andes form the islands of Tierra del Fuego to the Isthmus of Panama, the great Cordillera follows the coast-line closely and at an even distance from it. The low coastal belt between the ocean and the mountains has an average width of about 40 m., and on rare occasions, when the weather is favourable, the mountains are visible from the sea nearly all the way from the Straits of Magellan to Panama. South of 41° S. the coast is characterized by a vast system of fjords and islands, probably produced by the recent submergence of a mountain system and the consequent invasion of its steep-sided valleys by the ocean. The many islands along this part of the coast, including Chiloe Wellington and the Tierra del Fuego group itself are but the high portions of these mountains that have remained above water, while Smyth Channel and the other sounds on the west coast and the Straits of Magellan 400 m. long and 4 to 20 m. wide, are the submerged valleys. In Smyth Channel at many places the glaciers flow nearly or quite down to sea-level. Some of the islands are steep-sided, barren and uninhabited peaks rising to an elevation of 4000 ft. above sea-level. North of 41° S. the west coast is but little indented, and there are but few good ports. Along the northern part of the continent from Guayaquil to Panama the coastal belt is covered with tropical vegetation; but from a little south of Guayaquil to 30° S. much of the coast is a sandy, arid and barren alkali desert. Across this arid belt flow the streams that descend from the high mountains, and along these are fertile valleys. Many of the smaller streams, however, do not reach the sea but dry up on their way across the arid coastal plain.

The Cordillera is a broad ridge upon which rise many great isolated peaks. Near its northern end the range divides: one branch, the Western Cordillera, continuing northward near the coast; the Merida branch swings eastward and ends with the northern side of the island of Trinidad, while a third division, the Sierra de Perija, runs northward between the valley of the Magdalena and Lake Maracaibo. The western slope of the main Cordillera is steep, and is scored by narrow steep-sided valleys; the eastern slope is usually more gentle, and the valleys are less precipitous. Upon the Cordilleran ridge rise many of the highest peaks in the world. The following are some of the most noted, with their elevations.[1]

Peak.	Country.	Elevation.	Snow-line (approximate).
		ft.	ft.
Aconcagua . . .	Argentina	23,080	17,500
Mercedario . . .	Argentina	22,315	—
Tupungato . . .	Argentina	21,550	—
Illampu (Sorata) . .	Bolivia	21,500	—
Illimani	Bolivia	21,030	—
Chimborazo . . .	Ecuador	20,545	16,700
Juncal	Chile	20,180	—
Cotopaxi	Ecuador	19,613	15,500
Antisana	Ecuador	19,335	16,000
Cayambe	Ecuador	19,186	15,000
Tolima	Colombia	18,300	—
Misti	Peru	17,934	—
Maipo	Argentina	17,670	—
Sierra de Santa Marta	Colombia	16,640	—
Pichincha	Ecuador	15,918	—

The snow-line of the mountains is generally lower on the east than on the west side. Of the Andean peaks those of Cotopaxi, Tungurague, Maipo and Sangai are the highest active volcanoes in the world. There are many glaciers in the Andes even beneath the equator itself; and though these glaciers are small and mostly confined to the highest peaks, toward its southern end along Smyth Channel and in the Straits of Magellan, they are large and flow far down the slopes, and at several places enter the sea.

The eastern side of the continent is in strong physical contrast with the western. North of the Strait of Magellan the coast is flat as far as the northern part of Rio Grande do Sul. From latitude 29° 30′ to 19° 30′ the Serra do Mar makes this the most picturesque portion of the east coast of South America. The mountains rise in many places directly from the seashore to an elevation of 2000 ft. In places these form bare granite walls, while in others they are covered from base to summit with the most luxuriant tropical vegetation. On this part of the coast are some of the finest and most beautiful harbours in the world, notably those of Rio de Janeiro, Santos and Victoria, formed by a depression that submerged the coastal valleys.

The range or group of mountain ranges known under the general name of Serra do Mar falls away toward the north and west in a gently sloping plateau commonly called the Brazilian highlands. On this Brazilian plateau the highest points of which the elevations are known are as follows:—

Peak.	Brazilian State.	Elevation.
		ft.
Itatiáya	Rio de Janeiro	9823
Itajúba or Tembé . .	São Paulo	7800
Organ Mountains . .	Rio de Janeiro	7321
Frade	Espirito Santo	6770
Caraça	Minas Geraes	6412
Itambé	Minas Geraes	5959
Itacolomí.	Minas Geraes	5748
Pyreneos	Goyaz	4536

North of latitude 20° the high mountains swing inland and the coast is low as far as latitude 17° 25′; north of this the coast is

[1] Various authorities differ in their estimates of these elevations.

Reproduced From Original Colorprints By The Gill Engraving Co. N.Y.

bordered by a wall of brightly coloured bluffs from 50 to 250 ft. high which continue with occasional interruptions to the mouth of the Amazon. About Cape St Roque the coast is covered with sand dunes. From the Abrolhos Islands northward to longitude 37° west of Cape St Roque, there are many coral reefs, some of them several miles off shore and many miles in length and breadth, while in other places they follow the coast-line for a hundred miles or more with a few interruptions, now touching the shore, and now standing out two or three miles from the land. Along the parts of the coast where the coral reefs occur are also reefs of hard sandstone that are often mistaken for coral reefs. These stone reefs stand like artificial walls or breakwaters across the mouths of the smaller rivers and the choked up valleys, and thus form several important ports on the north-east coast: such are the ports of Pernambuco, Natal, Porto Seguro, and others of minor importance. North of the mouth of the Amazon the coast is low, much of it is swampy, and all of it is forest-covered as seen from the ocean. This low coast extends as far north and west as the headland north of the Gulf of Paria where the Merida or Venezuelan branch of the Andes reaches the sea.

In southern Venezuela and Guiana and northern Brazil is a plateau commonly known as the Guiana highlands, above which rise several peaks.

Peaks.	Elevation. ft.
Roraima	8740
Ouida	8500
Maraguaca	8230
Turagua	6000

This highland region is mostly forest-covered, but it contains also large areas of open grass-covered plains.

Earthquakes occur throughout the entire length of the Andes; the shocks are sometimes of sufficient violence to do serious damage to cities and towns and to destroy many lives. Such disturbances are almost unknown along the Brazilian side of the continent.

Islands. The eastern coast of South America has remarkably few islands, and these are mostly small, except Trinidad off the coast of Venezuela and the islands of the Marajó group in the mouth of the Amazon. Trinidad (area 1755 sq. m.) is separated from the continent by the Gulf of Paria. Along the northern edge of the island is a range of mountains about 3000 ft. high, which are geologically the eastern end of the Cumana range of the Venezuelan mainland. On the south side of this island is the famous pitch lake—the most extensive deposit of asphalt known. West and north of Trinidad, and lying farther off the coast, are several small islands of historical interest and commercial importance: Tobago, Margarita, Blanquilla and the Curaçao group. Off Cape St Roque (230 m.) is the small Fernando de Noronha group of volcanic islands. The main island has an area of only 12 sq. m. Though this island is separated from the mainland by a channel 13,000 ft. deep, it really stands upon the submerged corner of the South American continent. The Rocas is a small island 80 m. west of Fernando de Noronha. The Falkland Islands in lat. 51° cover an area of 6500 sq. m.; their shores are indented by long tortuous channels that have the appearance of having been made by the depression of a hilly land surface. One of these channels separates the two main islands. Mt Adams, the highest peak on the group, has an elevation of 2300 ft. The group stands upon the submerged edge of the continent, from which it is separated by a shallow sea. Its flora and fauna show that it was formerly a part of the mainland. The Tierra del Fuego group of islands, as well as the many islands both large and small that border the west coast as far north as latitude 42°, are all the higher portions of the continental margin left above water when this part of the continent was depressed. The islands of Juan Fernandez in the same latitude as Valparaiso, and the Galapagos group immediately under the equator are the only others on the west coast worthy of mention.

Rivers. The Amazon, the Orinoco and the Paraguay or La Plata river systems jointly drain an area of 3,686,400 sq. m. Less imposing but yet large and important streams are the Magdalena in Colombia, the Essequibo in British Guiana and the São Francisco in Brazil. The Amazon (properly the Rio das Amazonas or river of the Amazons) and its tributaries is not only the largest of the South American rivers, but it is the largest in the world. The total navigable length of the main stream from Pará to the head of navigation on the Huallaga in Peru is 3000 m.; and this does not include the hundreds of navigable parallel side channels that accompany the main stream from its mouth almost to the mouth of the Javary. Above the falls again these streams are all navigable for long distances. Except at Obidos the Amazon is nowhere confined to a single channel, but it spreads over a vast flood-plain and flows with a sluggish current through thousands of side channels that anastomose with each other, so that one unfamiliar with the stream cannot distinguish the main channel. At several places the river is so wide that one looking across it sees a water horizon as if at sea. Much of the region is more like a great fresh-water sea filled with islands than an ordinary valley with a river running through it. For the most part the land along the stream is low, flat, marshy and at times under water. At a few places, however, notably at Ereré, Obidos, Velha Pobre, Parú, Paraua-quára and Almeirim table-topped hills are visible from the river. The banks of the stream and of its side channels are everywhere covered with a dense forest. The valley, however, is not all forest-covered. From near the Oyapok on the Guyana frontier a series of open grassy campos, interrupted only by the wooded banks of streams, follow along the north side of the Amazon for about 500 m. and extend into British Guiana and the region of the headwaters of Rio Branco. The upper Amazon basin opens broadly northward connecting with the Orinoco drainage across a low watershed, while on the south it is separated by a low divide from the Paraguay basin. The Orinoco rises in the highlands between Venezuela and Brazil, flows westward and northward around this elevated region and then flows eastward into the Atlantic. Along its lower course the banks of the stream are covered with dense forests; in its upper course the mountainous highlands are visible along its right bank, while on its left are vast stretches of flat, treeless, grass-covered plains that extend to the foot-hills of the Cordillera de Merida. The main stream is navigable during a part of the year for a distance of 1000 m. or more.

Under the name of Rio de la Plata may be included the Uruguay and the Paraguay, which enter the ocean through the La Plata estuary, and the Paraná which is the most important branch of the Paraguay. It is a noteworthy feature of the streams entering the Paraguay or La Plata basin that many of those flowing from the arid regions on the west are more or less brackish, while those from the rainy forest-covered regions of Brazil are all fresh-water streams. The upper Paraguay is a sluggish stream winding through grass-covered plains dotted over with palm trees. Above rise a few isolated peaks like so many islands in a great lake. The Gran Chaco is a vast plain, almost perfectly flat, covered with rank vegetation and much of it with water, lying along the west side of the Rio Paraguay in northern Argentina and in Paraguay.

The São Francisco, the largest river that lies wholly in Brazil, rises in the highlands of Minas Geraes in latitude 21° and flows north-eastward parallel with the coast until it reaches latitude 9° 30′ where it bends sharply to the right and enters the Atlantic. It flows entirely through a hilly or mountainous country. It is navigable along its lower course nearly to the falls of Paulo Affonso, 140 m. from its mouth, and also above the falls. In Colombia the Magdalena is a crooked muddy stream about 2000 m. long and navigable as far as Honda.

Lakes. Most of the lakes of South America are mountain lakes in the Andes or along its base. Lake Titicaca in Bolivia is, in respect of elevation and position, the most remarkable of its size in the world. Its surface is 12,545 ft. above sea-level, it has an area of nearly 5000 sq. m. and a maximum depth of 700 ft., and never freezes over. This lake discharges into a marsh that is supposed to have no outlet. Lake Junin or Chinchaicocha on the plateau east of Lima has an altitude of 13,380 ft., and covers an area of 200 sq. m. Along the eastern base of the Andes in southern Argentina is a series of lakes whose basins were probably made by the glaciers that formerly flowed down from the mountains on the west. There are many lakes, both large and small, scattered over the flood-plains of the great rivers of South America, but these are mostly phases of river development. Along the coast-lines there are also occasional lakes of brackish water produced by the depression of the coast and the closing of the open mouths of estuaries thus formed, or by sand barrier beaches thrown up by the sea. Such is Lagoa dos Patos in southern Brazil and many smaller ones on the Brazilian coast. Lake Maracaibo on the coast of Venezuela is a large narrow-necked bay like those of Rio de Janeiro and Bahia, rather than a true lake.

Flora.—The warm, wet, tropical portions of South America are especially favourable to the development of plant life. This continent has therefore furnished an unusually large number of the world's useful plants. Among these are several valuable woods, rubber-producing plants, cotton, potato, tomato, mandioca, pineapple, maize, cinchona, ipecac, vegetable ivory, coca, the chocolate plant and Paraguayan tea. Other tropical and sub-tropical plants such as coffee, sugar-cane, oranges and bananas have been introduced and are extensively cultivated. The flora of the continent embraces a large number of peculiar types that originated either in the highlands of Brazil or in the Andes.

The flora of the Amazon valley may be taken as the type of that of the moist tropical valleys. The forests are so dense, rank and matted with undergrowth as to be almost impenetrable. Palms are the most characteristic and beautiful trees, and reach their greatest development in the Amazon region. They take on a great variety of forms: some have trunks 100 ft. and more in height while others have no trunks at all, but spring like tufts from the ground; some are two feet or more in diameter, while others are as slender as a lead pencil. Bamboos grow to an enormous size and form dense thickets along certain streams. The shaded portions of the forests frequently abound in beautiful ferns, some of which are so small as to be almost microscopic, while others reach the dimensions of trees. For the most part the plants of the open campos have a stunted appearance and the grasses are wiry and tough.

A noteworthy feature of these tropical forests is that they are seldom made up of trees of a single species or of but few species. In the high table-lands of southern Brazil, however, the araucarian pine grows in beautiful forests as far north as Barbacena in the highlands near the headwaters of Rio São Francisco. In the north-west of the continent the western slopes of the Andes are covered with a dense tropical vegetation, while on the east the slopes are comparatively bare. In the high mountains the flora is scanty and bears a general resemblance to that of the temperate regions; 60% of the genera are like those of the temperate zones, but the species are peculiar to the Andes. In the south of the continent plant life is necessarily less tropical.

Fauna.—The fauna of South America includes a large number of species but relatively a small number of individuals. With local exceptions this seems to be true of all the forms of life within the tropical portions of that continent. The land mammals are nearly all small; the tapir is the largest of them, and is found only in the northern two-thirds of the continent. There are many species of monkeys, all of them arboreal in their habits. The only reptiles that are at all abundant are lizards, and in some places alligators. The alligators do not extend south of the La Plata region. Of snakes only the boa constrictor and the water boa are large, and these, like all other kinds, are not abundant. Certain ruminants having long woolly hair are found only in the high Andes; these are the llamas, alpacas and vicuñas. The llama has been domesticated and is used for carrying small burdens. The condor, the largest living bird of flight, inhabits the lofty Andes. The insects of the highest mountains are related generically, but not specifically, to those of the temperate latitudes of North America—a fact understood by biologists to mean that there has been no migration across the intermediate region since the glacial epoch. Owing to temperature and climatic conditions the life forms of the high Andes, whether animal or plant, are more nearly related to those of the lower regions to the south than to those of the lower regions to the north.

The fresh-water fish fauna of the Amazon region is the richest in the world. The distribution of species shows that there has long been direct communication between the drainage of the three great river systems, namely, the Orinoco, the Amazon and the Paraguay.

Inhabitants.—At the time of the discovery of the South American continent by Europeans, the races inhabiting it differed greatly among themselves in customs, languages and civilization. They had then generally developed the arts of spinning, weaving and the manufacture of pottery, and locally were skilled in certain kinds of metallurgy, sculpture, architecture and agriculture. These aboriginal peoples have necessarily been profoundly affected by the invasion of European races and the importation of African races, but in some localities their descendants still form the bulk of the population, and the native American languages are still spoken

Immediately after the discovery of South America the western and northern portions of the continent and the region of the Rio de la Plata began to be colonized by Spaniards, while the eastern portion was colonized by the Portuguese. To these races were added Africans, for many years imported as slaves, especially into Portuguese territory. Of late there has also been a large immigration of Italians into Argentina and southern Brazil. In Argentina about 18% of the population is foreign-born, and of these 56% are Italian, 22% Spanish and 11% French. In Chile only 2·3% of the population is of foreign birth.

Spanish is the language of the country from the eastern end of Venezuela through all the northern and western parts of the continent and over a large part of the Paraguay basin. Throughout Brazil, which covers little less than half of the entire continent, the language is Portuguese. South America is therefore pre-eminently a Latin continent; its few British, Dutch and German colonies count for less in the great ensemble of its population than do the depleted aboriginal races themselves.

Political Geography.—The continent was first visited by Europeans in 1498, when Columbus upon his third voyage touched at the mouth of the Orinoco. Other navigators shortly followed and sailed along the northern and eastern coasts, and by 1509 the coast had been visited as far south as the Rio de la Plata. In 1513 Balboa discovered the Pacific Ocean in the Gulf of Panama, and in 1520 Magellan (properly Magalhães) passed through the straits of Magellan and crossed the Pacific Ocean. Inland the earliest explorations followed the Amazon river, but aside from the discovery of the size, course, and character of the river and its immediate shores, they were of but little importance. Great impulse to exploration and development was given by the silver mines of Peru and later by the discovery of gold and diamonds in the highlands of Brazil.

Discovery.

The early settlement of South America by Europeans began shortly after the discovery of the continent. These settlements were originally colonies under the control of Spain and of Portugal, and they remained for some time dependencies of the mother countries. Eventually, however, they became independent. For many years most of these countries were more or less disturbed by internal dissensions and revolutions, but in process of time, and as industries and commerce have become better established, the governments have become more stable.

The political divisions of the continent are best seen upon an ordinary map, and verbal descriptions of them are therefore omitted. Brazil is the largest and most important single country. The bulk of the remainder is divided into several Spanish-speaking republics that border the continent from Venezuela on the north to Patagonia on the south, while between Venezuela and the Brazilian frontier on the north-east are three comparatively small countries known as British Guiana, Dutch Guiana and French Guiana. These Guianas are the only places at which colonies under European control are established on the mainland of South America. There are, however, a few islands that belong to European countries, such as Trinidad, Tobago and the Falkland Islands to Great Britain, and Curaçáo, Buen Ayre and Oruba to Holland.

Industries and Commerce.—The industry that gave the first great impetus to the settlement of South America by Europeans was mining. The silver deposits of the Andes awakened the cupidity of adventurers shortly after the discovery of the continent, and large numbers of Spaniards poured into that region. The mining of silver that had begun in that part of the world in prehistoric times has continued down to the present day. The Potosi mines of Bolivia are supposed to have yielded in all over a billion and five hundred million dollars' worth of silver. The guano of the coast of Peru and the nitre beds of Chile are now, and have long been, among the most important and valuable natural deposits of the kind in the world. In the world's production of borax Chile ranks third; in the production of tin Bolivia ranks third.

Mining

In 1693 gold was found in the highlands of Brazil, and within a few years Minas Geraes (" General Mines "), as the mining district was called, came to be the leading gold-producing region of the world. The mines reached their greatest productiveness between 1752 and 1761, when the annual yield was worth about six million dollars. During the early period most of the gold came from placer washings. Many mines in the hard rocks have been opened, some have been worked out and exhausted, and some are still in operation. The total gold production of all South America for the year 1895 was estimated at about $13,000,000.

In 1729 or possibly a little earlier diamonds were also discovered in the gold districts of Brazil, and a fresh impetus was given to European immigration and to the importation of African slaves to work the mines. From that time down to the discovery of diamonds in South Africa Brazil was the leading producer of diamonds in the world. The diamonds are found in three widely separate districts: in the state of Minas Geraes in the vicinity of Diamantina, in the state of Bahia in the vicinity of Lençóes, and on the headwaters of the Paraguay river in the state of Matto Grosso. The Bahia region also produces carbonados, or the black diamonds used in the manufacture of diamond drills. The best estimate possible places the market value of the diamond production of Brazil from 1729 to 1885 at $100,000,000. Of late years Brazil has led the world in the production of monazite, which occurs on the coast of Bahia in the form of beach sands. In 1905 the output of manganese by Brazil was second only to that of Russia. There are enormous deposits of iron ore in Minas and São Paulo, though but little developed at present. The agates of southern Brazil are famous.

The forest industries are chiefly such as depend upon the natural products of tropical forests. They include the gathering of rubber, cacáo, coca, ipecac, balsam copaiva, cinchona bark, palm fibre (piassába), brazil-nuts and Paraguay tea. The bulk of the world's supply of cacáo comes from Ecuador, Brazil, Venezuela and Colombia. There is much wood suited for fine cabinet work, but the facilities for supplying such woods are limited. The agricultural industries are chiefly those suited to tropical countries. Those that have reached the greatest development are the growing of sugar cane and the manufacture of sugar, and the growing and preparation for market of cotton, coffee and tobacco. Sugar is made mostly near the sea-coast from near Rio de Janeiro northward along the eastern side of the continent. Cotton is grown in the interior from Bahia northward, while the chief coffee-producing region is in the Brazilian states of São Paulo, Rio de Janeiro, Minas, Espirito Santo and Bahia. Wheat is one of the chief agricultural products of the Argentine Republic. The most important pastoral industries are in the region about the Rio de la Plata, where wool growing and stock-raising have reached a marvellous development.

Forests and Agriculture.

The manufacturing industries are necessarily not so well developed as those of older countries. In the early history of the South American colonies the home countries were interested in the building up of an export trade, and manufacturing in the colonies was therefore discouraged, even by

Manufactures.

direct legislation, while trade with other than the parent countries was prohibited. For some time after the independenee of the new countries, facilities for manufaeture and transport were poor, while the laek of established commercial relations and facilities retarded their growth. The development of manufacturing industries has been more marked of late years, though internal development is still retarded by the lack of highways.

Foreign Commerce. The exterior commereial relations of South America were at first naturally and necessarily with Spain and Portugal. In time other European countries established relations with the rising South American cities, the relative importance of Spain and Portugal in South American commerce has greatly diminished, and the bulk of trade is now with other eountries.

Exports and Imports of Three South American Countries
(In millions sterling, annually *c.* 1906–1910.)

	Rubber	19
Chile	Nitrates	17
	Copper	2

Settlement.—The eontinent as a whole is but sparsely settled. The total population in 1905 was reckoned to be 38,482,000. About half of it, including all the most inaecessible portions, had a population probably not much exceeding what it had at the period of the discovery. It averaged five persons to the square mile, while in North America it was 13 and in Europe 104 to the square mile. The most thickly populated parts are on and near the sea-coast. On the east seaboard a more densely populated narrow belt follows the coast from near Natal just south of Cape St Roque to and south of Buenos Aires. About the eities of Perrambuco, Bahia, Rio de Janeiro, São Paulo, Rio Grande do Sul, Montevideo and Buenos Aires the areas of greater density widen, and, in some instanees (notably near Rio de Janeiro, São Paulo and Buenos Aires) extend inland for several hundred miles. The considerably populated belt begins on the west coast about latitude 42° and follows northward and eastward to the island of Trinidad on the Venezuelan coast, though there are stretches of eoast almost entirely uninhabited. Several of the largest eities of South Ameriea compare favourably with the finest cities of Europe. The best streets of Rio de Janeiro, Montevideo, Buenos Aires and Valparaiso are among the most attraetive in any part of the world. The large cities are all well supplied with water, lighted with eleetricity, possess facilities for transport and are supplied with publie libraries, museums of science and arts and edueational institutions.

Communications.—The commercial relations of South Ameriea with the outside world are maintained by a large number of regular and well-equipped lines of steamers running between its ports and European ports. There is also a large freight business done by steamers sailing at irregular periods, and by sailing vessels. Connexions with the interior of the eontinent were for a long time eonfined to navigation along the principal streams and to tedious overland travel on horseback along almost impassable trails. Sinee 1858, however, when the first 30-m. section of the Dom Pedro II railway from Rio de Janeiro to Queimados was opened, railways have extended far inland and even across the Andes. The boring of the tunnel completing railway connexion between Buenos Aires and Valparaiso was eompleted in November 1909. Railway building has been especially active in Brazil and in the Argentine Republie. From Rio de Janeiro and São Paulo lines now penetrate the highlands of Minas Geraes, while from Buenos Aires they cover the most productive portions of the Argentine Republic, and bring some portions of the interiors of these eountries into close communieation with all parts of the world. In the meanwhile river and eoastwise navigation has greatly developed.

The railway mileage of the various eountries was approximately as follows in 1906:—

	Miles of Railway
Argentine Republie	11,460
Bolivia	700
Brazil	10,408
Chile	2,800
Colombia	411
Ecuador	125
Paraguay	156
Peru	1,146
Uruguay	1,210
Venezuela	529

SOUTHAMPTON, EARL OF, an English title borne by the families of Fitzwilliam and Wriothesley. In 1537 Sir William Fitzwilliam (*c.* 1490–1542), lord high admiral of England, was created earl of Southampton. A son of Sir William Fitzwilliam of Aldwarke, near Rotherham, Fitzwilliam was a companion in boyhood of Henry VIII., and was knighted for his services at the siege of Tournai in 1513. Later he was treasurer of Cardinal Wolsey's household, and was sent several times to France on diplomatie business. As vice-admiral he commanded a fleet when England and France were at war in 1523. He was comptroller of the royal household, chaneellor of the duchy of Lancaster, and keeper of the privy seal. He went to Calais to conduct Anne of Cleves to England and wrote in flattering terms to Henry about his bride. While marching with the English army into Seotland he died at Newcastle in October 1542. He left no sons and his titles became extinct.

In 1547 Thomas Wriothesley (1505–1550) was created earl of Southampton. Entering the serviee of Henry VIII. at an early age, Wriothesley soon made himself very useful to his royal master, and he was riehly rewarded when the monasteries were dissolved, obtaining extensive lands between Southampton and Winchester. Having been on errands abroad, he was made one of the king's principal secretaries in 1540, and was knighted in the same year; in spite of the fall of his patron, Thomas Cromwell, he rose higher and higher in the royal favour, and in 1542 it was said that he almost governed everything in England. He sought to bring about an alliance between England and

Spain in 1543, and was created Baron Wriothesley of Titchfield in 1544. Having been lord keeper of the privy seal for a few months, he became lord high chancellor in 1544, in which capacity he became notorious by his proceedings against Anne Askew. He was one of the executors of Henry's will, and in accordance with the dead king's wishes he was created earl of Southampton in February 1547. However, he had committed an offence in appointing four persons to relieve him of his duties as lord chancellor and advantage was taken of this to deprive him of his office in March, when he also ceased to be a member of the privy council. Again in the council Southampton took a leading part in bringing about the fall of Somerset, but he had not regained his former position when he died on the 30th of July 1550. His successor was his son, Henry (1545–1581), the 2nd earl, one of the Roman Catholic nobles who conspired for the release of Mary Queen of Scots. He died on the 4th of October 1581 and was succeeded by his son, Henry, the 3rd earl (see below).

For the career of the 1st earl see Lord Campbell, *Lives of the Lord Chancellors*; E. Foss, *Judges of England*; and the various state papers and letters of the reign of Henry VIII.

The 3rd earl was succeeded by his son Thomas (1607–1667) as 4th earl. When the dispute began between the king and the parliament he took the side of the latter, but soon the violence of its leaders drove him into the arms of Charles, one of whose most loyal advisers he remained thenceforward. He was however very anxious for peace, and treated on behalf of the king with the representatives of the parliament in 1643, and again at Uxbridge in 1645. Having paid over £6000 to the state, Southampton was allowed to live unmolested in England during the Commonwealth period, and on the restoration of Charles II. he was made lord high treasurer. As treasurer he was remarkable for his freedom from any taint of corruption and for his efforts in the interests of economy and financial order. He died without sons on the 16th of May 1667, when his titles became extinct. Much of his property passed to his eldest daughter Elizabeth (d. 1693), wife of Edward Noel, 1st earl of Gainsborough (1641–1689). The name of the earl is perpetuated in London in Southampton Row and Southampton Street, Holborn, where his London residence stood. After the death of Lady Gainsborough the London property of the earl passed to her sister Rachel, wife of William, Lord Russell, the patriot, and later to the dukes of Bedford.

In 1670 the mistress of Charles II., Barbara, countess of Castlemaine, was created duchess of Cleveland and countess of Southampton. Her son, Charles Fitzroy (1662–1730), was created duke of Southampton in 1675, this title becoming extinct when his son William died in May 1774.

The barony of Southampton was created in 1780 in favour of Charles Fitzroy (1737–1797), a grandson of Charles Fitzroy, 2nd duke of Grafton, he being thus, like the holders of the dukedom of Southampton, descended from Charles II. and the duchess of Cleveland. The title is still held by his descendants.

SOUTHAMPTON, HENRY WRIOTHESLEY, 3RD EARL OF (1573–1624), one of Shakespeare's patrons, was the second son of Henry Wriothesley, 2nd earl of Southampton, and his wife Mary Browne, daughter of the 1st Viscount Montague. He was born at Cowdray House, near Midhurst, on the 6th of October 1573, and succeeded to the title in 1581, when he became a royal ward, under the immediate care of Lord Burghley. He entered St John's College, Cambridge, in 1585, graduating M.A. in 1589; and his name was entered at Gray's Inn before he left the university. At the age of seventeen he was presented at court, where he was soon counted among the friends of the earl of Essex, and was distinguished by extraordinary marks of the queen's favour. He became a munificent patron of poets. Nashe dedicated his romance of *Jack Wilton* to him, and Gervase Markham his poem on Sir Richard Grenville's last fight. His name is also associated with Barnabe Barnes's *Parthenophil and Parthenope*, and with the *Worlde of Wordes* of John Florio, who was for some years in his personal service as teacher of Italian. But it is as a patron of the drama and especially of Shakespeare that he is best known. "My Lord Southampton and Lord Rutland,"[1] writes Rowland White to Sir Robert Sydney in 1599, "come not to the court . . . They pass away the time in London merely in going to plays every day" (*Sydney Papers*, ed. Collins, ii. 132). *Venus and Adonis* (1593) is dedicated to Southampton in terms expressing respect, but no special intimacy; but in the dedication of *Lucrece* (1594) the tone is very different. "The love I dedicate to your lordship is without end . . . What I have done is yours; what I have to do is yours; being part in all I have, devoted yours." Nicholas Rowe, on the authority of Sir William Davenant, stated in his *Life of Shakespeare* that Southampton on one occasion gave Shakespeare a present of £1000 to complete a purchase.

Nathan Drake in his *Shakespeare and his Times* (1819; vol. ii. pp. 62 seq.) first suggested that Lord Southampton was the person to whom the sonnets of Shakespeare were addressed. He set aside Thomas Thorpe's dedication to the "onlie begetter" of the sonnets, "Mr W. H.," by adopting the very unusual significance given by George Chalmers to the word "begetter," which he takes as equivalent to "procurer." "Mr W. H." was thus to be considered only as the bookseller who obtained the MS. Other adherents of the Southampton theory suggest that the initials H. W. (Henry Wriothesley) were simply reversed for the sake of concealment by the publisher. It is possible in any case that too much stress has been laid on Thomas Thorpe's mystification. The chief arguments in favour of the Southampton theory are the agreement of the sonnets with the tone of the dedication of *Lucrece*, the friendly relations known to have existed between Southampton and the poet, and the correspondence, at best slight, between the energetic character of the earl and that of the young man of the sonnets. Mr Arthur Acheson (*Shakespeare and the Rival Poet*, 1903) brings much evidence in favour of the theory, first propounded by William Minto, that George Chapman, whose style is parodied by Shakespeare in the 21st sonnet and in *Love's Labour's Lost*, was the rival poet of the 78th and following sonnets. Mr Acheson goes on to suppose that Chapman's erotic poems were written with a view to gaining Southampton's patronage, and that that nobleman had refused the dedication as the result of Shakespeare's expostulations. The obscurity surrounding the subject is hardly lightened by the dialogue between H. W. and W. S. in *Willobie his Avisa*, a poem printed in 1549 as the work of Henry Willobie (*q.v.*) If the sonnets were indeed addressed to Southampton, the earlier ones urging marriage upon him must have been written before the beginning (1595) of his intrigue with Elizabeth Vernon, cousin of the Earl of Essex, which ended in 1598 with a hasty marriage that brought down Queen Elizabeth's anger on both the contracting parties, who spent some time in the Fleet prison in consequence. The "Southampton" theory of the sonnets cannot be regarded as proved, and must in any case be considered in relation to other interpretations (see SHAKESPEARE).

Meanwhile in 1596 and 1597 Southampton had been actively employed, having accompanied Essex on his two expeditions to Cadiz and to the Azores, in the latter of which he distinguished himself by his daring tactics. In 1598 he had a brawl at court with Ambrose Willoughby, and later in the same year he attended Sir Robert Cecil on an embassy to Paris. In 1599 he went to Ireland with Essex, who made him general of his horse, but the queen insisted that the appointment should be cancelled, and Southampton returned to London. He was deeply involved in Essex's conspiracy against the queen, and in February 1601 was sentenced to death. Sir Robert Cecil obtained the commutation of the penalty to imprisonment for life.

On the accession of James I. Southampton resumed his place at court and received numerous honours from the new king. On the eve of the abortive rebellion of Essex he had induced the players at the Globe theatre to revive *Richard II.*, and on his release from prison in 1603 he resumed his connexion with the stage. In 1603 he entertained Queen Anne with a performance

[1] Roger Manners, 5th earl of Rutland, a close ally and friend of Southampton.

of *Love's Labour's Lost* by Burbage and his company, to which Shakespeare belonged, at Southampton House.

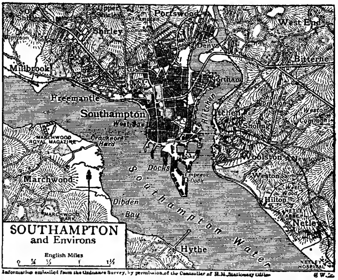
Southampton took a considerable share in promoting the colonial enterprises of the time, and was an active member of the Virginia company's council. He seems to have been a born fighter, and engaged in more than one serious quarrel at court, being imprisoned for a short time in 1603. He was in more serious disgrace in 1621 for his determined opposition to Buckingham. He was a volunteer on the Protestant side in Germany in 1614, and in 1617 he proposed to fit out an expedition against the Barbary pirates. In 1624 he and his elder son enrolled themselves as volunteers for the United Provinces of the Netherlands against Spain. Immediately on landing they were attacked with fever, to which both succumbed, the father surviving until the 10th of November 1624.

There exist numerous portraits of Southampton, in which he is depicted with dark auburn hair and blue eyes, compatible with Shakespeare's description of a "man right fair." Sir John Beaumont (1583–1627) wrote a well-known elegy in his praise, and Gervase Markham wrote of him in a tract entitled *Honour in his Perfection, or a Treatise in Commendation of . . . Henry, Earl of Oxenford, Henry, Earle of Southampton, Robert, Earl of Essex* (1624).

For further information see "Memoirs of Henry Wriothesley, the third Earl of Southampton," in Boswell's *Shakespeare* (1821), xx. 427 sqq., where many of the elegies on Southampton are printed; also Nathan Drake, *Shakespeare and his Times* (1817), ii. 1–20; Sidney Lee, *Life of William Shakespeare* (1898); Gerald Massey, *The Secret Drama of Shakespeare's Sonnets* (1888); Samuel Butler, *Shakespeare's Sonnets Reconsidered* (1899), where there is some distinctive criticism of the Southampton theory (ch. v.–vii.); an article by William Archer, "Shakespeare's Sonnets. The Case against Southampton," in the *Fortnightly Review* (Dec. 1897); and Sidney Lee's article on Southampton in the *Dict. Nat. Biog.*, arguing in favour of his identity with the hero of the sonnets. P. Alvor in *Das neue Shakespeare Evangelium* (Munich, 1906), brings forward a theory that Southampton and Rutland were the authors of the Shakespeare tragedies and comedies respectively, and borrowed William Shakespeare's name to secure themselves from Elizabeth's suspicion.

SOUTHAMPTON, a municipal, county, and parliamentary borough of Hampshire, England, a seaport, and county in itself, 79 m. S.W. by S. from London by the London & South-Western railway. Pop. (1901), 104,824. It is finely situated near the head of Southampton Water, an inlet of the English Channel which forms the estuary of the river Test; on a peninsula bounded east by the river Itchen. There are considerable remains of the old town walls, dating from Norman times, but strengthened on various later occasions. The most remarkable portion occurs on the western side, where for a distance of nearly 100 yds. the wall is arcaded on its exterior face. The wall was strengthened by towers at intervals, such as the Arundel Tower at the north-western corner. The site of the castle, on the western side near the water, is built over, but the wall is well seen here. The castle was originally a Saxon fortress, and was rebuilt on the erection of the walls. It was partly demolished in 1650, and in 1805 its reconstruction was begun by the marquess of Lansdowne, but was not completed. Near the site there are some very ancient houses, one of which, known as King John's Palace, is of the highest interest, as it is considered to be earlier than any example of the 12th century in England, and is well preserved. Of the ancient town gates the Bar or North Gate, South Gate, West Gate, and Blue Anchor Gate remain. The first three are important; the South and West gates date from the early 14th century, while Bar Gate, as it stands, is later, and retains excellent Decorated work. Numerous early vaults remain below the houses within the walls. The two old churches, St Michael's, the central tower and lofty spire of which rise from Norman arches, and Holy Rood, partly Decorated, are greatly modernized. St Michael's contains a Norman font of black marble, comparable with that in Winchester Cathedral. All Saints' Church dates from 1795, and among numerous modern churches St Mary's, erected from designs by G. E. Street, is noteworthy, and occupies the site of a Saxon church. The chapel of St Julian, where French Anglican services are held, is of transitional Norman architecture, greatly altered by restoration. It was originally attached to the hospital of God's House, founded in the time of Henry III. for eight poor persons, the existing buildings of which are modern. In the chapel are buried the earl of Cambridge, Lord Scrope, and Sir Thomas Grey, who were executed in 1415 outside the Bar Gate for conspiracy against Henry V. The chapel was allocated as a place of worship by Queen Elizabeth to certain Protestant Walloon refugees. The priory of St Denys, an Augustinian foundation of 1124, gives name to a suburb by the Itchen, and has left only fragmentary ruins.

In the municipal offices interesting ancient regalia and records are kept. The Gildhall, used as a court-house, is in the upper part of Bar Gate. Noteworthy modern buildings are the public library, corn exchange, custom-house, and assembly rooms. The Hartley Institution, founded under the will of Mr H. R. Hartley, contains a library, museum, art gallery, lecture hall, laboratories, and school of science and art associated with that of South Kensington, London; the foundation was created for



Information embodied from the Ordnance Survey, by permission of the Controller of H.M. Stationery Office

the advancement of natural history, astronomy, antiquities, and classical and Oriental literature. The Edward VI. grammar school was founded in 1550 and reorganized in 1875, and occupies modern buildings. Alderman Taunton's trade school was founded in 1752, and includes a technical department. The ordnance survey office is the headquarters of the ordnance survey department of Great Britain and Ireland. The Royal South Hampshire Infirmary is the principal of numerous benevolent and charitable institutions. To the north of the old town are the East and West Parks and the Hampshire county cricket ground, and to the south the small Queen's Park. Southampton Common, with its fine avenue, north of the town, was formerly part of the manor of Shirley. There is a statue in the parks of Dr Isaac Watts, the theologian (1674–1748), a native of the town, in whose memory the Watts Memorial Hall was erected in 1875. The headquarters of the Royal Southampton and the Royal Southern Yacht Clubs are in the town.

The history of the modern importance of Southampton as a port begins with the creation of a pier and harbour commission in 1803, and the erection of the Royal Victoria Pier (opened by Princess, afterwards Queen, Victoria) in 1831. But its present prosperity really dates from the opening of railway communication with London in 1840. The harbour is one of the finest natural harbours in the kingdom, and has the advantage of a double tide, the tide of the English channel giving it high water first by way of the Solent and two hours later by way of Spithead. In 1892 the docks, which lie at the southern end of the peninsula, became the property of the London & South-Western Railway Company. They measure about 300 acres, comprising extensive quays in both the Test and the Itchen rivers, with 28 ft. and upwards of water at low water of ordinary spring tides, and over 15,000 lineal feet of accommodation; the Empress dock, $18\frac{1}{2}$ acres, with a depth of 26 ft. at low water spring tide; the outer dock, 16 acres, with 18 ft. at low water spring tide; and the inner dock, 10 acres. In 1907 the construction of a new dock was undertaken, to cover 16 acres, with a depth of 40 ft. below low water. There are also two coal barge docks capable of floating 10,000 tons of coal at one time. There are five dry docks, having from 29 ft. to 12 ft. depth of water over blocks at neaps. The Prince of Wales, or No. 5 dry dock, opened in 1895, was at that time the largest single dock in the world; it is 750 ft. long by $87\frac{1}{2}$ ft. wide at sill, and 112 ft. at cope level. In 1905 a sixth graving dock was opened, having a length of $875\frac{1}{4}$ ft., and a width of 90 ft. at sill and 125 ft. at cope level. The principal passenger steamers sailing from the port are those of the Royal Mail Steam Packet Company for the West Indies and the Pacific (via Panama) and for Brazil and the River Plate, &c., and the Union-Castle line for the Cape of Good Hope, Natal, East Africa, &c., both of which companies have their headquarters here. New York is served by the American line, the North German Lloyd line, &c. Regular steamers serve the Channel Islands, Cherbourg and Havre, the principal English ports, Dublin, Belfast and Glasgow; and local steamers serve Cowes (Isle of Wight) and other neighbouring ports. The South-Western Company owns the local railway stations (Town and Dock and Southampton West, besides suburban stations), but through connexions are made with the north by way of the Great Western and Great Central and the Midland and South-Western Junction railways. Among the principal imports are cocoa, coffee, grain (including Indian corn), fruit, provisions (including butter, eggs and potatoes from France and the Channel Islands), wines and spirits, sugar, wool, and other foreign and colonial produce. Exports are all kinds of manufactured goods, such as cotton, linen, woollen, worsted and leather goods, machinery and hardware.

Southampton gives name to a suffragan bishopric in the diocese of Winchester. The parliamentary borough returns two members. The county borough was created in 1888. The town is governed by a mayor, sheriff, senior and junior bailiffs, 13 aldermen, and 39 councillors. The area, which includes the suburbs of Shirley, Freemantle and others, is 4501 acres.

History.—There was a Roman settlement of some importance on the site of the suburb of Bitterne on the E. bank of the Itchen. It was walled, and inscribed stones, coins, pottery, &c., have been found. It is probable that after the Danish invasions of the 11th century the modern Southampton (*Hantune*, *Suhampton*) gradually superseded the Saxon *Hantune* as the latter did the Roman settlement, the site being chosen for its stronger position and greater facilities for trade. It was a royal borough before 1086, and a charter of Henry II. (1154–5) declares that the men of Southampton shall hold their gild liberties and customs as in the time of Henry I. Richard I. in 1189 freed the burgesses from tolls and all secular customs. In 1199 John repeated the grant and gave them the farm of the customs of their own port and those of Portsmouth at a yearly rent of £200. Henry III. in 1256 granted all the liberties and customs enjoyed by Winchester. Grants and confirmations were made from the reign of Henry III. to Henry VI., that of 1401 (2 Henry IV.) granting further to the mayor and bailiffs cognisance of all pleas to be held in the Gildhall (*guyhalda*). The charter of incorporation was given by Henry VI. in 1445, under which the town was governed by a mayor, 2 bailiffs and burgesses, while by charter of 1447 the neighbouring district was amalgamated with the new borough as a distinct county under the title of "the town and county of the town of Southampton." Further privileges were granted by successive kings, and a charter was finally given by Charles I. in 1640. Southampton has returned two members to parliament since 1295. The inhabitants appear to have had a prescriptive right to hold a cattle-market, which was confirmed by Henry IV. in 1400, and later by Elizabeth. Markets on Wednesday for cattle and Friday for corn are now held. Trinity fair, dating from the year 1443, is now a pleasure fair. In medieval times Southampton owed its importance to the fact that it was the chief port of Winchester. It had a large import and export trade, and in the 13th century was the second wine port in England. Wool was very largely exported, and the fact that it was brought to this port to be shipped probably led to the first establishment of the woollen trade in the W. of England. The rise of London as a port, the prohibition of the export of wool, the loss of the Winchester market after the suppression of the monastic institutions, and the withdrawal of the court led to the gradual decline of trade from the 16th century onwards until railway facilities and the opening of new dockyards gave Southampton the position it holds to-day.

See *Victoria County History: Hampshire*, iii. 490 seq.; B. B. Woodward, *History of Hampshire* (London, 1861–9); Rev. Silvester Davies, *History of Southampton* (London, 1883).

SOUTHAMPTON, a township of Suffolk county, New York, occupying the western part (W. of Easthampton) of the south-eastern peninsula of Long Island, S. of the Peconic Bay and N. of the Atlantic Ocean. Pop. (1900), 10,371; (1910), 11,240. Separated from the ocean by a narrow beach only, in the south-western part of the township are the nearly landlocked East Bay and Shinnecock Bay, and farther east are Mecox Bay (landlocked) and other ponds near the ocean. At Canoe Place, an old portage, Shinnecock Bay and Peconic Bay are less than 3 m. apart. On the northern shore of the township are the small settlements called Flanders, Southport, Sebonac, North Haven and North Sea. Nearer the south shore and served by the Long Island railway are Speonk, Westhampton, Quogue, Good Ground, Shinnecock Hills, Southampton (pop. in 1910, 2509), Water Mill and Bridgehampton, from which there is a branch line of the Long Island railway to Sag Harbor. Good sailing and sea-bathing are obtained at several places; and the golf links of the Shinnecock Golf Club, at Shinnecock Hills, is one of the best in the country. The first "summer cottages" were built near the village of Southampton in the latter part of the decade 1870–1880, and the summer colony was long called the "New York Annex" or the "Annex." The village of Southampton has been called the Newport of Long Island; in it is the Rogers Memorial Library (1893). The whale fishery was formerly important; it began here about 1660. The Shinnecock Indians long took part in it and many of the men of the tribe were lost in the wreck of the "Circassian" here on the 31st of December 1876. The Indians now on the reservation are mostly mixed bloods with a large proportion of negro blood. Southampton was settled in 1640, probably before Southold, by a "company of undertakers" formed in March 1639 at Lynn, Massachusetts, who received from James Forrett, agent of the proprietor, William Alexander, Lord Stirling, a patent dated the 17th of April 1640 for 8 m. square of land and whose deed from the Indians is dated the 13th of December 1640. Their first attempt to settle was broken up by the Dutch. The name may have been taken in honour of Henry Wriothesley, earl of Southampton. The settlement was a commercial scheme, and in spite of the rigid Puritanism of Abraham Pierson, their first pastor and a sympathizer with New Haven, the people voted to attach themselves to Connecticut (1645). The Mosaic law was adopted for the government of the township. In 1678 Governor Edmund Andros, in a note to the home government, said: "Our principall places of trade are New York and Southampton, except Albany for the Indyans." The village of Southampton was incorporated in 1894.

See Geo. R. Howell, *Early History of Southampton, L.I.* (2nd ed., Albany, 1887), and the *Town Records* (4 vols., Sag Harbor, 1874–1879), with notes by W. S. Pelletreau.

SOUTH AUSTRALIA, a British colonial state, forming part of the Commonwealth of Australia. (For map, see AUSTRALIA). It lies between 129° and 141° E. long., has Queensland, New South Wales and Victoria on the E., Western Australia on the W., and the Southern Ocean on the S. Originally its northern line was 26° S. lat.; by the addition of the Northern Territory the area was extended from 380,070 sq. m. to 903,690, and the northern border carried to the Indian Ocean;

but by acts of 1910 this territory was made over to the federal government. It is, however, described below.

The southern coast-line shows two large gulfs, Spencer and St Vincent—the first 180 m. long, the other 100. Spencer Gulf is open to the ocean, while St Vincent Gulf is partly shielded by Kangaroo Island, with Investigator Straits as its western and Backstairs Passage as its eastern entrance. Yorke Peninsula separates the two gulfs. Eyre's Peninsula is to the west of Spencer Gulf, and at its southern extremity are Port Lincoln, Sleaford Bay and Coffin's Bay, of which the first is the most important. Along the Great Australian Bight are several small bays, and the junction of South and Western Australia is on the Bight. Going eastward from the Gulf of St Vincent is Encounter Bay, through which there is an entrance to Lake Alexandrina, the mouth of the Murray river. The Coorong is the name given to the narrow sheet of water, nearly 200 m. long, formed by the Murray and separated from the ocean by a very narrow strip of land. Lacepede and Rivoli Bays are the only other important indentations of this coast. In Northern Territory are several important indentations, Melville, Adam, Arnheim and Raffles Bays, Van Diemen's Gulf, Port Essington and Port Darwin (lat. 12° S.). The Gulf of Carpentaria divides the territory from Cape Yorke Peninsula of Queensland, the more important inlets on the shore of the gulf in Northern Territory being Caledon Bay and Limmen Bight. The principal island belonging to South Australia is Kangaroo Island, situated at the mouth of the Gulf of St Vincent; it is also the longest Australian island, measuring 210 m. by 85 m. at its widest part. Off the north coast of Northern Territory are Melville and Bathurst Islands, the Wessel group, and Groote Eylandt in the Gulf of Carpentaria.

Mountain ranges are not an important feature of the country, which, on the whole, is level where not slightly undulating. In the south of the state the principal ranges run north and south; the Mount Lofty range, beginning at Cape Jervis, runs parallel with St Vincent's Gulf and at one or two points touches 3000 ft., Mount Lofty, near Adelaide, having an elevation of 2330 ft. The Flinders range rises on the eastern shores of Spencer Gulf and extends north for several hundred miles, terminating near the so-called Lake Blanche; there are in this range several isolated peaks which attain 3000 ft., the most prominent being Mt Remarkable, 3100 ft., Mt Brown, about the same height, and Mts Arden and Serle, about 3000 ft. The Gawler range, running across Eyre's Peninsula, south of the lakes, attains an elevation of about 2000 ft. at several points. Beyond Lake Torrens the ranges tend in the direction of north-west and afterwards east and westerly; and occasional summits reach 5000 ft. Northern Territory is traversed by several minor ranges, but the country has not been thoroughly explored and the heights and direction of the ranges have not been in all cases determined; no elevation above 2000 ft. has, however, been discovered.

South Australia is by no means a well-watered country, but there are some fine streams in the north of Northern Territory. In South Australia proper the Murray enters the sea at Lake Alexandrina, after having received the drainage of three states. The Torrens, Wakefield, Hindmarsh, Tuman and Gawler are unimportant streams; on the banks of the first named is situated the city of Adelaide. From Queensland flows the Barcoo, or Cooper's Creek, into Lake Eyre, which also receives the Macumba, with its tributary the Alberga, and several other rivers. These are rivers only when they are filled with the torrential rains of the interior, and for the most part are depressions destitute of water. Northern Territory is marked by an absence of water except at the extreme north, where there are several fine rivers, some of which are navigable for over 100 m.; the most noteworthy are: the Roper, flowing into Limmen Bight in the Gulf of Carpentaria, the Liverpool, the South Alligator, the Adelaide, the Daly and the Victoria. There are numerous lakes shown on the maps of South Australia, but none are permanent; they are depressions filled by the rivers in times of flood, but otherwise waterless or containing shallow pools of salt water. (T. A. C.)

Geology.—South Australia may be divided geologically into four parts, the geology of each of which is so distinct that they may be conveniently considered apart. These divisions are (1) the Great Valley of South Australia and the adjacent highlands that border it, (2) the Lake Eyre Basin, (3) the Western Plateau, (4) the basin of the Lower Murray, with (5) the Northern Territory.

The western division consists of a plateau of Archean gneisses, granites and schists, which extend across Australia from the Eyre Peninsula on the south to the northern coasts on Port Darwin. In the south-western corner of the state the Archean plateau is separated from the Southern Ocean by the Cainozoic limestones of the Nullarbor plains, which extend from the shore of the Great Australian Bight to the foot of the great Victorian desert. Thence northward, the Archean rocks form the whole foundation of the country, until they end in a scarp, the "so-called coastal range," to the south of the Gulf of Carpentaria, and in the exposures near Palmerston, on Port Darwin. This plateau bears occasional deposits of later age. The chief of these are the Ordovician rocks of the Macdonnell Chain; they there trend approximately west-north-west to east-south-east, and represent part of the old Lower Palaeozoic mountain chain, which appears to have once extended across Australia from Kimberley to Adelaide and Tasmania. To the north-east of the Ordovician rocks of the Macdonnell Chain are the Cambrian deposits of Tempe Downs and the head of the Herbert river. Some Jurassic fresh-water deposits occur in basins on the plateau, having been proved by a bore, now being put down, in the hope of forming a flowing well at Lake Phillipson.

In contrast to the striking uniformity of the Western Plateau is the geological complexity of the part of South Australia known as "the Counties," including the settled districts in the south of the state around Spencer Gulf. The country is underlain by Archean and granitic rocks; they are exposed in the Gawler Range to the west, in the Archean outcrops near the New South Wales frontier, on the railway to Broken Hill, and at the foot of the highlands, along the western edge of the Murray basin. The highlands of South Australia consist mainly of contorted Lower Palaeozoic rocks, including the best representative in Australia of the Cambrian system. These Cambrian deposits, in addition to yielding a rich Cambrian fauna, contain a long belt of glacial deposits, the discovery of which is due to W. Howchin. These highlands form the whole of the mountainous country to the east of Lake Torrens; they extend southward to the highlands behind Adelaide, and form the axis of Kangaroo Island, while a branch from them forms the backbone of Yorke Peninsula. The highlands end to the north along a line running approximately east and west through Mt Babbage and the Willouran and Hergott ranges, to the south of Lake Eyre. The country to the west of Lake Torrens is a plateau, capped by the Lake Torrens Quartzites, which are apparently of Upper Palaeozoic age. This plateau has been separated from the South Australian highlands by the formation of the rift valley, in which lie Lake Torrens and Spencer Gulf. St Vincent Gulf occupies a foundered area between the Mount Lofty ranges, the Yorke Peninsula and Kangaroo Island. The south-eastern corner of South Australia is occupied by the basin of the Lower Murray, which in middle Cainozoic times was occupied by a sea, in which was laid down a thick series of marine sands and limestones. These rocks have yielded a rich fossil fauna from the cliffs beside the Murray. In the southern part of this district there is a western continuation of the basaltic sheets so conspicuous in Victoria. Some of them have been ejected from volcanoes, of which the vents are still well marked. The best extinct crater known is Mt Gambier.

The Lake Eyre basin occupies a vast depression to the north of the South Australian highlands; it is bounded to the west by a line of ridges and mountains of Archean and Lower Palaeozoic rocks, which connect the north-western end of the South Australian highlands with the mountains on the Archean plateau at the head of the Macumba and the Finke rivers. The Lake Eyre basin was occupied in Lower Cretaceous times by a sea, which extended southward from the Gulf of Carpentaria; and it appears to have been bounded to the south by the northern edge of the South Australian highlands. In this sea were laid down sheets of clays, known as the Rolling Downs formation. After the retreat of this sea the clays were covered by the Desert Sandstone, which has been cut up by denudation into isolated plateaux and tent-shaped hills. On the margin of the Desert Sandstone in Queensland there are some marine beds interstratified with the Desert Sandstone, and the fossils fix its age as Upper Cretaceous. The origin of the Desert Sandstone has given rise to considerable discussion; but it is no doubt in the main a terrestrial formation including some lake deposits. The surface is often converted into a vitreous quartzite by deposition of an efflorescent chert. Obsidian buttons are scattered over the central deserts, and have been regarded as of meteoric origin; they have also been considered proof of local volcanic action, but they have probably been scattered by the aborigines. Extensive estuarine deposits of Pliocene or early Pleistocene age, with a rich fauna of extinct marsupials and birds, occur on the plains to the east of Lake Eyre.

The Northern Territory includes the mountains of the Macdonnell Chain, and all the country thence to the northern coast. It consists of an Archean plateau, covered in places by Cambrian and Ordovician deposits. To the north of the Victoria river and the Roper

River, the country rises into a high, dissected table-land of Archean rocks; but round the coast there is a coastal plain including Permo-Carboniferous, Cretaceous and Cainozoic deposits. The Cretaceous deposits include ammonites of the *varians* type and a species of *Aucella*.

The chief mineral product of South Australia is copper, the mines of which occur in Cambrian limestones along the western edge of the South Australian highlands at Moonta, Wallaroo and Burra Burra. Gold occurs in numerous small mines in the South Australian highlands; and also in the Western Plateau, as in the Tarcoola goldfield; and in the Northern Territory, in the Arltunga goldfield, at the eastern end of the Macdonnell chain. Gold and tin are scattered in the Arnheim Peninsula of the Northern Territory; but hitherto the gold-mines of South Australia have been less important than those of any other of the Australian states. The only coal deposits are those formed in lacustrine deposits of Jurassic age, as at Leigh's Creek, east of Lake Torrens, where they have been mined.

Most of the geological information regarding South Australia is scattered in a series of reports, mainly by H. Y. L. Brown, published in the parliamentary papers of South Australia. There are also numerous reports by R. Tate, W. Howchin, &c. in the *Trans. R. Soc. S. Austral.* The geology of the Macdonnell range is described in the reports of the Horn Expedition, and the fauna of Lake Callabonna in *Memoirs* issued by Stirling and Zeitz, published by the Royal Society of South Australia. The literature is catalogued in Gill's *Bibliography of South Australia* (Adelaide, 1885), and that of the Lake Eyre basin and its adjacent islands in J. W. Gregory, *The Dead Heart of Australia* (1906). The Miocene marine fauna has been catalogued last by Dennant and Kitson, *Records Geol. Survey, Victoria* (1905), No. II. (J. W. G.)

Fauna.—South Australia is not separated from the neighbouring colonies by any natural boundaries; hence the fauna includes many animals which are also to be found in the land lying to the east and west. The northern half of the colony lies within the tropics, and possesses a tropical fauna, which is, however, practically identical with that of Northern Queensland. In spite of its immense extent north and south, and a corresponding diversity in climate, the colony is poorer in animal life than its neighbours. It possesses thirty-five genera of mammals. These include both genera of the order *Monotremata*—the *Echidna*, or spiny ant-eater, and the *Ornithorhynchus*, or duck-billed platypus, both of which are found also in Eastern Australia and Tasmania. The other order of *Mammalia* associated with Australia, the *Marsupialia*, is well represented in South Australia. It contains seven genera of *Macropodidae* or kangaroos, including the wallaby and kangaroo rat, four genera of *Phalangistidae*, or opossums, and five species of *Dasyuridae*, or "native cats." Two genera of this family are peculiar to the region—the *Chaetocercus* and the *Antichinomys*; the latter is found in the interior. It is a mouse-like animal with large ears, and is remarkable for the elongation of its fore-arm and hind-foot and for the complete absence of the hallux. The *Phascolomys*, or wombat, one of the largest of the marsupials, is also found in South Australia, and the curious *Myrmecobius*, or ant-eater of Western Australia. This remarkable animal is about the size of a squirrel; it possesses fifty-two teeth (a greater number than any known quadruped), and, unlike the other members of its order, the female has no pouch, the young hanging from nipples concealed amongst the hair of her abdomen. The *Choeropus*, with peculiarly slender limbs and a pouch opening backwards, is found in the interior. The remaining *Mammalia* consist of the dingo, or native dog, and a few species of *Muridae*, the mouse family, and *Cheiroptera*, or bats. There are about 700 species of birds, including 60 species of parrots. Of the 9 families peculiar to the Australian region, 5 are well represented, including the *Meliphagidae* (honey-suckers), *Cacatuidae* (cockatoos), *Platycercidae* (broad-tailed and grass parakeets), *Megapodidae* (mound-makers) and *Casuaridae* (cassowaries). The last-named family is represented by the *Dromaeus*, or emu, which is hunted in some parts of the colony. Reptiles are fairly represented: there are fifteen species of poisonous snakes. The lizards are very peculiar; South and Western Australia contain twelve peculiar genera. No tailed *Amphibia* exist in the continent, but frogs and toads are plentiful.

Flora.—The plant species resemble those of the eastern colonies and Western Australia, but are more limited in variety. The colony, from its dryness, lacks a number known elsewhere. Enormous areas are almost destitute of forests or of timber trees. The *Eucalyptus* family, so valuable for timber and gum as well as for sanitary reasons, are fairly represented. Acacias are abundant, the bark of some being an article of commerce. Flinders range has much of the valuable sugar-gum, *Eucalyptus Corynocalyx*, which is being now preserved in forest reserves. Its timber is very hard and strong, not warping, resisting damp and ants. The head-flowered stringybark, *Euc. capitellata*, has a persistent bark. A sort of stringybark, *Euc. tetrodonta*, is found in Northern Territory. The gouty-stem tree (*Adansonia*) or monkey-bread of the north is a sort of baobab. About 500 northern plants are Indian. The *Tamarindus indica* occurs in Arnhem land, with native rice, rattans and wild nutmeg. The cedar is of the Indian variety. Pines are numerous in the south, palms in the north; among the most beautiful is the *Kentia acuminata*. Banksias are very common in sandy districts. Flowering shrubs are common in the south. There are 130 known grasses in Northern Territory.

Fisheries.—Whaling was formerly an important industry about Encounter Bay, as sealing was in Kangaroo Island. The whales have migrated and the seals are exterminated. On the northern side trepang or bêche-de-mer fishery is carried on, and pearl fisheries have been established. Of fish within colonial waters there are forty-two peculiar genera. The tropical north has similar fish to those of north Queensland, while those of southern bays resemble many of the species of Victoria, Tasmania and New South Wales. There are the barracouta, bonito, bream, carp, catfish, rock cod and Murray cod, conger, crayfish, cuttle, dogfish, eel, flatfish, flathead, flounder, flying-fish, gadfish, grayling, gurnard, hake, John Dory, ray, salmon (so-called), schnapper, seahorse, shark, sole, squid, swordfish, whiting, &c. Though called by English names, the fish do not always correspond to those in Europe. The Murray cod is a noble fresh-water fish.

Climate.—The climate of South Australia proper is, on the whole, extremely healthy, and in many respects resembles that of southern Europe. In the south-eastern corner of the state the spring and winter seasons are most pleasant, and although the thermometer occasionally registers high in summer, the heat is dry and much more endurable than a much lesser heat in a moist climate. In the interior districts, however, the heat is sometimes very trying to Europeans. In Northern Territory the climate is of a tropical character, except on the table-lands where it is comparatively cool. Observation has determined the area of the state adapted by reason of seasonal rains to the growth of wheat, and in this area crops are almost certain; agriculture outside this area is, however, purely speculative. The average rainfall at Adelaide taken for a period of 52 years was 21·204 in. As the rain falls at seasonable times the quantity is sufficient for cereal cultivation. The maximum shade temperature recorded at Adelaide Observatory in 1905 was 109·7—the highest for any Australian city; the minimum was 34·8 and the mean temperature 61·1.

Population.—The population of South Australia in 1860 was 124,112, and the province was third in importance among the states forming the Australasian group. In 1870 the population stood at 183,797, and in 1880 at 267,573; in 1890 it was 319,414; in 1901, 362,604; and at the end of 1905, 378,208. These figures are inclusive of the population of Northern Territory, the province of South Australia, properly so-called, containing 374,398 inhabitants, and Northern Territory, 3810, the respective density of the two divisions being one person per square mile and one per 128 sq. m. The estimated population of Adelaide in 1905 was 175,000. The number of males in 1905 was 197,487, and the females 180,721. The births in the same year were 8868 and the deaths 3804, representing 23·44 and 10·05 per 1000 of population respectively. The birth-rate has declined greatly.

Dividing the years from 1861 to 1905 into five-yearly groups the following were the average birth-rates:—

Period.	Births per 1000 of Population.	Period.	Births per 1000 of Population.
1861–1865	44·14	1886–1890	34·48
1866–1870	40·60	1891–1895	31·24
1871–1875	37·24	1896–1900	26·59
1876–1880	38·28	1900–1905	24·46
1881–1885	38·52		

Illegitimate births are less frequent in South Australia than elsewhere in Australia; in 1905 the proportion of illegitimate to total births was 4·37%.

The death-rate has always been remarkably light, not having exceeded 13 per 1000 in any year since 1886. The averages for each quinquennial period from 1861 were as follows:—

Period.	Deaths per 1000 of Population.	Period.	Deaths per 1000 of Population.
1861–1865	15·70	1886–1890	12·55
1866–1870	15·01	1891–1895	12·08
1871–1875	15·83	1896–1900	11·93
1876–1880	14·90	1901–1905	10·78
1881–1885	14·71		

The excess of births over deaths in 1905 was 5071 or 13·48 per 1000 of population. The number of marriages celebrated during 1905 was 2599; this represents a marriage-rate of 6·87 per 1000. The number of divorces and judicial separations during the ten years closing with 1905 was 72.

The people are mainly of British race; out of 362,604 persons whose birthplace was ascertained at the census of 1901, 348,352 were of British or Australian parentage, the number born in the Commonwealth being 289,440, and in South Australia itself 271,671; 9396 were born on the continent of Europe, of whom 6664 were Germans, and 931 Scandinavians and 3253 were Chinese. The total foreign-born element of the population numbered only 3·73%.

The census showed the number of breadwinners in the state to be 153,296—120,328 males and 32,968 females. Agriculture, the main industry, provided employment for 34,186 persons, of whom 33,039 were males and 1147 females. Pastoral pursuits employed 4193, dairying 2868 and mining 6301. The industrial class may be divided into (*a*) persons engaged in manufacturing industries, 18,163 males, 6761 females; (*b*) persons engaged in the construction of buildings, railways, roads, &c., numbering 8652; and (*c*) persons engaged in other industrial pursuits, 7657—these are chiefly persons whose census description is merely labourer. The commercial class, including trades of all kinds as well as persons engaged in finance, numbered 20,165, namely 17,080 males and 3085 females. The professional class comprised 5372 males and 3485 females, or a total of 8857; while the domestic class—comprising persons engaged in providing board and lodging, hotel and restaurant keepers, as well as servants—numbered 17,981, namely 3452 males and 14,529 females. The foregoing classes show the distribution of employment amongst the 153,296 breadwinners; the remainder of the population, comprising 209,308 persons (64,094 males and 145,214 females) were dependent on the breadwinners.

Administration.—South Australia, as one of the states of the Commonwealth, returns six senators and seven representatives to the Federal parliament. The local parliament consists of a Legislative Council and a House of Assembly. The former has eighteen members, elected by the districts into which the state is divided for that purpose, the franchise being limited to persons with freehold or leasehold estate, and to occupiers of dwellings of £25 annual value; while the Assembly contains 42 members, elected by 13 districts; the electoral qualifications for the Assembly are the attainment of the age of 21 years, and having been upon the electoral roll not less than six months. Women have the right to vote.

Local Government.—Adelaide was the first Australian city to acquire the right of self-government; on the 31st of October 1840 the first municipal elections in Australia were held in that city. There are 33 municipal councils and 142 district councils in the settled parts of the state, the area under local government being about 43,000 sq. m. Local rates are assessed upon the assumed annual value of the properties liable to be rated; and the amount of such assessed annual value was, in 1905, £2,739,808, and the capital value 55 millions. The revenue of the various local bodies in 1905 was £294,723, of which £170,235 was obtained from rates, £30,618 from government endowment and £93,870 from other sources; £130,489 was spent on public works. The total debt of the local bodies in that year was £102,261.

Education.—The South Australian system of popular education in its present form dates from 1878. It is compulsory, secular and free. The compulsory ages are over seven and under thirteen years, but children who have attained a certain standard of education are exempt from compulsory attendance. Religious instruction is not allowed to be given in state schools except out of ordinary school hours. Secondary instruction is in the hands of private and denominational establishments, and the university of Adelaide is well endowed and efficient. The state maintained in 1905 722 schools, with a gross enrolment of 59,026 pupils, and the average attendance was about 41,807. The sum expended in that year on public instruction was £181,583, and of that amount £150,000 was on account of primary instruction. Although education is free, the instruction department has a small revenue; this in 1905 amounted to £12,783. of which £6131 was derived from rents, £3630 from the sale of books and school material, and £682 from fees; the greater portion of the fees comes from the advanced school for girls, the remainder being paid by pupils attending classes in agriculture held in the public schools. The average cost of primary instruction to the state, including cost of school premises and maintenance, is about £3,11s. 4¼d. per scholar in average attendance. The revenue of the Adelaide University in 1905 was £21,462, 15s. 7d., of which £6639 was obtained from the government, £9845 from fees and £4979 from other sources. The number of students attending lectures during the same year was 595, of whom 366 had matriculated. Technical education is well advanced; the School of Mines and Industries, founded in 1899, had in 1905 an enrolment of 1600 students. Private schools numbered 213, with 725 teachers and 10,206 scholars. Of the teachers 559 were engaged in general instruction, while 166 were specially engaged in particular subjects.

The peculiarity of religion is the strength of the non-Episcopal churches. The Church of England, which includes over 40% of the population of the other Australian states, claims only 27% in South Australia; and the Roman Catholic Church, whose adherents number 22% in the other colonies, numbers about 14% in South Australia. The Presbyterian churches have also fewer supporters, for only 5·5% of the population belong to such churches, compared with 13% in the other colonies. To the Wesleyan churches 19% of the population belong, to the Congregational churches 3·7%, Baptists 5·5%, Lutherans 7·5%, and other Protestants about 8%.

Finance.—For the year ending June 1905 the state had a public revenue of £2,798,849, which is equal to £7, 10s. 2d. per inhabitant. This amount includes revenue received by the Commonwealth government on behalf of the state. The principal sources of public revenue were: customs duties (balance of amount collected by the Commonwealth government), £555,692; land, income and other taxes, £442,030; railways, £1,279,481; public lands, £192,337; other revenue, £527,843. In 1871 the revenue of the province was £778,000, or £4, 4s. 3d. per inhabitant; from that year it rose rapidly until in 1881 it stood at £2,172,000, or £7, 16s. 10d. per head; in 1891 it was £2,732,000, or £8, 11s. 1d. per head. The expenditure for the year ended the 30th of June 1905 was as follows: railway working expenses, £746,636; public instruction, £181,583; interest and charges of public debt, £1,049,643; other services, £915,261. The debt charges amount to £2, 11s. 8d. per head, and absorb 36·28% of the total revenue of the state. Against this must be placed the net return from services upon which the loan moneys were expended; this amounts to about £746,459, so that the real burden of the state's debt is reduced to £303,184 per annum. On the 30th of June 1905 the public debt of the state stood at £28,727,895, which is equal to £78, 1s. 1d. per head; and the purposes for which the debt was incurred were: railway construction and equipment, £13,732,567; water supply and sewerage, £4,993,638; telegraphs and telephones, £1,010,738; and other works and services not producing direct revenue, £8,990,952. These figures include the debt of the Northern Territory. The amount of the debt at certain periods beginning with 1861 was:—

Year.	Total Debt.	Debt per Head.
	£	£ s. d.
1861	866,500	6 16 8
1871	2,167,700	11 13 7
1881	11,196,800	39 2 1
1891	20,347,125	62 9 2
1901	26,423,805	73 2 6
1905	28,727,895	78 1 1

Defence.—As part of the Commonwealth the defence of South Australia is undertaken by the Federal government. On the 31st of December 1905 the defence force of the state totalled 5066 men, comprising 1262 partially paid troops, a paid staff of 37 and 3178 riflemen. In addition to the land force there is a corps of 127 men capable of being employed on local war vessels, or as a light artillery land force.

Minerals.—South Australia, though without coal, was the first Australian colony to have a metallic mine, and the first to possess a gold-mine. In 1841 the wheel of a dray, going over a hill near Adelaide, disclosed to view silver-lead ore. In the midst of the bad times in 1843 the Kapunda copper-mine was found. In 1845 the wonderful Burra Burra copper was first wrought. The land, 10,000 acres, cost £10,000; and for several years the dividends to shareholders were 800% per annum. The first colonial mineral export was 30 tons of lead ore, value £128, in 1843. The copper declined as prices fell. It was £322,983 in 1885, when rates were £50 a ton, but £762,386 ten years before with over £90. In 1886 most of the mines were closed. Between 250 and 400 m. north of Adelaide a very rich copper district exists. Lead is very abundant. Manganese, nickel, bismuth, antimony and silver have been mined. Tin is seen in granitic places. Iron occurs in almost all formations and in all conditions. There is abundance of haematite, micaceous, bog and other ores rich in the metal. Talisker and other mines paid in silver. The wonderful Silverton, of Barrier Ranges, in a desert, is just outside the boundary, though 300 m. only from Adelaide while 600 from Sydney. Gold was got from a quartz vein at the Victoria mine, near Adelaide, as early as 1846, but did not pay the company. Partial gold working has been conducted at Echunga, &c., in southern hills. There are rich alluvial and quartz gold mines in Northern Territory, at from 100 to 150 m. south of Port Darwin. For the year 1884 the yield was £77,935. Of 1349 miners 1205 were Chinese. Gold is now worked at Waukaringa, 225 m. north of Adelaide. Copper, tin and silver are found in Northern Territory. Among other minerals asbestos, roofing slates and fine marbles may be named. Some forty years ago precious stones, especially garnets and sapphires, were gathered in the Barossa Hills. Carbonaceous material is found at the Coorong, &c., yielding 50% of oil. Lake Eyre has a rude coal. Kapunda marble quarry is a success. The great copper mines at Moonta and

Wallaroo are still worked, but the production has greatly fallen off. In 1900 the value of copper raised in the province was £386,015, and the gross production to the end of that year amounted to £22,321,969. The production of copper in 1905 was £470,324. Gold to the value of £85,555 was won in 1905, being chiefly obtained in Northern Territory; the total production of gold prior to that year was £2,764,336. The value of minerals other than gold and copper won during 1905 was £96,672. In 1871 the mineral production of the state was valued at £725,000, in 1881 at £421,000, in 1891 at £365,000 and in 1905 at £652,551.

Land System.—The aggregate area of South Australia, exclusive of the Northern Territory, is computed to be 380,070 sq. m., or 243,244,800 acres. About 136,828 sq. m., or a little more than one-third, represent the limits within which the country is at present occupied. The 46 counties proclaimed to date embrace an area of 80,453 sq. m. or 51,489,920 acres, of which 7,955,305 acres are purchased, 365,526 acres are partly purchased and 121,735 acres have been granted for public purposes, making the total area alienated, wholly or conditionally, 8,442,566 acres; 176,537 acres are set apart, but not granted, for forest purposes, and 42,870,817 acres are still in possession of the Crown but occupied under various kinds of tenure, chiefly for pastoral purposes. In addition to the land alienated, there are 17,104,062 acres held direct from the Crown by 19,511 lessees for farming or grazing purposes. Outside the counties are 299,617 sq. m. or 191,754,880 acres, of which 1105 acres are purchased, 23 granted for public purposes, 76,570,750 held by 497 lessees as sheep or cattle runs, leaving 115,184,130 acres open for pastoral settlement, if suitable.

Agriculture.—South Australia is essentially an agricultural state. In its first establishment the land was cut up for sale into eighty-acre lots with the view of settling the people on arrival, and concentrating them, instead of having them scattered as in the neighbouring colonies, in which pastoral pursuits completely dwarfed the farming industry. This wise provision made the colony for years the supplier of breadstuffs to Sydney, Melbourne, Brisbane, Perth and Auckland. As neighbours became wheat-producers, Adelaide merchants had to seek markets in Natal, Mauritius, the Cape, or even Europe. At all times the state has lent every assistance to agriculture. As the colony suffers more from drought than anything else, public reservoirs are constructed and artesian wells are sunk. Forest culture has especially attracted government attention. Reforesting and the establishment of nurseries for the trees, fruits and vegetables of other lands go hand in hand. Hundreds of thousands of trees are planted annually.

The chief industry is wheat-growing; out of 3,342,626 acres under cultivation in 1905, 1,757,036 acres were under wheat for grain and 317,924 under wheat for hay. In some parts of South Australia fine yields are obtained; but taking it as a whole, the yield of the province is light. During the ten years 1891–1900 the return per acre varied from a minimum of 1·7 bushels in 1897 to a maximum of 6·1 bushels in 1893. South Australian wheat is of excellent quality and strength, and well known in European markets, to which the province has sent wheat since 1850. There has been little expansion of wheat cultivation since 1880; nor, indeed, has there been any material expansion in the total area under crop. Up to the year mentioned, every season showed an additional area devoted to cultivation; but repeated failure of crops, due to want of seasonable rain, have disheartened farmers, and much land that was formerly cultivated now lies fallow; 1,087,057 acres were fallow in 1905. The following is a statement of the area of wheat harvested for grain at specified intervals from 1861:—

Year.	Acreage under Wheat.	Production.	Average Yield per Acre.
	Acres.	Bushels.	Bushels.
1861	310,636	3,410,756	11·0
1871	692,508	3,967,079	5·7
1881	1,768,781	8,087,032	4·6
1891	1,552,423	6,436,488	5·6
1899	1,778,770	8,778,900	4·9
1900	1,821,137	8,453,135	4·6
1901	1,913,247	11,253,148	5·9
1905	1,757,036	20,143,798	11·46

The total area under crop during the same period was: 1861, 400,717 acres; 1871, 837,730 acres; 1881, 2,156,407 acres; 1891, 1,927,689 acres; 1901, 2,369,680 acres. In 1905 other leading crops grown with this acreage were: oats, 56,950 acres; barley, 26,250 acres; potatoes, 9540 acres; vines, 23,603 acres; other crops, 30,532 acres.

In viticulture the province has made considerable progress, and many Germans are employed in the industry. The production of wine for the year 1905 amounted to 2,845,853 gallons, while 16,714 cwt. of currants and 8697 cwt. of raisins were also made. The wine made is of excellent quality, and 718,660 gallons, of a total production of 2,845,853 gallons, were exported in 1905, principally to London.

The production of wool has been one of the chief industries since the foundation of the state, but of late years it has been much affected by droughts and low prices, so that the export of locally-grown wool in 1901 was considerably less in quantity than in 1880, and little more than half as valuable. In 1861 the colony carried 3,038,000 sheep; in 1871, 4,412,000; in 1881, 6,811,000; in 1891, 7,745,000; in 1900, 5,283,247; and in 1905, 6,202,330. The quantity of wool exported in the year last named was equal to 45,214,766 lb, valued at £1,668,214. As a cattle-breeding country South Australia does not take a prominent place beside the three eastern states of Australia. The province depastured, in 1905, 647,631 cattle as against 520,379 in 1904, 347,666 being in Northern Territory. In 1891 the number was 677,000, and 1881, 315,000. It was between 1881 and 1891 that Northern Territory was stocked. The horses in South Australia number about 216,350; the number in 1881 was 159,678.

Although there are some 30,000 persons engaged in one form or other of manufacturing, only 18,664 are accounted for in the annual statistics of the state; these hands are employed in 1339 establishments. The horse-power employed in the manufactories is 11,756, the value of the plant being estimated at £1,730,000.

Commerce.—The tonnage of shipping entering the ports in 1905 was 2,625,997, which is equal to upwards of 6 tons per inhabitant, a very considerable ratio compared with most countries; but this tonnage is quite beyond the requirements of the province, whose trade represents only about 750,000 tons per annum, and is due to the fact that Adelaide is a place of call for all the great lines of steamships trading between Europe and Australia; but when every allowance is made, it will be found that Adelaide is a great shipping centre and the third port of Australasia. The tonnage entering at Adelaide during 1905 was 2,106,854; at Port Pirie, 226,903; at Wallaroo, 105,228; and at Port Darwin, 116,981. The value of the total imports was £8,439,609, and the total exports £9,490,667. The ports command the greater part of the trade of the Broken Hill and trans-Darling districts of New South Wales, and this trade is very valuable both to the merchants and the railways of the province. The trade at the periods specified was:—

Year.	Imports.	Exports.	Total Trade.	Exports of Domestic Produce.
	£	£	£	£
1861	1,976,018	2,032,311	4,008,329	1,838,639
1871	2,158,022	3,582,397	5,740,419	3,289,861
1881	5,320,549	4,508,754	9,829,303	3,755,781
1891	10,051,123	10,642,416	20,693,539	4,810,512
1899	6,884,358	8,388,396	15,272,754	3,945,045
1900	8,131,782	8,122,100	16,253,882	3,770,983
1905	8,439,609	9,490,667	17,930,276	6,031,619

The great expansion following 1881 was due to the opening up of trade with the western districts of New South Wales. The exports of domestic produce, the value of which is given in the last column, when compared with the other figures in the table, show how greatly the province depends upon its re-export trade. The chief items of trade are breadstuffs, wool and minerals; the export of breadstuffs is very variable, depending so largely upon the rainfall, which in South Australia is extremely uncertain. In 1884 the value of wheat and flour exported was £2,491,896, falling to £633,426 in 1886, and rising again to £2,197,735 in 1888. Since the year last named there have been great fluctuations; in 1898 the export fell to £261,898; in 1899 it was £785,341; in 1900, £837,642; in 1901, £1,329,059; in 1904, £1,649,414; and in 1905, £1,877,318.

Railways.—The first railway was opened in 1856, and connected Adelaide with its port, and the following year saw a line constructed to Gawler, 25 m. from Adelaide. The inability of the government to borrow money at reasonable rates greatly retarded the construction of railways in the province, and in 1875 there were less than 200 m. of line: in the next ten years 800 m. were opened for traffic, and in 1905 there were 1746 m. in the state proper and 146 m. in Northern Territory. There were, in addition, 34 m. of privately owned lines. The cost of constructing and equipping the state lines stood at £14,766,465 and the net earnings at £538,890; this represents 3·64% on the capital invested. The actual interest paid by the state upon its outstanding loans was in the same year 3·79%: there was therefore a loss of 0·15% upon the working of the lines; but the state claims that the indirect benefits of railway construction far more than compensate for the direct loss. The gross earnings for the year 1905 were £1,318,521, and the working expenses £756,403; the net profit per average mile open being £297, and per train mile 34·68 pence. In 1905 the number of passengers carried was 9,870,821, and the goods tonnage 1,684,793. South Australia has two gauges, namely 508 m. of 5 ft. 3 in., and 1384 m. of 3 ft. 6 in. line. The line joining Adelaide with the Victorian border, as well as several of the trunk lines, is on the wider gauge.

Posts and Telegraphs.—In 1905 there were 711 post-offices in the state of which 299 were also telegraph stations. The business transacted was: letters and postcards transmitted, 26,230,337; newspapers, 6,717,787; packets, 1,659,775; and telegrams, 1,244,126. The total revenue from these services for the year 1905 was £274,892, and the expenditure £259,656; in these sums are included the telephone revenue and expenditure, the former amounting to £25,815. These sums are exclusive of revenue received by the Commonwealth government. The use of telephones in Adelaide is rapidly extending; in 1905 there were eleven exchanges and 2284 telephones in actual use. There were 6092 m. of telegraph line in operation in that year; the state owns the principal overland line by which communication with Europe and the East is maintained.

Banking.—The assets of all the banks of issue trading in South Australia at the end of December 1905 amounted to £7,425,775, and the liabilities to £7,623,060; these latter comprised deposits at call and at interest, £6,866,281; notes and bills in circulation, £381,573; and other liabilities £52,929. Among the assets were coin and bullion £1,861,691. The South Australian people are very thrifty, and thirty-one in every hundred have accounts with the savings banks. On the 30th of June 1905 the depositors numbered 126,821, the amount of their credit being £4,380,358, a sum equal to £34, 10s. 9d. per depositor. Taking deposits in banks of issue and in savings banks together, the total was £11,186,639, which is equal to £29, 12s. 4d. per inhabitant.

History.—Though the coast of Northern Territory was well known to Portuguese and Spanish navigators as early as perhaps 1530, being called Great Java, it was not surveyed till 1644, when Tasman laid down the line of shore pretty accurately. The western part of the southern coast had been seen and named Nuyt's Land in 1627. But Flinders, by his discovery of the two great gulfs, Kangaroo Island and Encounter Bay, in 1802, was the first to reveal South Australia proper. Captain Sturt descended the Murray in 1830, and looked over the hills near Adelaide. The first to direct attention to a settlement there was Major Baron, who communicated with the colonial office in February 1831. His suggestion was to establish, at no charge to the British government, a private company, that should settle a party on Yorke Peninsula. He believed a large river entered Spencer Gulf. In August Colonel Torrens and others proposed to purchase land between 132° and 141°—500,000 acres at 5s. an acre. Some were in favour of Spencer Gulf, others of Kangaroo Island, and a few for the mainland towards the Murray. Memorialists in 1832 sought a charter for the South Australian Association, giving extensive powers of self-government. Land sales were to pay the passages of free labour, chiefly young married people, and no convicts were ever to be sent thither. Lord Goderich did not favour the scheme, and thought a colony with free institutions might prejudice the interests of New South Wales, while free trade would interfere with the English navigation laws. After much negotiation, the English authorities regarded the scheme more favourably, but would not consent to give the company the powers they sought. The company receded in their demands, and offered security for the proper observance of law and order, while depositing cash for the purchase of land. Captain Sturt in 1834 informed the colonial secretary that Spencer Gulf and Kangaroo Island were objectionable, but that the eastern side of St Vincent Gulf was the best locality. In 1835 the ministry got an act passed for the erection of a colony under commissioners appointed by the Crown, who would be responsible for their acts to the British government. It was arranged that a local government should be established when the settlement had 50,000 people. Mr George Fife Angas advanced a large sum as security to the state. Though the first settlers were sent to Kangaroo Island, all were afterwards gathered on the Adelaide plains. The colony was proclaimed under a gum tree on the 28th of December, 1836. Great delay took place in the survey of land. The South Australian Company purchased large tracts from the commissioners at 12s. per acre and sold at 20s. A general speculative spirit arrested progress. Governor Gawler went into extravagant outlay on public buildings, &c., and drew against orders upon the English treasury. Such difficulties arose that the British rulers had to suspend the charter in 1841 and make South Australia a Crown colony. A revival of prosperity took place when the farms were tilled and poverty had taught prudence. Copper and lead mines were subsequently discovered. Kapunda in 1843, and the Burra Burra copper-mine in 1845, greatly aided in the restoration of commercial credit. The gold fever in Victoria drew off numbers in 1852; but the good prices then realized for breadstuffs gave a great impetus to farming.

In 1856 the colony was given its own constitution and self-government. On the attainment of autonomy Governor MacDonnell, in closing the last session of the then partially nominated legislature, made use of the following words: "I confidently expect that the extended political power entrusted to the people of this country, and the universal suffrage conceded by the new constitution, will prove in reality a safe and conservative measure; and whilst conferring the utmost possible power of self-government, will render stronger and more enduring than ever the cherished ties of affection and loyalty which link this province to the throne of our respected and beloved sovereign." This prediction appears to have been amply verified: South Australia enjoys the reputation of being one of the most progressive and at the same time one of the most stable of existing communities. From its origin as the venture of private enterprise the state has passed through orderly stages of evolution up to the zenith of democratic government. Such alterations as have been made in the constitution have been in the direction of a still further enlargement of the franchise. Payment of members proved to be the corollary of manhood suffrage. In 1887 a temporary act was passed for the payment of £200 a year to each member of both houses, and in 1890 the law was made permanent. Thus was rendered possible the direct representation of all classes. Soon afterwards the parliamentary Labour party came into existence; this forms a considerable proportion of the membership of both houses, and includes in its ranks men of the highest intelligence, industry and eloquence. In 1894 the principle of "one man one vote" was extended to that of "one adult one vote" by the inclusion of women as voters on terms of absolute equality with men. There is no bar to the election of women to parliament whenever the electors think fit to be so represented. The delegates to the Federal convention and to the Commonwealth parliament were in South Australia elected by the combined vote of men and women. Elections were formerly held in successive batches, but since 1893 they have taken place simultaneously in all the districts. Electoral expenses are rigidly limited, both as to objects and amount, and a declaration of money thus expended has to be filed by every candidate. Experience has demonstrated that, owing to the intrusion of the personal element, general elections have often failed to afford conclusive evidence of the state of the popular will. Attention was therefore directed towards the referendum as a means of obtaining an unquestionable verdict on important public issues, although no general statute was formulated on the subject. In 1896, at the general elections, the following questions were submitted to the electors: "Do you favour (1) the continuance of the present system of education in the state schools? (2) the introduction of scriptural instruction in the state schools during school hours? (3) the payment of a capitation grant to denominational schools for secular results?" An overwhelming majority pronounced in favour of (1) and against (2) and (3). Again, in 1899, a direct vote was similarly taken on the question of household franchise for the legislative council. Undoubtedly the practical application of the referendum in South Australia facilitated the adoption of this principle in the ratification and in the method of amendment of the Commonwealth constitution. The right of the Second Chamber to suggest amendments to bills which it has not power to amend was borrowed by the Commonwealth from the constitution of South Australia, as also was the idea of a simultaneous dissolution of both houses as a means of overcoming possible deadlocks between the chambers. As one among many improvements in parliamentary procedure may be mentioned the practice of permitting bills lapsed owing to prorogation to be replaced on the notice paper in the ensuing session by motion without debate.

Crown Lands. In partially settled countries such as South Australia the Crown lands policy rivals finance in engrossing the attention of the legislature, but as time goes on the relative importance of these subjects varies in inverse ratio. The earlier budgets, compared with those of later years, when the country had become more fully developed, might be said to resemble the finances of the nursery, whereas the initial alienations of land, comprising the most central and most valuable blocks, necessarily surpassed later transactions in significance. Many phases of public opinion as to the method of disposing of the Crown lands have been witnessed. A general review indicates clearly that the change has been uniformly in the direction of removing impediments and increasing facilities for the settlement of the people, either as freeholders or as state tenants, on the land. Under the auction system the land was allotted to the highest bidder, with the result that the payment of the purchase-money frequently exhausted the resources of the settler, and subsequent relief had to be afforded by relaxation of the conditions of the agreement to purchase. Eventually land boards were created to allot selections to applicants at low rates and deferred purchase. Perpetual leases are now taking the place of absolute alienation. The tenure is equally good for all purposes of the bona-fide settler, and capital which would otherwise be sunk in acquiring the freehold is set free for making improvements, purchasing machinery and the manifold requirements of efficient husbandry. Small blocks of 20 acres, or not exceeding £100 of unimproved value, can be obtained by working men in the vicinity of towns, thus on the one hand affording the necessary supply of agricultural labour during the busy seasons, and on the other hand providing a homestead which the holder can with advantage cultivate at slack times when unemployed. Provision was made, under the Closer Settlement Act of 1897, for the repurchase of large estates for agricultural purposes; these lands are leased to farmers at an average rent of about $4\frac{1}{8}$% on the value. The industry of wheat-growing has received an impetus through the system of drilling in a small quantity of phosphatic manure with the seed. By this means exhausted lands have been restored almost to primitive fertility. Vine-growing has now become one of the staple industries, and, owing to stringent precautions, the state remains free from the scourge of phylloxera.

Agriculture and Water. The great bulk of the unalienated land of South Australia is held in huge areas by Crown tenants, known as squatters, under pastoral leases, which now have a currency of 42 years, with security of tenure. In 1893, when the unemployed were very numerous, the government established co-operative village settlements on tracts of land adjoining the river Murray. Seven of these are now in existence as irrigation colonies. The water is raised from the river by rotary pumps, and distributed by means of channels, after the plan adopted at Renmark. By the application of water to the adjacent sun-steeped soil miles of worthless mallee scrub have been converted into vistas of vineyards, orange groves and orchards. The paramount importance of water-supply and conservation has received ever-increasing recognition. The Beetaloo reservoir has a capacity of 800,000,000 gallons, and from its 695 m. of trunk mains a district of over 1,000,000 acres is reticulated. The supply of Adelaide and its vicinity has been reinforced by a reservoir at Happy Valley, having a contour of about $7\frac{1}{2}$ m. at high-water mark, and containing 2,950,000,000 gallons. The reservoir was formed by the construction of an earthen embankment 2645 ft. long and 72 ft. high; this is filled from the Onkaparinga river through half a mile of steel main, 6 ft. in diameter, and $3\frac{1}{2}$ m. of tunnel. Works on a large scale have also been constructed at Bundaleer and Barossa. The custom for many years past has been to construct these and other great public works departmentally instead of by contract. Many artesian wells have been sunk on the routes for travelling stock in the interior. The bores of some of these exceed 3000 ft. in depth, and the supply varies from 200,000 to 1,000,000 gallons a day. Around some of these wells in the far north plantations of date-palms have yielded excellent results.

South Australia was founded when the tide of the *laissez-faire* régime was running high, and a patriotic bias in the customs tariff was regarded as an unwarrantable restriction; it is therefore not surprising that free trade should at the outset have received many adherents. There were not wanting, however, some who saw clearly that a country almost entirely occupied in primary production would prove but a barren field for the cultivation of the many-sided activity necessary to a complete national life. It was also maintained that if inducements were given to capital to embark in home industries, a cheapening of the product, due to approximation of supply and demand, would ensue. In accordance with these views, a protective tariff was adopted in 1885. Two years later the duties were increased and extended. The establishment of manufactures and new industries opened a career for youths of inventive and mechanical aptitude, and in several instances the predicted reduction in price of the protected article has been strikingly manifested.

Government Enterprise. One of the most notable developments in public policy consisted in the extension of the sphere of the state so as to embrace activities formerly considered to be solely within the province of private enterprise. Railways from the outset have been government undertakings, so also have been waterworks of any degree of magnitude; telegraphs and telephones, taken over by the Commonwealth, have always been regarded as state monopolies. A public trustee undertakes, when desired, the administration of estates. In 1895 a state bank was established to provide farmers with the necessary working capital at lowest current rates of interest. A state produce dépôt was also organized at the same time to assist farmers in placing their produce to the best advantage on the world's markets. Produce is received by the department of agriculture, prepared for shipment, certified as to quality, and graded. Small parcels from a number of producers are grouped together in one consignment and shipped at the lowest rates. The government of South Australia also undertakes, if so desired, to act as agent in London for the consignor, and to arrange for the sale of his produce; so that a farmer who has no representative at the port of destination, but is desirous of ascertaining whether a profitable trade can be established in any class of produce, has only to send the goods to the dépôt, and await the arrival of a cheque when the sales accounts come to hand. An advance amounting to three-fifths of the value of the produce at 5% is made if desired. Wine shipped through the produce dépôt is analysed and examined in bulk by government experts, and if found to be both sound and pure is sent to the bonded dépôt in London with a certificate to that effect: this is recorded on the label of the bottles in which it is retailed, under the name of the "Orion" brand. Cyanide works have been erected in various centres for treating ore raised by miners working in the neighbourhood. State smelters for copper ore have been built at Port Augusta, but are not now in operation. There is a Factory Act permitting the establishment of wages boards, and also legislation providing for a weekly half-holiday and the early closing of shops. A compulsory Conciliation Act deals with the prevention and settlement of industrial disputes. The Right Hon. C. C. Kingston was the pioneer in Australasia of legislation of this description. These measures were at first denounced by some as Socialistic, and were regarded by many as an undue interference with private enterprise. Some of the state aids were, however, speedily recognized as affording additional incentives to industry, and by enabling producers and workers to obtain a better return for their labour may fairly be held to have assisted rather than to have retarded private enterprise. In 1893 a bonus on butter exported to the world's markets was successful in bringing into existence a fully equipped export trade. Public opinion in South Australia has little tolerance with laxity. Children are prevented from selling articles in the streets after 8 p.m., and are not allowed to fetch beer from public-houses. The age of consent has been raised to 17 years. The notification by medical men of cases of pulmonary tuberculosis to the local authorities is compulsory.

Education. No pains have been spared to keep pace with modern improvements in popular education as an indispensable feature in democracy. South Australia holds in reverent and loving memory the name of John Anderson Hartley, the originator of the state school system, who died in 1896, and to whose character as a man and genius as an organizer the schools of South Australia will remain as a perennial monument. School fees for children under the compulsory age of 13 were abolished in 1891, and in 1898 the older children were also admitted free. Students in training have now the advantage of a two-years' course at the university. Technical education has received much attention. A foundation was long ago laid in the primary schools by the inclusion of drawing as a compulsory subject, and by affording facilities for manual training. In 1889 the South Australian School of Mines and Industries was established, and under the presidency of Sir Langdon Bonython proved a most valuable institution. Other technical schools are in operation in industrial and mining centres. A reserve of 2 acres is attached to all new country schools, and systematic lessons in practical agriculture are given by many teachers. In order to encourage tree-planting, a yearly school holiday devoted to this purpose, and known as Arbor Day, was established in 1886. With a similar object the state has distributed, free of charge, 5,000,000 forest trees to 21,000 persons. Over 1,250 000 vines have also been given away. The boys' field club (1887), with the motto "The Naturalist loves Life," under the direction of Mr W. C. Grasby, was one of the pioneers of Nature-study. A state secondary school for girls has been for many years self-supporting, and in 1897 secondary agricultural schools for boys were organized in Adelaide and other centres. Half the school hours of each day are spent in the class-room, the remainder being devoted to workshop, field and laboratory practice. An agricultural college at Roseworthy, 25 m. north of Adelaide, imparts a high-class theoretical and practical training in the various branches of agriculture, including viticulture and wine-making. The fee charged is £30 a year, including board and lodging. Information as to practical and scientific husbandry is disseminated among the farmers by means of an agricultural bureau, with numerous branches throughout the country. A journal is published conjointly by the departments of agriculture and industry, containing reports of the proceedings of the bureaus and articles by government experts, together with industrial topics and matters of interest to artisans, and also particulars furnished by the labour bureau as to prospects of employment in various districts. (J. A. Co.)

SOUTH BEND, a city and the county-seat of St Joseph county, Indiana, U.S.A., at the head of navigation and on the southern bend (hence the name) of the St Joseph river of Michigan, and (by rail) 86 m. E. by S. of Chicago. Pop. (1900), 35,999, of whom 8601 were foreign-born (including 3053 Poles and 2402 Germans); (1910, census), 53,684. Land area (1906), 6·2 sq. m. It is served by the Grand Trunk, the Lake Shore & Michigan Southern, the Michigan Central, the New Jersey Indiana & Illinois, the Chicago, Indiana & Southern, and the Vandalia railways, and by four inter-urban electric lines. Among the principal buildings are the city-hall, the county court-house, the public library, and the Oliver Hotel. In Notre Dame, a suburb, are St Mary's College and Academy (Roman Catholic, chartered 1855) for girls, and the university of Notre Dame du Lac (Roman Catholic, first opened in 1842, and chartered in 1844). In 1910 the university had 87 instructors, 1005 students, and a library of 60,000 volumes. It is the headquarters of the order of the Holy Cross, whose sisters have charge of St Mary's College and Academy. South Bend ranked fourth among the manufacturing cities of the state in 1905. Its industrial establishments include carriage and wagon works (those of the Studebaker Bros. Manufacturing Company being the largest in the world), plough and agricultural machine works—the Oliver Chilled Plow Works, founded by James Oliver (1823–1909), being particularly well known—the wood-working department of the Singer Sewing Machine Company, iron and steel foundries, flour-mills, and paper and pulp mills. The water-supply is obtained from 122 artesian wells, with a daily capacity of about 24,000,000 gallons. South Bend was the site of an Indian village and of a French trading post. It was settled about 1820, laid out about 1831 (when it became the county-seat of St Joseph county), incorporated as a village in 1835, and chartered as a city in 1865.

SOUTH BETHLEHEM, a borough of Northampton county, Pennsylvania, U.S.A., on the Lehigh river, about 57 m. N.W. of Philadelphia, and opposite Bethlehem, with which it is connected by bridges. Pop. (1900), 13,241, of whom 3322 were foreign-born and 115 were negroes; (1910 census), 19,973. It is served by the Lehigh Valley, the Philadelphia & Reading, the Central of New Jersey and the Lehigh & New England railways. The borough is the seat of Lehigh University. This institution was founded in 1865 by Asa Packer, who then gave $500,000 and 60 acres (afterwards increased to 115 acres) of land in the borough, and by his will left to the university library $500,000, and to the university an endowment of $1,500,000 and a large interest (about one-third) in his estate. The university was chartered in 1866; it embraces a school of technology, with courses in civil, mechanical, metallurgical, mining, electrical and chemical engineering, electrometallurgy and chemistry, and a school of general literature (1878), with classical and Latin-scientific courses. In 1908–1909 it had 68 instructors, 1720 students, and a library of 127,000 volumes. The principal buildings of the university are Packer Hall (1869), largely taken up by the department of civil engineering, the chemical and metallurgical laboratory, the physical and electrical engineering laboratory, the steam engineering laboratory, Williams Hall for mechanical engineering, &c., Saucon Hall for the English department Christmas Hall, with drawing-rooms and the offices of the Y.M.C.A., the Sayre astronomical observatory, the Packer Memorial Church, the university library (1897), dormitories (1907) given by Andrew Carnegie, Drown Memorial Hall, a students' club, the college commons, and a gymnasium.

South Bethlehem is the see of a Protestant Episcopal bishop. The Bethlehem Steel Company manufactures here iron and steel, including Bessemer steels, armour plate, steel rails, government ordnance, drop forgings, iron and steel castings, stationary engines, gas engines, hydraulic pumps, projectiles, steel shaft and pig iron; zinc is smelted and refined; and there are large hosiery and knitting mills, and silk mills and cigar factories. The total value of the borough's factory products increased from $9,964,054 in 1900 to $15,275,411 in 1905, or 53·3%.

In 1846 a water-cure was established where St Luke's hospital now stands, in the adjoining borough of Fountain Hill (pop. in 1910, 1388), and for a few years this attracted a considerable number of visitors during the summer season. In 1853 works were established for the manufacture of white oxide of zinc from a calamine found here, in the next year metallic zinc was produced, and in 1865 the first sheet zinc made in America was rolled here. The borough was incorporated in 1865.

SOUTHBRIDGE, a township of Worcester county, Massachusetts, U.S.A., on the Quinabaug river (which here falls 165 ft.), about 20 m. S.S.W. of Worcester. Pop. (1900), 10,025, of whom 3468 were foreign-born; (1910 census), 12,592. Area, about 20 sq. m. The township is served by the New York, New Haven & Hartford railway, and by inter-urban (electric) lines to Worcester and Springfield. The Southbridge public library (1870) contained 22,000 volumes in 1910. Optical goods, cotton, woollen and print goods, cutlery and shuttles are the principal manufactures; in 1905 the value of the total factory product was $4,201,853. The factory of the American Optical Company here is probably the largest of its kind in the world.

In 1801 a poll parish, named the Second Religious Society of Charlton, and popularly called Honest Town, was formed from the west part of Dudley, the south-west part of Charlton and the south-east part of Sturbridge; and in 1816 this parish became the township of Southbridge.

See the *Leaflets* published (1901 sqq.) by the Quinabaug Historical Society of Southbridge.

SOUTH CAROLINA, a South Atlantic state of the United States of America, and one of the original thirteen, lying between latitudes 32° 2′ and 35° 17′ N. and between longitudes 78° 30′ and 83° 20′ W. It is bounded N. by North Carolina, E. by North Carolina and the Atlantic Ocean, S.E. by the Atlantic Ocean, S.W. and W. by the Savannah, Tugaloo and Chattooga rivers, which separate it from Georgia. Its total area is 30,989 sq. m., and of this 494 sq. m. are water surface.

Surface Features.—South Carolina is mainly in the Coastal Plain and Piedmont Plateau regions, but in the north-west it extends slightly into the Appalachian Mountain region. Locally the Coastal Plain region is known as the low country, and the Piedmont Plateau and Appalachian Mountain regions are known as the up-country. The coast, about 200 m. in length, is generally low. For 60 m. south-west of the North Carolina border it is unbroken and lined with a smooth, hard beach of light-coloured sand, but below this it becomes increasingly broken by estuaries and is lined with flat and low sea-islands that increase in size and number toward the Georgia border. For about 10 m. back from the coast the Coastal Plain region is occupied very largely by salt marshes. Then, although still continuing flat, the surface rises at the rate of about 2½ ft. per mile for 40 m. or more; beyond this it rises more rapidly, reaches a maximum elevation in Lexington county of about 700 ft. above the sea, and becomes increasingly broken into rolling plateaus and deep valleys to the Fall Line, which marks the boundary between the Coastal Plain and the Piedmont Plateau. This line, at which the south-east flowing rivers fall from higher levels in the crystalline rocks of the Piedmont Plateau down to somewhat lower levels in the softer rocks of the Coastal Plain, passes in a general south-west direction from the North Carolina border north-east of Cheraw through Camden and Columbia to the Savannah river opposite Augusta, Georgia. The Piedmont Plateau region, rising gradually from an elevation of about 500 ft. along the Fall Line to 1000 ft. or more in the north-west, is a plateau broken into undulating ridges and deeply cut valleys. In the small section of South Carolina which is traversed by the Appalachian Mountain region a few mountains of the Blue Ridge rise abruptly from the foot-hills to 3413 ft. in Mt Pinnacle, 3218 ft. in Caesars Head, and 3157 ft. in Table Rock. The highest point in the state is Sassafras Mountain (3548 ft.) in the Blue Ridge and on the North Carolina state line. The mean elevation of the entire state is about 350 ft. The principal rivers rise in the Appalachian Mountains and flow south-east into the Atlantic Ocean. In the middle section the Santee river is formed by the confluence of the Wateree, which is known in North Carolina as the Catawba, and the Congaree, which is in turn formed by the Broad and the Saluda, and the basin of this system embraces about one-half the area of the state. In the north-east the Great Pedee and its tributaries—the Little Pedee, Waccamaw and Lynches—are wholly within the Coastal Plain, but the main stream is a continuation below the Fall Line of the Yadkin river, which rises in the mountains of North Carolina. On the Georgia border the Chattooga river, rising in the Blue Ridge, becomes tributary to the Tugaloo, which in turn becomes tributary to the Savannah. The Combahee and the Edisto, in the south-east, and the Black, north of the Santee, are the principal rivers that rise within the Coastal Plain and flow direct to the ocean. In the Piedmont Plateau region the current of the rivers is usually swift, and not infrequently there are falls or rapids; but in the Coastal Plain region the current becomes sluggish, and in times of high water the rivers spread over wide areas.

Fauna.—The principal animals and birds in South Carolina are deer, rabbits, squirrels, opossums, musk-rats, raccoons, minks, geese, ducks, wild turkeys, "partridge" (quail or bobwhite), woodcock and snipe. Foxes, bears, wolves, lynx (wild cats) and otters are very rare, and pumas (panthers) and beavers long ago disappeared. Common among birds of prey are owls, hawks and kites, and there are many turkey buzzards. Song birds are numerous and of many varieties; among them are thrushes, mocking birds, blue birds, robins, wrens, chickadees, warblers, vireos, sparrows, bobolinks (reed birds or rice birds), meadow larks and orioles. In the bays and lower courses of the rivers are porpoises, whiting, sea bass, channel bass, shad, sturgeon, mullet, drum, bluefish, snappers, sheepshead, weakfish or squeteague, groupers, and several other kinds of fish. Oysters, crabs, shrimp and terrapins are also abundant here, and in the inland streams are some pike, perch, trout and catfish.

Flora.—From the number of palmettoes along the coast South Carolina has become popularly known as the Palmetto state. Scarcely less conspicuous for some distance from the ocean are the magnolias, the live oaks draped with long gray moss, and the reed-covered marshes. In the swamps there are cypresses and some gum and bay trees. In most of the uplands of the Coastal Plain region the long-leaf pine is predominant, but large water-oaks and undergrowths of several other oaks and of hickories are not uncommon. On the Piedmont Plateau and in some of the more hilly and heavy-soil sections below the Fall Line there is some short-leaf pine, but most of the trees in these sections are of the hardwood varieties: deciduous oaks are most common, but beech, birch, ash, maple, black walnut, chestnut, sycamore and tulip trees also abound. On the mountains are the cucumber tree, laurel, white pine and hemlock. Among indigenous trees, shrubs and vines that bear edible fruits or nuts the state has the blackberry, grape, pawpaw, persimmon, plum, crabapple, hickory, chestnut and hazel nut. The English walnut, pecan, apple, apricot, pear and cherry are also cultivated. Both medicinal and flowering plants are exceptionally abundant; a few of the former are ginseng, snakeroot, bloodroot, hore-hound, thoroughwort, redroot (*Ceanothus Americanus*), horse mint and wild flax, and prominent among the latter are jessamines, azaleas, lilies, roses, violets, honey-suckle and golden-rod. Venus's flytrap is found along the coast.

Climate.—Along the coast the climate is comparatively mild and equable. At Charleston, for example, the mean winter temperature is 51° F., the mean summer temperature 81° F., the mean annual temperature 66° F., and the range of extremes from 104° F. to 7° F. or 97° F. Toward the north-west the mean winter temperature decreases to 47° F. at Columbia and to 40° F. at Greenville; the mean summer temperature decreases only to 80° F. as far as Columbia, but from there to Greenville decreases to 75° F.; and the mean annual temperature decreases to 62° F., at Columbia and to 58° F. at Greenville. The range of extremes increases to 108° F. (106° to −2°) at Columbia, and then decreases to 102° F. (97° to −5°) at Greenville. The greatest range of extremes in the state is from 11° F. at Santuck, Union county, in February 1899, to 106° F. at Columbia in August 1900. For the whole state the mean annual temperature is about 63° F., the mean summer temperature 79° F., and the mean winter temperature 44° F. In nearly all sections January is the coldest month and July the warmest. The mean annual rainfall for the state is about 49 in., and its distribution is excellent. Extremes for the various sections range only from 53·4 in. at Charleston to 44·4 in. at Stateburg, in Sumter county. Seventeen inches, or more than one-third, falls during the summer, and for the other seasons the range is only from 10·1 in. for autumn to 11·6 in. for winter. Snow is uncommon in the south-east of the state, and whenever there is a snow-storm the snow usually melts as it falls; but in the centre and north-west occasionally covers the ground to a depth of several inches. The prevailing winds are from the south-west along the coast, from the north-east in the north-central section, and from the west in the west section. Tornado winds sometimes occur in the west section, and the east section occasionally suffers from West Indian hurricanes.

Soils.—In general the soils of the Piedmont Plateau region are such as have been formed by the disintegration of the underlying rocks. These consist mostly of granite and gneiss, but in the north-central section there is trap-rock, and in the south-east section some slate. On the more level areas of the Piedmont Plateau the granitic soil is a grey mixture of sand and clay, but on the hillsides of the river basins it is a heavy clay of reddish colour, the sand having been washed down to form the soils of the Coastal Plain. In all sections of the Piedmont Plateau the subsoil is a reddish or yellowish clay. In the upper section of the Coastal Plain region the soil is for the most part a loose sand, but lower down it becomes finer, more tenacious, and consequently more fertile.

Agriculture.—The number of farms in South Carolina was 93,864 in 1880, 115,008 in 1890 and 154,166 in 1900—the number for the two last named years not including farms of less than 3 acres and of relatively small productivity. The total acreage in farms in 1880 was 13,457,613 acres, of which 4132 acres were improved; in 1890, 13,184,652 acres, of which 5,255,237 acres were improved; and in 1900, 13,985,014 acres, of which 5,755,741 acres were improved. The total value of farm property, with improvements, machinery and livestock, was $84,079,702 in 1880; $119,849,272 (average value per farm, $1042) in 1890; and $153,591,159 (average value, $989) in 1900; while the average value per acre of farm-land increased from $9.09 in 1890, to $10.98 in 1900. Of farms of 1000 acres and more there were 1635 in 1880 and 1010 in 1900; of between 500 acres and 1000 acres there were 3693 in 1880 and 2314 in 1900; of 50 acres and less than 100 acres there were 13,612 in 1880 and 29,944 in 1900; of 20 acres and less than 50 acres there were 3688 in 1880 and 5261 in 1900. Farms worked by owners numbered 46,645 in 1880 and 60,471 in 1900; by cash tenants, 21,974 in 1880 and 57,046 in 1900; by share tenants, 25,245 in 1880 and 37,838 in 1900. Of the 155,355 farms in the state in 1900, 85,381 were worked by negroes of whom 22·2% were owners of their farms, 49·7% cash tenants and 27·9% share tenants.

The state long out-ranked all other states in the growing of rice, but this industry has declined, and South Carolina is now surpassed by both Louisiana and Texas. Cotton is the state's most valuable crop. The cotton product of the state in 1889 was 747,190 bales, in 1899 it was 881,422 bales, and in 1909, 1,095,000 bales. The principal cereals, with the amounts and values of the crops in 1899 and 1909 are: Indian corn, 17,429,610 bush. ($9,149,808) in 1899 and 37,041,000 bush. ($33,337,000) in 1909; wheat, 1,017,319 bush. ($958,158) in 1899 and 3,810,000 bush. ($5,563,000) in 1909. Oats, 2,661,670 bush. ($1,226,575) in 1899 and 4,431,000 bush. ($3,190,000) in 1909. Rice, 47,360,128 ℔ ($1,366,528) in 1899, on 23,726 farms, nearly half of the total number (48,155) of rice farms in the United States, which, however, decreased to 476,000 bush. ($433,000) in 1909. The rye crop was 19,372 bush. ($18,405) in 1899, and 39,000 bush. ($55,000) in 1909. Other important crops are: tobacco 19,895,970 ℔ ($1,297,293) in 1899, and 32,000,000 ℔ ($2,336,000) in 1909; hay and forage, 213,249 tons ($2,304,734) in 1899, and of hay alone 81,000 tons ($1,256,000) in 1909; potatoes, 3,369,957 bush. ($1,538,205) in 1899 and 765,000 bush. ($880,000) in 1909.

Mining.—The value of the mineral product of the state was $1,834,134 in 1902, $2,305,203 in 1907 and $2,081,001 in 1908. The total value of the products of manufacturing industries based on mining was $18,565,682 in 1900, or 17·2% of the total value of the product of all manufacturing industries. The most valuable single mineral is phosphate rock, which is found in a belt 70 m. long by 30 m. wide, extending from the mouth of the Broad river near Port Royal in the south-east to the headwaters of the Wando river in the north-east. The chief deposits are found in Berkeley, Dorchester, Charleston, Colleton and Beaufort counties, at the bottom of rivers, 20 to 30 ft. in depth, and on land at an elevation but little above mean tide. Its commercial value for the manufacture of fertilizer was established in 1867, and the mining of it began soon afterwards in the Ashley River region. The amount mined in 1868 was 12,262 long tons; in 1902, 313,365 long tons; and in 1908, 225,495 long tons, valued at $989,881. The value of other minerals produced in 1908 was as follows: Granite, $297,874; clay, $110,636; and monazite, $13,494. The product and value of mineral waters was 786,754 gals. ($195,182) in 1907 and 271,572 gals. ($70,937) in 1908. Minerals which were not mined commercially in 1902 include asbestos, which occurs in Spartanburg and Pickens counties; fullers'-earth: graphite in Spartanburg and Greenville counties; iron ores in the north and north-west portions of the state; iron pyrites in Spartanburg and York counties; talc, bismuth, ochre, pyrites, galena, brown coal, malachite, phosphate of lead and barytes.

Manufactures.—The number of factories in South Carolina in 1900 was 1369, in 1905, 1399[1]; the amount of capital invested in such establishments was $62,750,027 in 1900, and in 1905 $113,422,224; the value of products in 1900 was $53,335,811; in 1905, $79,376,262; and the average number of wage earners in

[1] The special census of 1905 was confined to manufactures under the factory system, and the statistics above for 1900 have been reduced to the same standard to make them comparable with the statistics for 1905.

1900, 47,025, and in 1905, 59,441. Except in number, the rural establishments showed greater increases than the urban.[1] The number of rural establishments in 1900 was 1174; in 1905, 1179; and the number of urban establishments in 1900, 195; in 1905, 220; but the capitalization of the rural establishments increased from $50,057,922 in 1900 to $97,942,185 in 1905; while that of the urban increased from $12,692,105 to $15,480,039; the value of the products of the rural establishments increased from $41,930,816 to $64,887,748; while that of the urban establishments increased from $11,404,995 to $14,488,514; and the number of employés in rural establishments increased from 36,616 to 50,744, while those in urban establishments increased from 7409 to 8697. More than half of the manufacturing establishments were engaged in the manufacture of cotton goods, of lumber and timber, of fertilizers, of cotton-seed oil and cake, of lumber and planing-mill products, of cars and general shop construction, and of hosiery and knit goods.

The manufacture of cotton goods was much the most important industry in 1900 and 1905, and showed a remarkable growth. The capital invested in this industry was $39,258,946 in 1900 and $82,337,429 in 1905; the value of the products was $29,723,919 in 1900 and $49,437,644 in 1905; the average number of wage-earners was 30,201 in 1900 and 37,271 in 1905; and the amount of wages, $5,066,840 in 1900 and $7,701,689 in 1905. The number of establishments in 1900 was 80, and in 1905, 127; the number of producing spindles in 1900 was 1,431,349, and in 1905, 2,864,092; and the number of looms in 1900, 42,663, and in 1905, 72,702. The use of domestic cotton increased from 485,024 bales in 1900 to 555,467 bales in 1905, and the amount paid for this cotton increased from $14,909,520 to $30,451,159. In the same period the amount of foreign cotton used increased from 210 bales in 1900 to 2633 bales in 1905, and the amount paid for it from $20,026 in 1900 to $318,020 in 1905. The principal product of the mills was plain cloths for printing or converting, of a quality finer than No. 28 warp, of which there were produced 322,850,981 sq. yds., valued at $14,007,496 in 1905, as compared with 97,343,526 sq. yds., valued at $3,171,198 in 1900. Other products and their values in 1900 and 1905 were as follows: brown or bleached sheetings and shirtings, 283,105,383 sq. yds. ($11,553,073) in 1900 and 248,777,474 sq. yds. ($12,035,854) in 1905; yarns for sale, 24,859,616 ℔ ($3,461,090) in 1900 and 31,645,397 ℔ ($6,217,795) in 1905; drills, 116,467,224 sq. yds. ($5,375,017) in 1900 and 88,551,799 sq. yds. ($5,344,146) in 1905; twills and sateens, 11,379 712 sq. yds. ($485,484) in 1900 and 45,220,488 sq. yds. ($2,175,651) in 1905.

The value of the products of other industries in 1900 and 1905 were as follows: Lumber and timber, $4,942,362 in 1900 and $6,791,451 in 1905; cotton-seed oil and cake, $3,103,425 in 1900 and $5,462,818 in 1905; fertilizers, $4,882,506 in 1900 and $3,637,576 in 1905; lumber and planing-mill products, including sash, doors and blinds, $1,016,328 in 1900 and $1,478,581 in 1905; hosiery and knit goods, $392,237 in 1900 and $1,078,682 in 1905; cars and general shop construction and repairs by steam railway companies, $691,361 in 1900 and $1,080,990 in 1905.

Forests.—The principal lumber resource of South Carolina is yellow (or "southern") pine, and there is also a small quantity of cypress. The stand of yellow pine in the state in 1880 was estimated at 5316 million ft.; and in 1905 it was estimated at 3363 million ft. The value of the lumber product increased from $1,108,880 in 1850 to $5,207,184 in 1900. Some use is also made of the forest resources of the state in the manufacture of veneer, paper pulp, turpentine and other chemicals.

Fisheries.—The total yield of the state's fisheries in 1902 was 8,174,463 ℔, valued to the fishermen at $263,023, which is an increase over that of 1897 of 2,894,017 ℔ and of $52,567 in value. The number of persons employed in 1902 was 3713, an increase over 1897 of 1574; the amount of capital invested in 1902 was $320,723, an increase over 1897 of $146,369. The oyster fishery represented in 1902 about 45% of the entire value of the state's fisheries, the catch in that year being 689,700 bush., valued at $118,460, an increase over 1897 of 474,800 bush. and $73,100. The amount and value of other catches in 1902 were as follows: whiting, 606,300 ℔ ($30,118); sea bass, 709,545 ℔ ($27,364); shad, 434,133 ℔ ($20,782); clam, 28,133 bush. ($12,940); shrimp, 306,500 ℔ ($12,452); terrapin, 27,521 ℔ ($5,580); mullet, 138,000 ℔ ($3782); jewfish, 79,500 ℔ ($3738); channel bass, 102,000 ℔ ($3550); squeteague, 85,700 ℔ ($3059); shark, 90,000 ℔ ($1800). Other fish taken include the sheepshead, drum, grouper, striped bass and croaker.

Transportation.—The chief railway systems of South Carolina are the Southern, the Seaboard Air line and the Atlantic Coast line. The railway mileage of the state was 3335·48 m. on the 1st of January 1909. Inland water communication is furnished by several navigable rivers. Between 1816 and 1826 the state expended upon internal improvements $1,712,626, a large part of which was appropriated for building canals round the rapids of five rivers; between 1878 and 1900 the United States government expended $6,063,692 upon seven rivers and three harbours. The Savannah River is navigable from Savannah to Augusta, Georgia (202 m.), where its mean low water depth is 3 ft., and from Augusta to Petersburg, Georgia, for flatboats. Other navigable streams are the Waccamaw, to Bucksville (50 m.); the Great Pedee to Smith's Mills (52 m.); the Cooper, to Strawberry Ferry (30 m.); the Ashley, to Lambs (13 m.); the Edisto, to Guignard Landing (260 m.); the South Edisto, to the North Edisto (11 m.); the Beaufort, to the Coosaw River (11 m.); and the Santee, to the confluence of the Congaree and Wateree rivers, which are navigable for flatboats. The ports of entry are Charleston, Beaufort and Georgetown.

Population.—The population in 1880 was 995,577; in 1890, 1,151,149; in 1900, 1,340,316; and in 1910, 1,515,400.[2] In only one other state, Mississippi, in 1900 the negroes exceeded the whites; in South Carolina 58·4% of the total, or 782,321, were negroes or of negro descent, and 41·6% were whites; but there was a slight falling-off in the percentage of negroes, this having been 59·9% in 1890. Of the total population, 99·6% were native-born. There were, in 1900, 552,436 native whites; 5,528 persons of foreign birth, 121 Indians and 67 Chinese. Of the inhabitants born in the United States, 29,521 were natives of North Carolina, and 13,544 were natives of Georgia, and of the foreign-born 2075 were Germans, and 1131 were natives of Ireland. Of the total population, 17,628 were of foreign parentage—*i.e.* either one or both parents were foreign-born—and 2503 were of German and 1607 of Irish parentage on both the father's and the mother's side. In 1906 there were in the state 655,933 members of different religious denominations, of whom the Baptist bodies were the strongest with 341,456 communicants; the Methodist bodies had 249,169 members; 35,533 were Presbyterians; 12,652 were Lutherans; 10,317 were Roman Catholics; and 8557 were Protestant Episcopalians. From 1890 to 1900 the urban population (*i.e.* in places with 4000 inhabitants) increased from 84,459 to 157,111; the semi-urban population (*i.e.* population of incorporated places), or the approximate equivalent, having less than 4000 inhabitants) increased from 93,551 to 104,352; while the rural population (*i.e.* population outside of incorporated places) increased from 973,139 to 1,078,853. The principal cities are Charleston, Columbia (the capital), Spartanburg, Greenville, Sumter, Anderson and Rock Hill.

Administration.—South Carolina was governed from 1670 to 1719 under the Carolina provincial charter of 1665, from 1719 to 1776 under commissions and instructions from the Crown, and after 1776 under the constitutions of 1776, 1778, 1790, 1865, 1868 and 1895. An amendment to the constitution may be proposed by either house of the legislature; if it is approved by two-thirds of the members elected to each it must then be submitted to the people to be voted on at the next general election for members of the state house of representatives, and if it receives a favourable vote of a majority and subsequently a majority vote in each house of the next general assembly it becomes part of the constitution. A constitutional convention to revise the constitution may be called by a two-thirds vote in each house, subsequently ratified by a majority vote of the electors of the state.

Effective protection against a possible restoration of negro rule seems to have been aimed at in the suffrage provisions of the new constitution. Two plans of registration were provided, one temporary, the other permanent. Up to the 1st of January 1898 all persons otherwise qualified could register, provided they could read any section of the constitution or understand and explain it when read to them by the registration officer, and all persons so registered were qualified voters for life. The obvious intention was to disfranchise illiterate negroes, but not illiterate whites. Under the permanent plan, however, this distinction will gradually disappear. Those who should apply for registration after the 1st of January 1898 must be able to read and write any section of the constitution submitted to them by the registration officer, or must show that they have paid all taxes for the previous year on property worth $300 or more. Other requirements for voters

[1] In this class are included the manufactures of only four cities, Charleston, Columbia, Greenville and Spartanburg, which in 1900 had populations of 8000 or more.

[2] According to previous censuses the population was as follows: 1790, 249,073; 1800, 345,591; 1810, 415,115; 1820, 502,741; 1830, 581,185; 1840, 594,398; 1850, 668,507; 1860, 703,708; 1870, 705,606.

are: residence in the state for two years (except that ministers in charge of organized churches and teachers of public schools need have a residence in the state of six months only), in the county for one year, and in the polling precinct for four months, and the payment six months before election-time of a poll-tax. Idiots, insane persons, paupers, convicts and persons convicted of certain crimes (enumerated in the constitution) and not pardoned by the governor are disqualified from registering or voting.

Under the constitution of 1895 the governor holds office for two years and is eligible for re-election. The governor and the lieutenant-governor must be thirty years old and must have been citizens of the United States and citizens and residents of the state for five years. The governor has a veto power, extending to the separate items in appropriation bills, which may be overcome by a two-thirds majority in each house of the General Assembly; three days (excluding Sunday) are allowed to the governor for vetoing bills or joint resolutions passed by the General Assembly, or only two days if the General Assembly adjourn before three days have elapsed. The lieutenant-governor is the presiding officer of the senate, and succeeds the governor if the governor is removed from office by impeachment, death, resignation or otherwise. Other administrative officers of the state, each elected for two years, are a secretary of state, a comptroller-general, an attorney-general, a treasurer, an adjutant and inspector-general, and a superintendent of education.

The state legislature is officially styled the General Assembly, and is composed of a Senate and a House of Representatives. The House of Representatives is composed of 124 members elected every two years and apportioned among the counties according to population; the Senate of one member from each county, elected for a term of four years, the term of one-half of the senators ending every two years. Annual sessions of the General Assembly are held, beginning on the second Tuesday in January. In 1904 the legislature submitted an amendment providing for biennial sessions and it was ratified by a popular vote, but inasmuch as the constitution requires a subsequent ratification by the legislature, the question came up again in the session of 1905. Attention was then called to the fact that the new amendment would make other changes in the constitution necessary, and the matter was referred to a legal commission.

The judicial power is vested in a Supreme Court and two circuit courts, a court of common pleas having civil jurisdiction, and a court of general sessions having criminal jurisdiction. The supreme court consists of a chief justice and three associates, elected by a joint viva voce vote of the General Assembly for a term of eight years. In each of the eight circuits is a circuit judge elected in a similar manner for four years. The magistrates or justices of the peace are appointed by the governor—a wise provision, because under the constitution of 1868 negroes were frequently elected who could neither read nor write.

Local Government.—The unit of local government in South Carolina is the county, which, the state constitution provides, "shall be a body politic and corporate." The constitution also provides for the establishment of a new county, "whenever one-third of the qualified electors within the area of each section of an old county proposed to be cut off to form a new county shall petition the governor for the creation of a new county," whereupon the governor "shall order an election within a reasonable time thereafter," and if two-thirds of the voters vote "yes," the General Assembly at the next session shall establish the new county, provided that no section of a county shall be cut off without the consent of two-thirds of those voting in such section; that no new county "shall contain less than one one hundred and twenty-fourth part of the whole number of inhabitants of the state, nor shall it have less assessed taxable property than one and one-half millions of dollars, nor shall it contain an area of less than four hundred square miles"; and that "no old county shall be reduced to less area than five hundred square miles, to less assessed taxable property than two million dollars, nor to a smaller population than fifteen thousand inhabitants." The General Assembly may alter county lines at any time, provided the proposed change is sanctioned by two-thirds of the voters in the section proposed to be cut off. The General Assembly may also provide for the consolidation of two or more counties if a majority of the voters concerned approve, "but such election shall not be held oftener than once in four years in the same counties." Counties are divided into townships and under the constitution each "shall constitute a body politic and corporate," but in 1910 there were no separate township governments, the existing division of counties into townships being for the purpose of convenience in adjusting taxes. Municipal government machinery is prescribed by a general state law which provides for the acquirement by municipalities of waterworks and lighting-plants, the levying and collection of taxes and the issuing of licences, and regulates bonded debts. Cities and towns are permitted to exempt, by ordinance, certain classes of manufactories from all taxes except for school purposes, provided such ordinances are ratified by a majority of the electors.

Miscellaneous Laws.—The elaborate precautions taken to prevent lynching are a peculiarity of the constitution of 1895. Any officer—state, county or municipal—who, through negligence or connivance, permits a prisoner to be seized and lynched, forfeits his office and becomes ineligible to hold any office of trust or profit in the state unless pardoned by the governor. The county in which the crime occurs is, without regard to the conduct of the officers, liable in damages of not less than $2000 to the legal representative of the person lynched; the county is authorized, however, to recover this amount from the persons engaged in the lynching. A fourth unusual feature is that South Carolina has applied the principle of direct primary nominations to all elective officials from governor down. United States senators are in practice elected by the people, for the legislature merely registers the result of the primary. Since an absolute majority of the votes cast is required, it is often necessary to hold a second primary in which only the two leading candidates are considered (see act of the 22nd of December 1888, and *ex parte* Sanders, 53 S.C. 478). South Carolina is the only state in which divorce is not allowed in any circumstances; this is a constitutional provision. Divorces were not permitted before 1868 and the provisions of the constitution of that year and of an act of 1872, permitting divorce (for adultery or for wilful desertions for two years) were repealed in 1878. A married woman may hold, acquire and dispose of property as if she were single, and the descent of the estate of a husband dying intestate is the same as that of a wife dying intestate, the survivor being entitled to one-third of the estate if there are one or more children, and to one-half of the estate if there are no children or other lineal descendants. Tenancy by courtesy was abolished in 1883, but the right of dower still obtains; the widow's acceptance of a distributive share in her husband's estate, however, bars her dower. A homestead in lands to the value of $1000, the products of the same, and personal property to the value of $500 which belong to the head of a family or to the husband and wife jointly are exempt from attachment, levy or sale except for taxes, purchase money or debts contracted in making improvements or repairs. The exemption of the homestead continues for the benefit of the widow or for the children alone, whether minors or not, provided it is occupied by some of them, and it may be partitioned among the children regardless of debts. The number of hours' labour for operatives and employés in cotton and woollen mills is limited to sixty a week and must not exceed eleven in any one day, except for making up lost time to the extent of sixty hours in any one year. A prohibition bill introduced in the legislature of 1892 was, through the influence of the Tillman Reform faction, replaced by a substitute measure, which established a dispensary system, based upon the Gothenburg plan. This system went into effect in July 1893 and was in force for thirteen years. Under it the state bought liquors, graded them in accordance with a chemical analysis, and sold them to consumers in packages of not less than one half-pint; the dispensaries were open from sunrise to sunset, no sales were made to minors or drunkards, and no liquor was drunk on the premises; there was a state dispensary commissioner and a state board of control; and the profits were divided between the state, the counties and the municipalities, the share of the state being devoted to educational purposes. The state dispensary was opposed by the old conservative faction, by the saloon keepers, and by the radical prohibitionists. The Supreme Court of the state by a vote of two to one decided in April 1894 that the law was unconstitutional, but in October a change in the personnel of the court brought about a reversal. The Supreme Court of the United States held on the 18th of January 1897 that the provisions of the statute forbidding the importation of liquor by anyone except certain state officials were in violation of the interstate commerce clause of the constitution (*Scott* v. *Donald*, 165 U.S. 58). Under the Brice bill, passed in 1904 and amended in 1905, which gave the people of each county the choice between dispensary and prohibition, with the proviso that if they adopt the latter they must pay the extra taxes necessary to enforce it, several counties adopted prohibition; and in 1907 the state dispensary system was abolished, all impure liquors were declared contraband, each county was required to vote to prohibit the sale of liquors or to establish a dispensary, the sale of intoxicating liquors was forbidden outside of cities and towns, and sales may be made only through county dispensaries, which may not sell at night or on Sunday, or to inebriates or minors. The constitution of 1895 forbade a restoration of the saloon system in its original form. An act of 1909 made it a misdemeanour to solicit orders for liquor in the state.

Education.—As early as 1710 public school education was provided for indigent children. The present free-school system was established in 1868. The educational system is under the supervision of the state superintendent of education, with the assistance of a board composed of the governor and not exceeding seven other persons appointed by the governor. The constitution of 1895 ordered a three-mills levy. The present high-school system dates from an act of 1907; and in 1909–1910 there were 131 high schools, six of which required a full four-years' course. The per capita expenditure according to enrolment was $4·98 for each white pupil and $1·42 for each negro pupil in 1899; in 1909 it was $10·34 for each white pupil and $1·70 for each negro. The schools are supported by taxation; they formerly received the profits from the dispensary. The maximum local tax levy is eight-mills for elementary schools and two-mills for high schools. In 1908–1909 the total expenditures for 5066 public schools (2712 for whites, 2354 for negroes) in the state was $1,898,886, of which $1,590,733 was for whites. The average yearly salary in 1908–1909 in white schools was $479·79 for men and $249·13 for women teachers; in negro schools the corresponding salaries were $118·17 and $91·45. The state supports wholly or in part, the university of South Carolina (before 1906 South Carolina College), established at Columbia in 1801; the South Carolina Military Academy (locally called "The Citadel") established at Charleston in 1845, Clemson Agricultural College (1889), at Clemson, Oconee county, with departments of agriculture, chemistry, mechanics and electricity, textiles and military, and academic and preparatory courses; Winthrop Normal and Industrial College for Girls (1895) at Rock Hill, and the Coloured Normal, Industrial, Agricultural and Mechanical College (1896) at Orangeburg. Among the other higher institutions of learning are the college of Charleston (1790, non-sectarian), Newberry College (1858, Lutheran) at Newberry, the Presbyterian College of South Carolina (1880) at Clinton, Erskine College (1839, Associate Reformed Presbyterian) at Due West, Furman University (1852, Baptist) at Greenville, and Wofford College (1854, Methodist Episcopal South) at Spartanburg; for women, Converse College (1890, non-sectarian) at Spartanburg, the College for Women (1890, Presbyterian) at Columbia, Columbia College (1859, non-sectarian) near Columbia, Greenville Female College (1854, Baptist) at Greenville, Lander Female College (1872, until 1903 at Williamston, and until 1904 the Williamston Female College, Methodist Episcopal South) at Greenwood, and the Due West Female College (1859, Associate Reformed Presbyterian) at Due West; and for negroes, Claflin University (1869, Methodist Episcopal) at Orangeburg, Allen University (1881, African Methodist Episcopal) at Columbia, and several normal and industrial schools. There are theological seminaries at Columbia (1828, Presbyterian), at Due West (1837, Associate Reformed Presbyterian), and at Mount Pleasant (1898, Lutheran).

Charities, &c.—The state has no board of public charities, and under the present constitution the county commissioners are overseers of the poor, except in Charleston and Columbia whose poor are provided for by the municipal authorities. The county commissioners of each county have charge of the poor-house of the county, appoint its superintendent, physician and other officials, and report annually to the judge of the Court of General Sessions, who submits this report to the grand jury. Each poor-house must have sufficient tillable land to give employment to all paupers who are able to work. There is an institution for the deaf, dumb and blind (1849, since 1857 a state institution) at Cedar Springs, and a state hospital for the insane, founded in 1821 at Columbia by Samuel Farrow (1760–1824) and opened in 1828. The state penitentiary is also at Columbia.

Finance.—The revenues of the state are derived mainly from the general property tax, fees, licences, dispensary profits and phosphate royalties. At the beginning of the Civil War the public debt was $3,814,862·91 and the credit of the state was sound. The obligations contracted in support of the war, amounting to about $3,000,000 were of course nullified by the Fourteenth Amendment. There were so many irregularities and so much corruption connected with the bond issues of reconstruction days that it is impossible to discover their exact amount. Estimates of the total debt in 1872 vary from $28,000,000 to $33,000,000. The first step towards repudiation was taken by the "carpet-bag" legislature of 1873, when it provided for the issue of consolidated bonds to replace the outstanding obligations at the rate of fifty cents on the dollar. Nearly six million dollars worth were declared null and void because issued without authority of law. After the return of the Democrats to power in 1877 a further investigation was made and the government finally assumed responsibility for $6,406,606. The greater part of this was funded under an act of October 1892, and provision was made for a sinking fund, derived mainly from the royalty on phosphate beds. In 1909 the funded debt amounted to $6,526,885. The legislature is forbidden to create any further debt except for the ordinary current business of the state, unless the proposition be submitted to the voters of the state and approved by a two-thirds majority. After the abolition of the state dispensary system in 1907 a State Dispensary Commission was created for winding up the business of the dispensary and distributing about $900,000 (of which $100,000 was still due) of dispensary funds. Two companies brought suit for moneys owed for liquor sold to the state dispensary; the commission resisted the suit on the ground that as a court and as a representative of the state it could not be sued; the circuit court and the circuit court of appeals overruled this plea and put the funds into the hands of a receiver; but in April 1909 this famous cause was closed by the decision of the Federal Supreme Court, upholding the commission and restoring to it the fund. Banks are subject to the supervision of an examiner and in addition are required to make weekly reports to the comptroller-general.

History.—The history of South Carolina may be divided into four main periods: the period of discovery and exploration (1520–1663); the period of proprietary rule (1663–1719); the period of royal rule (1719–1776); and the period of statehood (from 1776). The first Europeans to visit the coast were a party of Spaniards from Cuba in 1520. In 1562 some French Protestants under Jean Ribaut made an unsuccessful attempt to establish a colony near the mouth of the Broad river (see PORT ROYAL). In 1629, Charles I. granted to his attorney-general, Sir Robert Heath, all the territory lying between the 31st and the 36th parallels and extending through from sea to sea, but no settlement was made, and in 1663 the same territory was granted to the earl of Clarendon (1609–1674), and six other favourites of Charles II. A second charter in 1665 extended the limits to 29° and 36° 30′. The proprietors were to legislate for the colony "by and with the advice, assent and approbation of the freemen." They were empowered, though not required, to grant religious freedom to Dissenters. Land was held in free and common socage, and the statute *quia emptores* was suspended, thus allowing subinfeudation. Concessions or immigration circulars were issued in 1663 and 1665 offering most liberal terms to prospective colonists. This policy was soon abandoned. In the Fundamental Constitution, adopted by the proprietary board in 1669 John Locke and Lord Ashley (1621–1683) prepared for the colony an elaborate feudal system of government which would have been obsolete even in Europe (see NORTH CAROLINA). Subsequent issues in 1670, 1682 (Jan. 12), 1682 (Aug. 17), and 1698 modified the original plan to some extent. The constitutions possess more than a mere antiquarian interest. They helped to arouse that feeling of discontent among the colonists which culminated in the overthrow of proprietary rule, and they encouraged the large plantation system which constituted the foundation of the slave-holding aristocracy.

The first permanent English settlement was made in April 1670 at Albemarle Point, on the west bank of the Ashley river, but as the situation proved unfavourable the government and most of the people moved over in 1680 to the neck between the Ashley and the Cooper rivers, the site of the present city of Charleston. The area of settlement was gradually extended along the coast in both directions, but did not penetrate far into the interior. The province was soon divided into three coast counties: Berkeley, extending from the Stono river to the Sewee and including Charleston; Craven to the north of the Sewee; and Colleton to the south of the Stono. In addition to those settlers who came direct from England there were many Englishmen from Barbadoes and French Protestants, both of which classes exercised considerable influence upon the history of the colony. It was largely due to the Barbadian connexion that South Carolina was for many years more closely associated with the island than with the continental colonies. Her political history during the colonial era is the story of a struggle between popular and prerogative interests, first between the people and the lords proprietors, later between the people and the Crown. From 1670 to 1700 the principal questions at issue were the refusal of the settlers to subscribe to the numerous editions of the Fundamental Constitutions and disputes over the collection of quit-rents. Concessions were finally made which brought the government more directly under popular control. In 1692 the legislature was divided into two houses, and in 1693 the commons house, elected by the people, secured the privilege of initiating legislation. The truce was followed by a controversy between Churchmen and Dissenters. A test act requiring members of the assembly to conform to the Church of England and to take the sacrament of the Eucharist according to the rites and usages of that Church (1704) was defeated only through the intervention of the Whig House of Lords in England. By an act of the 30th of November 1706, which remained in force until the War of American Independence, the Church of England was made the established religion. After a few years of peace and prosperity there came another attack upon the proprietors which culminated in the revolution of 1719 and the downfall of proprietary rule. Acting on the advice of Chief Justice Nicholas Trott (1663–1740) the proprietors adopted a reactionary policy, vetoed several popular laws, and refused to afford protection from the attacks of the Indians. The people rebelled, overthrew the existing government and elected their leader James Moore (1667–1723) as governor. The result of the revolution was accepted in England, and the colony at once came under royal control, although the rights of the proprietors were not extinguished by purchase until 1729. Theoretically South Carolina and North Carolina constituted a single province, but, as the settlements were far apart, there were always separate local governments. Until 1691 each had its own governors, from 1691 to 1712 there was usually a governor at Charleston and a deputy for the northern settlements, and after 1712 there were again separate governors. The first attempt to define the boundary was made in 1732, but the work was not completed until 1815.

The change from proprietary to royal government scarcely affected at all the constitutional development of the province. The popular branch of the assembly continued to encroach upon the powers of the governor and council. By 1760 the council had almost ceased to exercise any real control over legislation. They rarely initiated or amended a bill of any kind, never a revenue measure. Public officials chosen nominally by the General Assembly were really the nominees of the lower house. In the conduct of his executive functions the governor found himself constantly hampered by committees of the Assembly. In other words, whether they were conscious of the fact or not, the South Carolinians throughout the colonial era were tending towards independence. The demands of the British government after 1760 were not especially unreasonable or tyrannical, but they were made upon a people who were too long accustomed to having their own way. As the spirit of rebellion developed the sentiment in favour of colonial union gained in strength. Thomas Lynch (*c.* 1720–1776), Christopher Gadsden (1724–1805), and John Rutledge (1739–1800) attended the Stamp Act Congress of 1765, an intercolonial committee of correspondence was appointed in 1773, and delegates were sent to the Continental Congress in 1774 and 1775. A council of safety appointed by a Provincial Congress practically took charge of the government in June 1775. The Assembly was formally dissolved on the 15th of September, Governor William Campbell (d. 1778) fled from the town, and royal government came to an end. In the conflict with the mother country the people had the advantage of long experience in fighting. There had been wars with the Spanish in 1686, 1702–04, 1740, with the Spanish and French in 1706, with pirates in 1718, with the Yemassee Indians in 1715 and the Cherokees in 1760–61, and a slave uprising in 1739. The state suffered severely during the War of Independence, the numbers and influence of the Loyalists serving to embitter the conflict. In the summer of 1776 the British, under Sir Henry Clinton and Sir Peter Parker attempted to capture Charleston and summon the South Carolina Loyalists to their standard, but on the 28th of June the fleet was repulsed in an assault on Fort Moultrie. Clinton returned, however, early in 1780, and, as he surrounded the city on all sides with an overwhelming force, General Benjamin Lincoln, who was defending it with about 7000 men, surrendered (May 12) to avoid certain destruction. The British thereupon overran the whole state, and until near the close of the war a new American army, first under Horatio Gates and later under Nathanael Greene, was engaged in driving them out. The principal engagements fought within the state were Camden (Aug. 16, 1780), King's Mountain (Oct. 7, 1780), Hobkirk's Hill (April 25, 1781), and Eutaw Springs (Sept. 8, 1781).

The most significant feature in the early history of the state was the struggle between the Low Country, which centred about Charleston, and the Up Country, which was settled largely by Scotch-Irish, who came down the mountain valleys from North Carolina, Virginia and Pennsylvania. The great planters of the low country had wealth, the small farmers of the up country had numbers. Under the first state constitution, adopted in March 1776, the low country element maintained the ascendancy which they had possessed during the colonial period. In 1786 they were forced to consent to the removal of the seat of government to Columbia (final removal, 1790) and in 1808 to a reapportionment of the representation, based partly on wealth and partly on numbers. There was to be one representative for every sixty-second part of the whole number of white inhabitants of the state and one for every sixty-second part of the taxes raised by the legislature. More harmonious relations were in time established, partly because of improvements in the methods of transport, but mainly as a result of outside pressure in the form of criticism of slavery and the adoption by the national government of an economic policy which favoured the manufacturers at the expense of the agricultural interests. In 1832 there was a majority from each section in favour of Nullification (*q.v.*), and the legislature called the famous Nullification Convention, which met at Charleston the 19th of November, and five days later passed the Ordinance of Nullification declaring that certain acts of Congress imposing import duties "are unauthorized by the Constitution of the United States and violate the true meaning and intent thereof, and are null and void and no law, nor binding upon this state, its officers or citizens." President Jackson was ready to use force against the state; and the tariff, over which the whole disagreement had arisen, was changed in such a way as to effect a compromise with the state. From about 1828 to 1861 South Carolina superseded Virginia as the leader of the South. She stood for states' rights and free trade. John C. Calhoun was her political philosopher and George McDuffie her political economist. Her secession, on the 20th of December 1860, was followed by the formation of the Southern Confederacy, the bombardment of Fort Sumter (April 12, 1861) and the Civil War (1861–65). Although few battles were fought within her limits, because of the distance from the frontier, South Carolina made many sacrifices in the interest of her section. With a white population of 291,300 at the beginning of the conflict, the state put into the field during the four years 62,838 effective men, with an enrolment, including reserves, of 71,083, of whom 22% were killed on the field or died in prison. General W. T. Sherman's march across the state (February–March, 1865) was accomplished by an enormous destruction of property by fire and pillage.

All the misfortunes of the war itself are insignificant when compared with the sufferings of the people during the era of Reconstruction (1865–1871). In accordance with the liberal views of President Andrew Johnson, the white people assumed control of affairs shortly after the close of hostilities, and James L. Orr (1822–1873) was chosen governor. Congress reversed this policy (1867), disfranchised the majority of the whites and transferred political power to negroes, Northern adventurers and disreputable native whites. There followed an orgy of crime and corruption. The Assembly Hall was furnished with clocks costing $600 dollars each, sofas at $200, and other articles in proportion. A restaurant and bar were kept in the State House at which the members of the legislature and their friends could procure refreshments free of cost. The debt of the state was increased from $5,000,000 in 1868 to more than $18,000,000 in 1872. Crime among the negroes became so frequent that the whites were compelled to form a secret organization for protection (see KU KLUX KLAN). In the spring of 1868 the state adopted a new constitution in conformity with the Reconstruction Acts of Congress, and elected state officers and congressmen, and on the 25th of June the state was readmitted to the Union. The inauguration of General Wade Hampton (1818–1902) as governor, and the final withdrawal of United States troops in 1877, marked the downfall of negro rule.

The political history of the state since 1877 presents some interesting features. Practically the entire white population is Democratic, partly for historical reasons and partly because of a feeling that union is necessary to maintain white supremacy. The old warfare between the Up Country and the Low Country has been renewed in a modified form in the conflict between Reformers and Conservatives. The triumph of the Reformers culminated in the founding of Clemson Agricultural College (1889), the establishment of the state dispensary system for the sale of intoxicating liquors (1893), the election of Benjamin R. Tillman (b. 1847) to the United States Senate (1894) over M. C. Butler (1836–1909), and the work of the constitutional convention of 1895.

Governors of South Carolina

Proprietary Period (1670–1719)

William Sayle		1670–1671
Joseph West	(chosen by the council)	1671–1672
Sir John Yeamans		1672–1674
Joseph West		1674–1682
Joseph Morton		1682–1684
Richard Kyrle		1684
Robert Quarry	(chosen by the council)	1684–1685
Joseph West		1685
Joseph Morton		1685–1686
James Colleton		1686–1690
Seth Sothell		1690–1692
Philip Ludwell		1692–1693
Thomas Smith		1693–1694
Joseph Blake	(chosen by the council)	1694
John Archdale		1694–1696
Joseph Blake		1696–1700
James Moore	(chosen by the council)	1700–1702
Sir Nathaniel Johnson		1702–1710
Edward Tynte		1710
Robert Gibbes	(chosen by the council)	1710–1711
Charles Craven		1711–1716
Robert Daniel	(deputy-governor)	1716–1717
Robert Johnson		1717–1719

Royal Period (1719–1776)

James Moore	(elected by the people)	1719–1721
Sir Francis Nicholson		1721–1729
Arthur Middleton	(president of the council and acting-governor)	1724–1729
Robert Johnson		1729–1735
Thomas Broughton	(lieutenant-governor)	1735–1737
William Bull	(president of the council, lieutenant-governor)	1737–1743
James Glen		1743–1756
William Henry Lyttleton		1756–1760
William Bull, the 2nd	(lieutenant-governor)	1760–1761
Thomas Boone		1761–1764
William Bull, the 2nd	(lieutenant-governor)	1764–1766
Lord Charles Greville Montague		1766–1768
William Bull, the 2nd	(lieutenant-governor)	1768
Lord Charles Greville Montague		1768–1769
William Bull, the 2nd	(lieutenant-governor)	1769–1771
Lord Charles Greville Montague		1771–1773
William Bull, the 2nd	(lieutenant-governor)	1773–1775
Lord William Campbell		1775
Henry Laurens	(president of the council of safety)	1775–1776

Statehood Period (1776–)

John Rutledge	(president)	1776–1778
Rawlins Lowndes	(president)	1778–1779
John Rutledge		1779–1782
John Matthewes		1782–1783
Benjamin Guerard		1783–1785
William Moultrie		1785–1787
Thomas Pinckney		1787–1789
Charles Pinckney	Democrat-Republican	1789–1792
William Moultrie	„	1792–1794
Arnoldus Vanderhorst	„	1794–1796
Charles Pinckney	„	1796–1798
Edward Rutledge	„	1798–1800
John Drayton	„	1800–1802
James B. Richardson	„	1802–1804
Paul Hamilton	„	1804–1806
Charles Pinckney	„	1806–1808
John Drayton	„	1808–1810
Henry Middleton	„	1810–1812
Joseph Alston	„	1812–1814
David R. Williams	Democrat-Republican	1814–1816
Andrew Pickens	„	1816–1818
John Geddes	„	1818–1820
Thomas Bennett	„	1820–1822
John L. Wilson	„	1822–1824
Richard I. Manning	„	1824–1826
John Taylor	„	1826–1828
Stephen D. Miller	Democrat	1828–1830
James Hamilton, jun.	„	1830–1832
Robert Y. Hayne	„	1832–1834
George McDuffie	„	1834–1836
Pierce M. Butler	„	1836–1838
Patrick Noble	„	1838–1840
B. K. Henegan	„ (acting)	1840
John P. Richardson	„	1840–1842
James H. Hammond	„	1842–1844
William Aiken	„	1844–1846
David Johnson	„	1846–1848
Whitemarsh B. Seabrook	„	1848–1850
John H. Means	„	1850–1852
John L. Manning	„	1852–1854
James H. Adams	„	1854–1856
Robert F. W. Allston	„	1856–1858
William H. Gist	„	1858–1860
Francis W. Pickens	„	1860–1862
Milledge L. Bonham	„	1862–1864
Andrew G. McGrath	„	1864–1865
Benjamin F. Perry	„ (provisional)	1865
James L. Orr	Conservative	1865–1868
Gen. Edward R. S. Canby	(military governor)	1868–
Robert K. Scott	Republican	1868–1872
Franklin J. Moses, jun.	„	1872–1874
Daniel H. Chamberlain	„	1874–1876
Wade Hampton	Democrat	1876–1879
William D. Simpson	„ (acting)	1879–1880
Thomas D. Jeter	„ (acting)	1880
Johnson Hagood	„	1880–1882
Hugh S. Thompson	„	1882–1886
John C. Sheppard	„ (acting)	1886
John P. Richardson	„	1886–1890
Benjamin R. Tillman	„	1890–1894
John G. Evans	„	1894–1897
William H. Ellerbe	„	1897–1899
Miles B. McSweeney	„	1899–1903
Duncan C. Heyward	„	1903–1907
Martin F. Ansel	„	1907–1911
Coleman L. Blease	„	1911–

Bibliography—For general description see Michael Tuomey, *Report on the Geology of South Carolina* (Columbia, 1848); the *Handbook of South Carolina*; *Resources, Institutions, and Industries of the State*, published by the State Department of Agriculture, Commerce and Immigration (Columbia, 1907; 2nd ed., 1908); the *Annual Reports* (1904 seq.) of the same department and its other publications; and W. G. Simms, *Geography of South Carolina* (Charleston, 1843). For administration see D. D. Wallace, *The Civil Government of South Carolina* (Dallas, 1906); E. L. Whitney, *Government of the Colony of South Carolina*, in Johns Hopkins University Studies, vol. xiii. (Baltimore, 1895); B. J. Ramage, *Local Government and Free Schools in South Carolina*, in Johns Hopkins University Studies, vol. i. No. 12 (Baltimore, 1883); Colyer Meriwether, *History of Higher Education in South Carolina* (Washington, 1889), in Circulars of Information of the United States Bureau of Education, No. 3. There is no general history of South Carolina. The standard work for the colonial period is Edward McCrady's *The History of South Carolina under the Proprietary Government, 1670–1719* (New York, 1897) and his *History of South Carolina under the Royal Government, 1719–1776* (ibid. 1899), which are accurate and interesting, but neglect the manuscript sources at Columbia. Older histories are Alexander Hewatt, *Historical Account of the Rise and Progress of the Colonies of South Carolina and Georgia* (London, 1779), freely used by later writers; David Ramsay, *History of South Carolina* (2 vols., Charleston, 1809), little more than a reprint, without acknowledgments, of Hewatt; and William J. Rivers, *Sketch of the History of South Carolina to the Close of the Proprietary Government, 1719* (Charleston, 1856), which was utilized by McCrady in his first volume and was the first history of the colony based on the documents in the Public Records Office. See also E. L. Whitney, "Bibliography of the Colonial History of South Carolina," in *Annual Report of the American Historical Association for the Year 1894* (Washington, 1895). More distinctly legal and political in character are three doctors' monographs: Edson L. Whitney, *Government of the Colony of South Carolina* (Baltimore, 1895), based too exclusively on the statutes; D. D. Wallace, *Constitutional History of South Carolina from 1725 to 1775* (Abbeville, S. C., 1899; new ed., 1908), a very brief summary; and W. Roy Smith, *South Carolina as a Royal Province, 1719–1776* (New York, 1903), based on the manuscript sources at Columbia. The standard work for the War of Independence is Edward McCrady, *The History*

of South Carolina in the Revolution, 1776–1783 (2 vols., New York, 1901–1902). Older books on the subject are David Ramsay, *History of the Revolution of South Carolina from a British Colony to an Independent State* (2 vols., Trenton, 1785); William Moultrie, *Memoirs of the American Revolution, so far as it related to the States of North and South Carolina and Georgia* (2 vols., New York, 1802); John Drayton, *Memoirs of the American Revolution relating to the State of South Carolina* (2 vols., Charleston, 1821); and R. W. Gibbes, *Documentary History of the American Revolution* (3 vols., Columbia, 1853; New York, 1857). Very little has been written on the period since 1783. David F. Houston, *Critical Study of Nullification in South Carolina* (New York, 1896), is a concise, scholarly work. Hermann von Holst's *John C. Calhoun* (Boston, 1892), is written from the extreme nationalistic and anti-slavery point of view. For the Civil War and Reconstruction, see James Ford Rhodes, *History of the United States from the Compromise of 1850* (5 vols., New York, 1893–1904); James S. Pike, *The Prostrate State; or South Carolina under Negro Government* (New York, 1874); Carl Schurz, *Report on the States of South Carolina, Georgia*, &c. (Washington, 1865, being 39th Congress, 1st session, Sen. Ex. Doc. 2); Hilary A. Herbert and others, *Why the Solid South?* (Baltimore, 1890); and John P. Hollis, *The Early Period of Reconstruction in South Carolina* (Baltimore, 1905), containing an excellent discussion of the period from 1865 to 1868. For the religious history see Frederick Dalcho, *An Historical Account of the Protestant Episcopal Church in South Carolina from the first Settlement of the Province to the War of the Revolution* (Charleston, 1820); G. D. Bernheim, *History of the German Settlements and of the Lutheran Church in North and South Carolina* (Philadelphia, 1872). An excellent monograph on the controversy between the Up Country and the Low Country is William A. Schaper, *Sectionalism and Representation in South Carolina* (Washington, 1901). Among the chief printed sources are the *North Carolina Colonial Records* (10 vols., Raleigh, 1886–1890), useful for the early period; B. R. Carroll, *Historical Collections of South Carolina* (2 vols., New York, 1836); and the *South Carolina Historical Society Collections* (5 vols., Charleston, 1857, 1858, 1859, 1887 and 1897—vol. v. contains the Shaftesbury Papers).

SOUTHCOTT, JOANNA (1750–1814), English religious fanatic, was born at Gittisham in Devonshire. Her father was a farmer and she herself was for a considerable time a domestic servant. She was originally a Methodist, but about 1792, becoming persuaded that she possessed supernatural gifts, she wrote and dictated prophecies in rhyme, and then announced herself as the woman spoken of in Rev. xii. Coming to London at the request of William Sharp (1749–1824), the engraver, she began to "seal" the 144,000 elect at a charge varying from twelve shillings to a guinea. When over sixty she affirmed that she would be delivered of Shiloh on the 19th of October 1814, but Shiloh failed to appear, and it was given out that she was in a trance. She died of brain disease on the 29th of the same month. Her followers are said to have numbered over 100,000, and only became extinct at the end of the 19th century.

Among her sixty publications, all equally incoherent in thought and grammar, may be mentioned: *Strange Effects of Faith* (1801–1802), *Free Exposition of the Bible* (1804), *The Book of Wonders* (1813–1814), and *Prophecies announcing the Birth of the Prince of Peace* (1814). A lady named Essam left large sums of money for printing and publishing the *Sacred Writings of Joanna Southcott*. The will was disputed by a niece on the ground that the writings were blasphemous, but the court of chancery sustained it.

See D. Roberts, *Observations on the Divine Mission of Joanna Southcott* (1807); R. Reece, *Correct Statement of the Circumstances attending the Death of Joanna Southcott* (1815).

SOUTH DAKOTA, one of the North Central states of the American Union, lying between 42° 28′ and 45° 57′ N. Lat. and 96° 26′ and 104° 3′ W. long. It is bounded N. by North Dakota; E. by Minnesota and Iowa; S. by Nebraska; and W. by Wyoming and Montana. Lake Traverse and the Big Stone Lake separate the state in part from Minnesota; the Big Sioux River forms most of the boundary between South Dakota and Iowa; and the Missouri river separates the state in part from Nebraska. South Dakota has an extreme length, east and west, of 380 m., an extreme width, north and south, of 245 m., and a total area of 77,615 sq. m., of which 747 sq. m. are water-surface.

Topography.—With the exception of the Black Hills district in the south-west, the state is a wide rolling plain, with its eastern portion a part of the Prairie Plains region, and its western portion a part of the Great Plains. The surface of this plain, however, ranges from level river valleys in the east to irregular plateaus broken by buttes and scored by cañons in the west. The lowest part of the state is the surface of Big Stone Lake, about 970 ft. above the sea; the highest point is Harney Peak in the Black Hills, which rises to a height of 7216 ft. The state as a whole has a mean elevation of 2200 ft., with 270 sq. m. below 1000 ft.; 42,300 sq. m. between 1000 and 2000 ft.; 23,000 sq. m. between 2000 and 3000 ft.; 10,700 sq. m. between 3000 and 5000 ft.; and 1380 sq. m. between 5000 and 8000 ft.

In the extreme north-east there is a range of low hills known as the Coteau des Prairies, which crosses the state in a S.S.E. direction through Marshall, Roberts, Grant and Deuel counties and maintains an almost constant altitude of from 1950 to 2050 ft. It forms the divide between the headwaters of the Minnesota river on the east and of the James river on the west. To the south and west of the Coteau des Prairies lie vast stretches of plains, including the valleys of the Big Sioux and James rivers. This region presents no striking topographic features except the numerous small lakes which occupy the hollows created by the continental ice-sheet. The greater part of the James River Valley lies in the bed of the extinct Lake Dakota, which was once a very narrow body of water extending northward from about the latitude of the present town of Mitchell for a short distance into what is now North Dakota. West of the James River Valley lies an elevated table-land, known as the Coteau du Missouri, which marks the water-parting between the James and the Missouri rivers, and has a general elevation of about 1800 ft. Along the west boundary of the state the general elevation of the Great Plains is about 3500 ft. As the part east of the river was once covered by the ice-sheet, its hills have been lowered and its valleys filled through the attrition of glaciers until the surface has a gently undulating appearance. West of the Missouri river the sheet of glacial drift is absent, and the lands everywhere show evidence of extensive stream erosion. The surface is broken by many clusters of small hills, such as the Fox Ridge in the central part of the state and the Cave Hills in the north-west, and in the vicinity of streams it is much cut up by deep ravines. In the south-west the results of this erosion are seen in an accentuated form in the region between the White river and the South Fork of the Cheyenne river, known as the Bad Lands or *terres mauvaises*. This area extends from the 101st meridian up the White river for about 120 m. and varies in width from 30 to 50 m. Here the land surface has been carved into forms in infinite variety. Many slender columns of clay, supporting masses of sandstone which have protected them from erosion, rise from the surface like gigantic toadstools. The sides of these ridges and pinnacles are bare of vegetation and display a variety of colours in buff, cream, pale green, grey and flesh. The most prominent features of the landscape rise from 150 to 300 ft. above the valleys; the latter and the flat tops of the mesas are sometimes covered with a scanty soil and a sparse growth of grass. These Bad Lands were once a fairly level plain, but intricate stream erosion produced the labyrinth of ravines and ridges for which the region is noted. The Bad Lands of the White river are also noted for their wealth of animal fossils, which have been found in such quantities as to cause geologists to believe that the vertebrates perished there in droves during a severe storm or flood. Other Bad Lands, on a less impressive scale, are found along the Grand and the Moreau or Owl rivers. North-west of the Bad Lands of the White river lie the Black Hills (*q.v.*), an irregular dome-shaped uplift, about 125 m. long and 60 m. wide, lying partly in Wyoming, and with the main axis trending almost north-west and south-east. The uplift is completely enclosed by a rim of hog-back ridges from 300 to 600 ft. above the plain, and between this rim and the hills proper lies the Red Valley, a tract about 3 m. wide and bordered on the inner side by the main mass of limestone and crystalline rocks which have in general a height of 4000 or 5000 ft. above the sea—some ridges and peaks rise higher still. Upon this limestone plateau there is a central area of high ridges, among them the rough crags of Harney, Custer and Dodge peaks. Between the ridges of the central area lie wide valleys and "parks." The streams flowing from the central area have cut deep gorges and cañons, and among the ridges the granitic rocks have assumed many strange forms. Though rising from a semi-arid plateau, these mountains have sufficient rainfall to support an abundant plant growth, and have derived their name from the fact that their slopes are dark with heavy forests. Cathedral Park in the southern portion, Spearfish Cañon in the north, and the extensive fossil forest at the foot of Mattie's Peak are noteworthy; while the Crystal Cave, near Piedmont, and the Wind Cave, near Hot Springs, are almost unrivalled.

With the exception of the extreme north-east, the state lies within the drainage system of the Missouri river. This stream enters the state near the centre of the northern boundary, pursues a winding south-easterly course, and from its intersection with the 43rd parallel of N. lat. to its junction with the Big Sioux river separates South Dakota from Nebraska. The Big Sioux river rises in the Coteau des Prairies in the north-east and flows almost directly south for nearly 200 m., in the lower part of its course forming

the boundary between South Dakota and Iowa. To the west of this stream and almost parallel with it is the James or Dakota river, which rises in North Dakota and follows a general course southward until it joins the Missouri river near Yankton. From the west the Missouri receives the Grand, Moreau or Owl, Cheyenne and White rivers. Of these the Cheyenne is the most important, being formed by two branches, the Belle Fourche and the South Fork, which, after almost completely encircling the Black Hills, unite at a point nearly 350 m. from their sources. Many of the smaller streams in the Black Hills lose their waters in their lower courses through seepage and evaporation. The Minnesota river has its source in the north-east, and the Big Stone Lake, a body of water about 25 m. long and 3 m. wide, forms a connecting link between its headwaters and the rest of the stream. North of this lake lies Lake Traverse, 27 m. long and 3 m. wide, whose waters flow north into the Bois de Sioux river, whence they flow into the Red River (of the North). The portion of South Dakota east of the Missouri river is dotted with numerous lakes, ranging from small ponds to bodies of water from 10 to 15 m. in diameter. The plains, except in the south-east corner, are underlaid by sheets of water-bearing sandstone, which carry a volume of water under such pressure that in the valleys of the James river and the Missouri river and its western tributaries a strong surface flow may be obtained from artesian wells. In 1905 over a thousand wells had been sunk east of the Missouri, and the flow was estimated at 7,000,000 gallons per day.

Fauna and Flora.—Large game within the state is practically extinct. The herds of bison, antelope and elk that once roamed the prairies have vanished, but a few mountain sheep still graze on the grass-covered mesas in inaccessible portions of the Bad Lands. There, too, the grey (or timber) wolf and the coyote are found. The species of small animals do not differ from those found in other parts of the Middle West.

The total woodland area has been estimated at 2500 sq. m., about 3·25% of the land area, and of this amount 2000 sq. m. are in the Black Hills district. All the higher lands of this area are covered by forests; but the Red Valley, lying between the outer ridges and the main uplift, is treeless. Most of the forest consists of yellow pine, but the spruce, aspen, white birch, bur oak, box elder, red cedar, white elm and cottonwood are among the other varieties found. With the exception of narrow strips of woodland along the courses of the larger streams, the rest of the state consists of treeless prairie-lands, which are usually covered with valuable grasses. In the more arid regions the sage-brush and cactus make their appearance. Two national forests contained (1910) 2022 sq. m.

Climate.—The climate of South Dakota is of a continental type. Owing to the northern latitude, comparatively high altitudes, and the great distance from the ocean, there are great annual variations of temperature and a very small amount of rainfall. The state is coldest in the north-east and warmest in the region south of the Cheyenne and west of the Missouri river. The isothermal lines trend from south-east to north-west. The winters are long and marked by exceedingly low temperatures, but as they are the driest season of the year, the extremes are not so disagreeable as they would be in a more humid region. The mean winter temperature ranges from 13° F. at Aberdeen in the northern part of the James River Valley to 25° at Rapid City, in the Black Hills district. The absolute minima at these two places are respectively −46° and −29°; the absolute maxima, 111° and 106°, and the mean annual temperatures, 42° and 46°. At Brookings, in the extreme east, the mean annual temperature is 43°; the mean for the summer is 68° with an extreme recorded of 104°; the mean for the winter is 15° with an extreme recorded of −41°. At Ashcroft, in the extreme north-west, the mean annual temperature is 44°; the mean for the summer 68°; and for the winter 20°; while the highest and lowest temperatures ever recorded are respectively 114° and 44°.

The average annual amount of rainfall for the state is about 20 in., ranging from 13·9 in. at Ashcroft to 25·9 in. at Aberdeen. It is usually greatest in the valleys of the James and Big Sioux rivers and least in the extreme north-central and north-western parts of the state. The average amount of rainfall for the spring is 6 or 7 in.; for the summer, 8 or 9 in.; for the autumn, 3 or 4 in.; and for the winter, 1 or 2 in. The snows are generally light, and cattle may graze on the prairies during most of the winter; but there are occasional severe "blizzards," which are accompanied by intense cold and high winds.

Soils.—The glacial drift east of the Missouri river, unlike that of the New England states, is remarkably free from boulders and gravel, except in a few morainic belts. It is often locally enriched by vegetable mould, and is well adapted for wheat-growing. West of the Missouri river the drift gives place to a fine soil of sand and clay, with deposits of alluvium in the vicinity of streams. Though lacking in vegetable mould, these soils are generally capable of producing good crops where the water-supply is sufficient. The larger valleys of the Black Hills district contain fertile alluvial deposits washed from the neighbouring highlands, but in the plains adjoining these mountains the soils consist of a stiff gumbo suitable only for pasture land. There are throughout the state occasional tracts in which, owing to deficient drainage, an excess of alkali has accumulated, and which require special treatment before they can be made again productive.

Irrigation.—South Dakota in 1889 had only 15,717 acres of irrigated land. Ten years later this area had increased to 43,676 acres. Of the total, 38,453 acres were irrigated by streams and 5,223 acres by wells. The area irrigated by streams was confined largely to the Black Hills region, the water being supplied by the North Fork and the South Fork rivers, which are tributaries of the Cheyenne. The artesian basin of the east part of the state is fairly well developed, several wells having a flow of from 2000 to 4350 gallons per minute and a pressure of 150 ℔ to the square inch. Under the Reclamation Act passed by Congress in 1902 the irrigation of 100,000 acres in the Belle Fourche Valley adjacent to the Black Hills region was provided for. It provides for a dam across Owl Creek 6500 ft. long and 20 ft. wide on top, and for two main canals from this distributing centre, one the north canal supplying water for the irrigation of 66,857 acres north of the Belle Fourche river and east of Owl Creek, and the other the south canal for the irrigation of 28,240 acres south of the Belle Fourche. Lateral canals are provided from the main canals to each farm.

Agriculture.—Agriculture is the leading industry in South Dakota; in 1900 out of 137,156 persons engaged in occupations, 82,857 followed agricultural pursuits. In 1890 the total acreage devoted to farming was 11,396,460, which in 1900 had increased to 19,070,616. The percentage of improved acreage, however, fell during the same period from 61·1% in 1890 to 59·2% in 1900. This was due largely to the opening up of land which had formerly not been utilized. The average size of farms (excluding farms under 3 acres with products valued at less than $500) was 227·2 acres in 1890 and 364·1 acres in 1900. The value of all farm property increased from $145,527,556 in 1890 to $297,525,302 in 1900. The average farm value also rose during these ten years from $2901 to $5654, and the value per acre advanced from $12·77 to $15·60. Fewer farms were worked by owners in 1900 than in 1890, the percentage in the former year being 78·2 and in the latter year 86·6. In 1900 share tenants worked 18·4% of the farms and cash tenants, 3·4%. The total value of farm products in 1899 was $66,082,419 as against $22,047,279 in 1889. Of the total product value in 1899, 78·3% was represented by cereals, South Dakota ranking sixteenth among the states in cereal production. Wheat constituted 60·7% of the total for all cereals, Indian corn 21·1%, oats 11·9% and barley 5·8%. A considerable area was devoted to the cultivation of apples, plums and cherries. The total acreage of spring wheat, the state's leading crop, in 1909 was 3,375,000 with a yield of 47,588,000 bush. valued at $42,829,000, South Dakota ranking third among the states. Next in importance in 1909 came Indian corn with an acreage of 2,059,000 and a product of 65,270,000 bush. ($32,635,000). Oats had an acreage of 1,450,000 and a product of 49,600,000 bush. ($14,790,000). Barley was cultivated on 1,021,000 acres, the product amounting to 19,910,000 bush. ($8,960,000). In the quantity of barley produced the state ranked fifth. In its output of flax, grown almost entirely for the seed, the state held second rank with a product of 5,640,000 bush. ($8,516,000). The hay acreage was 536,000 and the production, 804,000 tons. Wheat grows chiefly in the east and north-east parts of the state, especially in Brown, Spink, Roberts, Day and Grant counties, the largest crop in 1899 being that of Brown county, 3,320,570 bush., or about one-twelfth of the state's product. Corn grows throughout the western half of the state, and especially in the south-western parts, in Lincoln, Clay, Union, Yankton and Bonhommie counties, the largest crop in 1899 being that of Lincoln county, 3,914,840 bush., nearly one-eleventh of the state crop. Oats has a distribution similar to that of corn, the largest crop in 1899 being that of Minnehaha county, 1,666,110 bush., about one-nineteenth of the state crop. Barley grows principally in the eastern and southern parts of the state—Minnehaha, Moody, Lake and Brookings counties—the largest crop in 1899 being that of Minnehaha county, 932,860 bush., more than one-seventh of the state.

The state is especially well adapted for grazing, and during 1890–1900 there was a large increase in the number of farm animals. The gain was chiefly confined to cattle, but the number of horses, sheep and swine also showed substantial increases. The value of all livestock in 1890 was $29,689,509 and in 1900, $65,173,432. The number and value respectively of the various farm animals on the 1st of January 1910 were as follows: horses, 612,000 ($64,260,000), dairy cows, 656,000 ($21,648,000); other cattle, 1,341,000 ($28,832,000); swine, 805,000 ($8,936,000); and sheep, 829,000 ($3,316,000).

Mining.—The minerals of South Dakota, of which gold is the most important, are chiefly found in the Black Hills region. This section covers about 3500 sq. m. in the south-east part of the state and includes the counties of Lawrence, Custer, Meade, Pennington and Fall River. Silver follows gold in importance, but the other minerals met with, including gypsum, mica, petroleum, natural gas, granite, marble and tin are not found in paying quantities.

Gold was first discovered in French Creek, Custer county, on the 27th of July 1874 by miners who were with Custer's expedition. Gold was also found later in Lawrence county north of Custer.

and the Homestake Belt in the former county has ever since been the chief producer in the state. For ten years after the Black Hills were thrown open little gold was mined because of the lack of railway facilities. Cement deposits were discovered in the Black Hills region in 1876 and in the same year the first quartz mill was set up in Deadwood. In 1889 a cement plant was built at Yankton, and it is still worked although the output is small. Mica-mining was also carried on for a time but was soon abandoned. The first natural gas-well in the state was drilled at Pierre in 1892.

The total value of all mineral products in 1902 was $6,769,104, of which $6,464,258 were represented by gold and silver, $110,789 by sandstones and quartzites and $86,605 by limestones and dolomites; in 1908 the total value was $8,528,234, which was an increase of more than $3,500,000 over the value in 1907. This increase was due almost entirely to the gain in the gold output which advanced in value from $4,138,200 in 1907 to $7,742,200 in 1908. The total amount of gold mined in 1908 was 374,529 fine ounces, the greater part coming from the Homestake Mine In 1908, 197,300 oz. of silver were obtained, valued at $105,500 as against $70,400 in 1907 and $101,086 in 1906.

Manufactures.—Manufacturing in South Dakota is of little importance and is confined chiefly to articles for home consumption. Between 1890 and 1900 the number of establishments increased from 499 to 1639, the capital invested from $3,207,796 to $7,578,895, and the value of products from $5,682,748 to $12,231,239. Under the factory system there were 624 establishments in 1900 and 686 in 1905; the capital invested in 1900 was $6,051,288 and in 1905 $7,585,142; and the value of the products was $9,529,946 in 1900 and $13,085,333 in 1905. Both in 1900 and 1905 flour and grist-mill products ranked first in value, the figures for 1900 being $3,208,532 and for 1905 $6,519,364. The second industry was the manufacture of cheese, butter and condensed milk, and the third, printing and publishing. Sioux Falls is the principal industrial centre.

Transportation.—The railway mileage of Dakota in 1870 (before the present states of South and North Dakota were erected) was only 75 m., and in 1880, 1225 m. In 1890 the mileage of South Dakota was 2610 m., in 1900, 2961 m., and in 1909, 3776 m. The principal systems are the Chicago, Milwaukee & St Paul, the Great Northern and the North-western. The principal waterway is the Missouri River, whose channel has an average depth at low water of about 2½ ft. between Sioux City and Fort Benton, Montana, but the constant shifting of the channel makes navigation uncertain.

Population.—The total population of South Dakota in 1890 (the date of the first Federal census taken since its separate existence as a state) was 328,808, and in 1900 it was 401,570; the increase from 1890 to 1900 being (exclusive of persons on Indian reservations) 16·8%. In 1910, according to the U.S. census, the total was 583,888. Of the population in 1900, 380,714 were whites, 88,508 were foreign-born, 465 were negroes, and 20,225 were Indians. Of the Indians 9293 were taxed. The population on Indian reservations in 1890 was 19,792; in 1900, 17,683. The Indians on reservations and in Indian schools include members of the Yankton, Yanktonai, Oglala, Brulé, Sisseton, Wahpeton, Flandreau, Sioux, Blackfeet, Miniconjou, Sans Arc and Ute tribes, on the Standing Rock and Cheyenne River reservations in the north of the state, the Lower Brulé and Crow Creek reservations in the central part, and the Pine Ridge and Rosebud reservations in the south. The figures for inhabitants born in the United States but not within the state show a preponderance of immigration from neighbouring states, there being, in 1900, 31,047 natives of Iowa, 24,995 natives of Wisconsin, 18,565 of Minnesota and 16,145 of Illinois, out of a total of 313,062. Of the total foreign-born population of 88,508, 19,788 were Norwegians, 17,873 Germans, 12,365 Russians, 5906 English Canadians, 5038 Danes, 3862 English and 3298 Irish. Of the total population 245,383 were of foreign parentage—*i.e.* either one or both parents foreign-born—and of those having both father and mother of foreign birth there were 44,516 of German parentage, 44,119 of Norwegian, 25,113 of Russian and 11,222 of Irish parentage. From 1890 to 1900, on the basis of places having 4000 inhabitants or more, the urban population increased from 10,177 in 1890 to 28,743 in 1900; so that there was the remarkable increase of 182·4% in urban population against an increase of 16·8% in the total population. In 1900 there were seven cities having 3000 or more inhabitants: Sioux Falls with 10,266; Lead, 6210; Yankton, 4125; Aberdeen, 4087; Mitchell, 4055; Deadwood, 3498; and Waterton, 3352.[1]

In 1906 the total number of communicants of different religious denominations in the state was 161,951, of whom 61,014 were Roman Catholics, 45,018 Lutherans, 16,143 Methodists, 8599 Congregationalists, 7055 Protestant Episcopalians, 6990 Presbyterians and 6198 Baptists.

Administration.—The state is governed under its original constitution of 1889, with amendments of 1896, 1898, 1900, 1902, 1904 and 1909. The suffrage is granted to all males[2] resident in an election precinct for ten days, in the county for thirty days, in the state for six months, in the United States for one year, and 21 years of age, except those under guardianship or insane, and those convicted of treason or felony, unless restored to civil rights. The legislature may propose amendments to the constitution by a majority vote of all members elected to each of the two houses, or may issue a call for a constitutional convention by a two-thirds' majority. In either case the proposition must be ratified by popular vote at the next general election.

The chief administrative officers are a governor, secretary of state, auditor, treasurer (not eligible for more than two consecutive terms), superintendent of public instruction, attorney-general, and commissioner of school and public lands, all elected biennially by direct popular vote. The governor and lieutenant-governor must be citizens of the United States, qualified electors of the state, at least thirty years old, and residents of the state for two years preceding the election. The governor may remit fines and forfeitures, and grant reprieves, commutations and pardons, but in the more serious cases only on the recommendation of a board of pardons, composed of the presiding judge, the secretary of state, and the attorney-general. He has a veto power extending to items in appropriation bills, which may be overcome by a two-thirds' vote in each house. A lieutenant-governor, chosen biennially, presides over the senate.

The legislative department consists of a Senate (with not fewer than twenty-five and not more than forty-five members) and a House of Representatives (with not fewer than seventy-five and not more than 135 members) chosen biennially. Senators and representatives must be qualified electors, citizens of the United States, at least twenty-five years old, and residents of the state for two years next preceding election. The sessions of the legislature are biennial and are limited to sixty days. Bills may originate in either house, and either house may amend the bills of the other house. A constitutional amendment providing for minority representation in the House of Representatives was rejected in 1889 by a large popular vote. South Dakota was the first American state to adopt the initiative and referendum. Under a constitutional amendment, adopted by popular vote on the 8th of November 1898, 5% of the legal voters of the state may require the legislature to submit to popular vote at the next general election measures which they wish enacted into law, or measures already passed by the legislature which have not yet gone into force. Exceptions to the referendum are made in the case of laws necessary for the immediate preservation of the public peace, health, or safety, or the support of the state government or the various state institutions. In practice the legislature has interpreted these exceptions so freely that nearly all important laws are passed with emergency clauses. The governor's veto does not apply to measures passed by popular vote.

The judicial department consists of the supreme court, circuit courts, county courts, justices of the peace, and police

[1] In 1905, according to a state census, there were nine cities with 3000 or more inhabitants, showing some changes in order of size: Sioux Falls, 12,283; Lead, 8052; Aberdeen, 5841; Mitchell, 5719; Watertown, 5164; Deadwood, 4364; Yankton, 4189; Huron, 3783; Brookings, 3265. Pierre, the capital, had a population of 2794.

[2] The constitution provided for the submission to the people in November 1890 of the question whether the word "male" in Article vii. of the constitution as adopted be omitted, but the popular vote in 1890 and again in 1898 did not favour this change. In the original constitution it was provided that any woman having the qualifications as to age, residence and citizenship might vote at any election held solely for school purposes and "hold any office in this state except as otherwise provided in this constitution."

magistrates. The supreme court consists of five judges chosen for six years—the term for the first judges elected under the constitution of 1889 was four years. The state is divided into five districts and one judge is chosen from each district, although the election is made by the voters of the state at large. The court has appellate jurisdiction only, except for the power to issue writs of *mandamus, quo warranto, certiorari,* injunction and other original and remedial writs. The state is divided into ten circuits, and one judge is elected by the voters of each circuit for a period of four years. The legislature may, by a two-thirds' vote of each house, increase the number of circuits or the number of judges. The circuit courts have original jurisdiction of all actions and causes, both at law and in equity and such appellate jurisdiction as may be conferred by law. In each county there is a county court with a county judge who is elected by popular vote for two years. The court has original jurisdiction in probate cases, in civil cases involving $1000 or less, and in criminal cases below the grade of felony. Under an act of 1893 three-fourths of a jury may render a verdict in lesser civil cases in county and circuit courts. The jurisdiction of justices of the peace is determined by law, but it is restricted by the constitution to cases involving $100 or less.

For the administration of local government the state is divided into counties (64 in 1910) and these in turn are subdivided into townships and municipal corporations. Although the township exists throughout the state, in many cases it is organized only for school purposes and in many others its jurisdiction is so restricted as not to extend to the villages and boroughs within its limits. The county authority is a board of commissioners elected on a general ticket, the township authority a board of supervisors or trustees. For each county there are a judge, clerk of the court, sheriff, auditor, registrar of deeds, treasurer, state's attorney, surveyor, coroner and superintendent of schools, all elected biennially.

Miscellaneous Laws.—A primary law enacted in 1905 authorizes the county convention of any party to provide for the nomination of candidates for county offices and the state legislature by direct vote. The state has had a varied experience in dealing with the liquor problem. A constitutional ordinance forbidding the manufacture, importation and sale of intoxicants was adopted on the 1st of October 1889 by a vote of 40,234 to 34,510. The decision of the United States Supreme Court in the case of *Leisy* v. *Hardin* in 1890 (see NORTH DAKOTA), and the lax enforcement of the ordinance in the larger towns soon resulted in an active movement for repeal. A state dispensary, similar to that of South Carolina (*q.v.*), was established in 1898 by a vote of 22,170 to 20,557, but it proved ineffective and was superseded in 1900 by the licence system. An attempt to introduce county local options was defeated in the election of 1908.

South Dakota long bore a notorious reputation for the laxity of its divorce laws. The grounds for action are still numerous. An act of 1907, ratified by popular vote in the election of 1908, raised the term of residence under which a person could apply for divorce from six months to one year, and provided that all cases should be tried openly at the regular term of court; and since the passage of this law Sioux Falls has ceased to be notorious for its divorce colony from other states. Neither husband nor wife has any interest in the separate property of the other and the wife may convey her real estate, other than a homestead, without her husband's consent, but the husband must support his wife out of his property or by his labour if he is able, and if he is unable the wife must support him so far as possible out of her property. The one may enter into contract with the other respecting property, and they may hold property as joint tenants. The descent of the estate of a husband dying intestate is the same as that of a wife dying intestate; if there is only one child, or the issue of only one child, the surviving spouse is entitled to one-half of the estate; if more than one child, to one-third of the estate; and if no children, father, mother, brother or sister, to the whole of the estate. The homestead of any family in the state is exempt from attachment, lien or forced sale, except for taxes or purchase money, provided it has been properly recorded; but it can embrace only one dwelling house, cannot include gold or silver mines, and is limited in value to $5000 to one acre if within a town plat, to 40 acres if it is in the country and was acquired under the laws of the United States relating to mineral lands, and to 160 acres of other land in the country. If the owner is married the homestead cannot be sold or mortgaged without the concurrence of both husband and wife. Upon the death of either husband or wife the exemption may be continued for the benefit of the surviving spouse, and upon the death of both husband and wife the exemption may be continued until the youngest child is of age.

Education.—At the head of the public-school system is a superintendent of public instruction chosen for two years. In each county there is a county superintendent, and in each school district a board of directors. When the state was admitted into the union two sections of land (1280 acres) in each township were set aside for educational purposes. The permanent school fund amounted to $4,852,567 on the 1st of July 1907. In 1908 the total expenditures for public schools were $3,152,006 ($1,633,594 being for teachers' salaries) and the total receipts were $3,853,695, of which $2,283,038 was from district taxes. In 1910 the total permanent school fund was $7,725,583 and the estimated value of the unsold lands held for the common schools and other educational endowments was $3,068,172. The schools are open to all pupils between the ages of six and twenty-one, and attendance for twelve weeks each year, eight of which must be consecutive, is compulsory for those between the ages of eight and fourteen. In the school year 1907–1908 77% of all persons of school age were enrolled in the public schools. The educational institutions of the state are all under the management of a board of regents of five members, who are appointed by the governor, with the approval of the senate for terms of six years. The leading state institutions are the state university (1882) at Vermilion, the agricultural college (1884) and the agricultural experiment station at Brookings, the state school of mines (1886) at Rapid City, and normal schools at Spearfish, Madison, Aberdeen and Springfield. The state university is under the control of the board of regents, and is maintained by the state and is the beneficiary of 86,000 acres of land grants from the Federal government. The city of Vermilion and Clay county and private persons have contributed largely to its support. It has a geological and mineralogical museum and under its supervision is carried on the state geological and natural history survey, the state geologist being head of the department of geology and mineralogy of the university. The university includes a college of arts and sciences, a school of commerce, an art department and colleges of law, music and engineering. The university (1910) had 51 instructors and 385 students. Denominational colleges are Yankton College (1882) and Redfield College (1887), both Congregational; Huron College (1883, Presbyterian), and Dakota Wesleyan University (1885; Methodist Episcopal) at Mitchell. The Norwegian Lutherans have a normal school at Sioux Falls, and the Roman Catholics have schools of higher grade at Sioux Falls, Deadwood and Aberdeen.

Charitable Institutions, &c.—The state maintains a school for the blind at Gary, a school for deaf mutes at Sioux Falls, a tuberculosis sanatorium at Custer, a general hospital for the insane at Yankton, a school for the feeble-minded at Redfield, a soldiers' home at Hot Springs, a reform school at Plankinton, and a penitentiary at Sioux Falls. All penal and charitable institutions are subject to the control of a state board of charities and corrections composed of five members appointed by the governor. A children's home at Sioux Falls is partly under state control. There is a Federal hospital for insane Indians at Canton.

Finance.—The general property tax is the chief source of revenue for state, county and local purposes. There is a local board of assessment and equalization in each county and a general board for the state at large. Corporations are reached through the general property tax, but there is a small levy on fire insurance companies for the support of the local fire departments. An inheritance tax was adopted in 1905 which progresses in proportion to the distance of relationship and the amount of the inheritance.[1] Poll taxes are levied by the counties and townships for school and local purposes. The current revenues of the state for the year ending on the 1st of July 1909, including cash on hand at the beginning of the year, were $4,148,734; for the same year the expenditures were $3,358,847. There is a small nominal indebtedness, less than the cash surplus in the treasury. The constitution fixes the debt limit at $100,000 over and above the share of the territorial debt assumed at the time of the formation of the state. The first national bank within the present limits of the state was organized at Yankton in 1872.

History.—The first authentic explorations in what is now South Dakota were made by the Lewis and Clark expedition in 1804 and 1806. The "Yellowstone," a steamboat sent out by the American Fur Company, ascended the Missouri to Fort Pierre in 1831 and to the mouth of the Yellowstone river in 1832. Among the passengers on the second trip was the well-known painter and ethnologist, George Catlin, who spent several weeks at Fort Pierre studying the manners and customs of the Indians. Explorations were also made by Prince Maximilian of Neuwied in 1832, by John C. Frémont in 1838, by Edward Harris and John J. Audubon in 1843, and by various others. Fort Pierre, which was founded by the American Fur Company about 1832, was sold to the United States government

[1] The rate for direct heirs and brothers and sisters is non-progressive.

in 1855, and was converted into a military post. A settlement was made at Sioux Falls in 1856, but was abandoned about six years afterwards. In the meantime several small colonies had been established east of the Missouri River, but growth was much hampered by the Civil War and by Indians. Although it was not the centre of operations, the south of the territory suffered considerably in the various uprisings under Spotted Tail, Red Cloud and Sitting Bull in 1863–65, 1867, and 1875–76 (see NORTH DAKOTA and CUSTER, GEORGE ARMSTRONG). A railway (part of the Chicago, Milwaukee & St Paul system) was built from Sioux City to Yankton in 1872–1873, and in 1874 General Custer led an exploring expedition into the Black Hills, which resulted in the discovery of gold and the rapid settlement of a considerable portion of the west of the territory. A movement was at once begun to break up the great Sioux reservation, partly because it cut off this region from the older settlements east of the Missouri and partly because it contained a large amount of land which was very valuable for farming and grazing purposes. In 1876 the Indians ceded their title to lands in the Black Hills. Under the Dawes Allotment Act of February 1887, and a special statute of March 1889, an agreement was made with some Indians, and about 11,000,000 acres, or about half of the reserve, was thrown open to settlement on the 10th of February 1890. This included, roughly speaking, all of the land between the Missouri River and the Black Hills and between the White River and the Big Cheyenne and a strip extending north from the Black Hills to the North Dakota line between the 102nd and 103rd meridians. The remainder was divided into six smaller reservations, Standing Rock, lying partly in North Dakota, and Cheyenne River, Lower Brulé, Crow Creek, Rosebud, and Pine Ridge in South Dakota. Angered by this sacrifice of their lands and excited by prophecies of the coming of the Messiah, a considerable number of the Indians went on the warpath, but after a short campaign they were defeated by General Nelson A. Miles in the battle of Wounded Knee on the 29th of December 1890, and were compelled to make their submission. Since that time the whites have steadily encroached on the reservations. About 56,560 acres of Lower Brulé lands were opened for settlement in 1889, about 1,600,000 acres of Sisseton and Wahpeton lands[1] in 1892, 168,000 acres of the Yankton Sioux lands in 1895, 416,000 acres of the Rosebud lands in 1904, and 800,000 acres in 1908.

The territory included within the present limits of the state was a part of the district of Louisiana from 1803 to 1805, of the territory of Louisiana from 1805 to 1812, and of the territory of Missouri from 1812 to 1820. After the formation of the state of Missouri in 1820 it remained unorganized, the section east of the Missouri River until 1834, and the section west until 1854. The eastern section was successively a part of the territories of Michigan 1834–1836, Wisconsin 1836–1838, Iowa 1838–1849 and Minnesota 1849–1858, and the western section a part of the territory of Nebraska 1854–1861. On the admission of Minnesota into the Union in 1858, the eastern section was again left unorganized until the 2nd of March 1861, when the territory of Dakota was created, including the present Dakotas and portions of Wyoming and Montana. With the organization of the territory of Idaho in 1863 and the settlement of the southern boundary in 1870 and 1882, the Dakotas acquired their present territorial limits (see NORTH DAKOTA). The inhabitants of the south of the territory held a convention at Sioux Falls in 1885, adopted a state constitution on the 3rd of November, and applied for admission into the Union. A proposition to divide the territory into two states at the forty-sixth parallel was sanctioned by popular vote in the election of November 1887. In accordance with the Enabling Act, which received the President's approval on the 22nd of February 1889, a convention met at Sioux Falls on the 4th of the following July and re-adopted, with some slight verbal changes, the constitution of 1885. This was ratified at the polls on the 1st of October, together with a separate prohibition clause, which was carried by a vote of 40,234 to 34,510 (see *Administration*). On the 2nd of November 1889 President Harrison issued a proclamation declaring South Dakota a state. Subsequently, notwithstanding a temporary set-back due to the panic of 1893, there was a rapid increase of population and wealth. The immigrants came mainly from the northern states and from Scandinavia. In national politics South Dakota has been consistently Republican, except in the election of 1896, when, as a result of the hard times which followed the panic, the Populists and Democrats were able to form a coalition and carry the state for William J. Bryan.

Grantham, (ed.) *Statutes of South Dakota* (2nd revised ed., 2 vols., 1901); Deane Robinson, *A Brief History of South Dakota* (New York, 1905); J. F. Kelly, *Manual of the Township and Road Laws of South Dakota 1907*; the state constitution, biennial reports of the auditor, secretary of state and superintendent of public instruction, and annual reports of the railway commissioners, insurance department and treasurer.

SOUTHEND-ON-SEA, a municipal borough and watering-place in the south-east parliamentary division of Essex, England, on the estuary of the Thames. Pop. (1901), 28,857. Area, 5172 acres. It is 36 m. E. from London by the London, Tilbury & Southend railway; and is served also by the Great Eastern railway, and during the summer by steamers from London. It first sprang into notice from a visit of Queen Caroline in 1804, and as it is the nearest seaside resort to London it is much frequented. The bathing is good, but the tide recedes with great rapidity and for nearly a mile. The pier, which is over $1\frac{1}{4}$ m. in length, permits the approach of steamers at all tides. Westcliff-on-Sea, a western suburb, has a station on the London and Tilbury line. Westward again is Leigh-on-Sea (an urban district, pop. 3667); its lofty Perpendicular church tower is visible from afar. At Hadleigh, 4m. west, there is a Salvation Army farm colony. The church of Hadleigh is Norman, with an eastern apse, and later additions. The castle was built in the 13th century, and two ruined towers and other fragments remain. Thorpe Bay is a residential suburb about midway between Southend and Shoeburyness. Eastwood, Great Wakering and Little Wakering are parishes in the neighbourhood. Southend was incorporated a municipal borough in 1894, under a mayor, 6 aldermen, and 18 councillors; in 1910 these numbers were increased to 8 aldermen and 24 councillors.

SOUTHERNE, THOMAS (1660–1746), English dramatist, was born at Oxmantown, near Dublin, in 1660, and entered Trinity College in 1676. Two years later he was entered at the Middle Temple, London. His first play, *The Persian Prince, or the Loyal Brother* (1682), was based on a contemporary novel. The real interest of the play lay not in the plot, but in the political significance of the personages. Tachmas, the "loyal brother," is obviously a flattering portrait of James II., and the villain Ismael is generally taken to represent Shaftesbury. The poet received an ensign's commission in Princess Anne's regiment, and rapidly rose to the rank of captain, but his military career came to an end at the Revolution. He then gave himself up entirely to dramatic writing. In 1692 he revised and completed *Cleomenes* for Dryden; and two years later he scored a great success in the sentimental drama of *The Fatal Marriage, or the Innocent Adultery* (1694). The piece is based on Mrs Aphra Behn's *The Nun*, with the addition of a comic underplot. It was frequently revived, and in 1757 was altered by David Garrick and produced at Drury Lane. It was known later as *Isabella, or The Fatal Marriage*. The general spirit of his comedies is well exemplified by a line from *Sir Anthony Love* (1691)—"every day a new mistress and a new quarrel." This comedy, in which the part of the heroine, disguised as Sir Anthony Love, was excellently played by Mrs Mountfort, was his best. He scored another conspicuous success in *Oroonoko, or The Royal Slave* (1696). For the plot of this he was again indebted to the novel by Mrs Behn. In his later pieces "Honest Tom Southerne" did not secure any great successes, but he contrived to gain better returns from his plays than Dryden did, and he remained a favourite with his contemporaries and with the next literary generation. He died on the 22nd of May 1746.

His other plays are: *The Disappointment, or the Mother in Fashion* (1684), founded in part on the *Curioso Impertinente* in Don Quixote; *The Wives' Excuse, or Cuckolds make themselves* (1692); *The Maid's Last Prayer; or Any, rather than fail* (1692); *The Fate of Capua* (1700); *The Spartan Dame* (1719), taken from Plutarch's Life of Aegis; and *Money the Mistress* (1729).

See *Plays written by Thomas Southerne, with an Account of the Life and Writings of the Author* (1774).

SOUTHEY, ROBERT (1774–1843), English poet and man of letters, was born at Bristol on the 12th of August 1774. His father, Robert Southey, an unsuccessful linendraper, married a Miss Margaret Hill in 1772. When he was three, Southey passed into the care of Miss Elizabeth Tyler, his mother's half-sister, at Bath, where most of his childhood was spent. She was a whimsical and despotic person, of whose household he has left an amusing account in the fragment of autobiography written in a series of letters to his friend John May. Before Southey was eight years old he had read Shakespeare and Beaumont and Fletcher, while his love of romance was fostered by the reading of Hoole's translations of Tasso and Ariosto, and of the *Faerie Queene*. In 1788 he was entered at Westminster school. After four years there he was privately expelled by Dr William Vincent (1739–1815), for an essay against flogging which he contributed to a school magazine called *The Flagellant*. At Westminster he made friends with two boys who proved faithful and helpful to him through life; these were Charles Watkyn Williams Wynn and Grosvenor Bedford. Southey's uncle, the Rev. Herbert Hill, chaplain of the British factory at Lisbon, who had paid for his education at Westminster, determined to send him to Oxford with a view to his taking holy orders, but the news of his escapade at Westminster had preceded him, and he was refused at Christ Church. Finally he was admitted at Balliol, where he matriculated on the 3rd of November 1792, and took up his residence in the following January. His father had died soon after his matriculation.

At Oxford he lived a life apart, and gained little or nothing from the university, except a liking for swimming and a knowledge of Epictetus. In the vacation of 1793 Southey's enthusiasm for the French Revolution found vent in the writing of an epic poem, *Joan of Arc*, published in 1796 by Joseph Cottle, the Bristol bookseller. In 1794 Samuel Taylor Coleridge, then on a visit to Oxford, was introduced to Southey, and filled his head with dreams of an American Utopia on the banks of the Susquehanna. The members of the "pantisocracy" were to earn their living by tilling the soil, while their wives cared for the house and children. Coleridge and Southey soon met again at Bristol, and with Robert Lovell developed the emigration scheme. Lovell had married Mary Fricker, whose sister Sara married Coleridge, and Southey now became engaged to a third sister, Edith. Miss Tyler, however, would have none of "pantisocracy" and "aspheterism," and drove Southey from her house. To raise the necessary funds for the enterprise Coleridge and he turned to lecturing and journalism. Cottle generously gave Southey £50 for *Joan of Arc*; and, with Coleridge and Lovell, Southey had dashed off the drama, printed as the work of Coleridge, on *The Fall of Robespierre*. A volume of *Poems* by R. Southey and R. Lovell was also published by Cottle in 1795. Southey's uncle, Mr Hill, now desired him to go with him to Portugal. Before he started for Corunna he was married secretly, on the 14th of November 1795, to Edith Fricker. On his return to England his marriage was acknowledged, and he and his wife had lodgings for some time at Bristol. He was urged to undertake a profession, but the Church was closed to him by the Unitarian views he then held, and medicine was distasteful to him. He was entered at Gray's Inn in February 1797, and made a serious attempt at legal study, but with small results. At the end of 1797 his friend Wynn began an allowance of £160 a year, which was continued until 1806, when Southey relinquished it on Wynn's marriage. His *Letters written during a Short Residence in Spain and Portugal* were printed by Cottle in 1797, and in 1797–1799 appeared two volumes of *Minor Poems* from the same press. In 1798 he paid a visit to Norwich, where he met Frank Sayers and William Taylor, with whose translations from the German he was already acquainted. He then took a cottage for himself and his wife at Westbury near Bristol, and afterwards at Burton in Hampshire. At Burton he was seized with a nervous fever which had been threatening for some time. He moved to Bristol, and after preparing for the press his edition of the works of Thomas Chatterton, undertaken for the relief of the poet's sister and her child, he sailed in 1800 for Portugal, where he began to accumulate materials for his history of Portugal. He also had brought with him the first six books of *Thalaba the Destroyer* (1801), and the remaining six were completed at Cintra. The unrhymed, irregular metre of the poem was borrowed from Sayers.

In 1801 the Southeys returned to England, and at the invitation of Coleridge, who held out as an inducement the society of Wordsworth, they visited Keswick. After a short experience as private secretary to Isaac Corry, chancellor of the exchequer for Ireland, Southey in 1803 took up his residence at Greta Hall, Keswick, which he and his family shared thenceforward with the Coleridges and Mrs Lovell. His love of books filled Greta Hall with a library of over 14,000 volumes. He possessed many valuable MSS., and a collection of Portuguese authorities probably unique in England. After 1809, when Coleridge left his family, the whole household was dependent on Southey's exertions. His nervous temperament suffered under the strain, and he found relief in keeping different kinds of work on hand at the same time, in turning from the *History of Portugal* to poetry. *Madoc* and *Metrical Tales and Other Poems* appeared in 1805, *The Curse of Kehama* in 1810, *Roderick, the last of the Goths*, in 1814. This constant application was lightened by a happy family life. Southey was devoted to his children, and was hospitable to the many friends and even strangers who found their way to Keswick. His friendship for Coleridge was qualified by a natural appreciation of his failings, the results of which fell heavily on his own shoulders, and he had a great admiration for Wordsworth, although their relations were never intimate. He met Walter Savage Landor in 1808, and their mutual admiration and affection lasted until Southey's death.

From the establishment of the Tory *Quarterly Review* Southey, whose revolutionary opinions had changed, was one of its most regular and useful writers. He supported Church and State, opposed parliamentary reform, Roman Catholic emancipation, and free trade. He did not cease, however, to advocate measures for the immediate amelioration of the condition of the poor. With William Gifford, his editor, he was never on very good terms, and would have nothing to do with his harsh criticisms on living authors. His relations with Gifford's successors, Sir J. T. Coleridge and Lockhart, were not much better. In 1813 the laureateship became vacant on the death of Pye. The post was offered to Scott, who refused it and secured it for Southey. A government pension of some £160 had been secured for him, through Wynn, in 1807, increased to £300 in 1835. In 1817 the unauthorized publication of an early poem on *Wat Tyler*, full of his youthful republican enthusiasm, brought many attacks on Southey. He was also engaged in a bitter controversy with Byron, whose first attack on the "ballad-monger" Southey in *English Bards and Scotch Reviewers* nevertheless did not prevent them from meeting on friendly terms. Southey makes little reference to Byron in his letters, but Byron asserts (*Letters and Journals*, ed. Prothero, iv. 271) that he was responsible for scandal spread about himself and Shelley. In this frame of mind, due as much to personal anger as to natural antipathy to Southey's principles, Byron dedicated *Don Juan* to the laureate, in what he himself called "good, simple, savage verse." In the introduction to his *Vision of Judgment* (1821) Southey inserted a homily on the "Satanic School" of poetry, unmistakably directed at Byron, who replied in the satire of the same name. The unfortunate controversy was renewed even after Byron's death, in consequence of a passage in Medwin's *Conversations of Lord Byron*.

Meanwhile the household at Greta Hall was growing smaller. Southey's eldest son, Herbert, died in 1816, and a favourite daughter in 1826; Sara Coleridge married in 1829; in 1834 his eldest daughter, Edith, also married; and in the same year Mrs Southey, whose health had long given cause for anxiety, became insane. She died in 1837, and Southey went abroad the next year with Henry Crabb Robinson and others. In 1839 he married his friend Caroline Bowles (see below). But his memory was failing, and his mental powers gradually left him. He died on the 21st of March 1843, and was buried in Crosthwaite churchyard. A monument to his memory was erected in the church, with an inscription by Wordsworth.

The amount of Southey's work in literature is enormous. His collected verse, with its explanatory notes, fills ten volumes, his prose occupies about forty. But his greatest enterprises, his history of Portugal and his account of the monastic orders, were left uncompleted, and this, in some sense, is typical of Southey's whole achievement in the world of letters; there is always something unsatisfying, disappointing, about him. This is most true of his efforts in verse. In his childhood Southey fell in with Tasso, Tasso led him to Ariosto, and Ariosto to Spenser. These luxuriantly imaginative poets captivated the boy; and Southey mistook his youthful enthusiasm for an abiding inspiration. His inspiration was not genuinely imaginative; he had too large an infusion of prosaic commonplace in his nature to be a true follower of Ariosto and Spenser. Southey, quite early in life, resolved to write a series of epics on the chief religions of the world; it is not surprising that the too ambitious poet failed. His failure is twofold: he was wanting in artistic power and in poetic sympathy. When his epics are not wildly impossible they are incurably dull; and a man is not fit to write epics on the religions of the world when he can say of the prophet who has satisfied the gravest races of mankind—Mahomet was "far more remarkable for audacious profligacy than for any intellectual endowments." Southey's age was bounded, and had little sympathy for anything beyond itself and its own narrow interests; it was violently Tory, narrowly Protestant, defiantly English. And in his verse Southey truthfully reflects the feeling of his age. In the shorter pieces Southey's commonplace asserts itself, and if that does not meet us we find his bondage to his generation. This bondage is quite abject in *The Vision of Judgment*; Southey's heavenly personages are British Philistines from Old Sarum, magnified but not transformed, engaged in endless placid adoration of an infinite George III. For this complaisance he was held up to ridicule by Byron, who wrote his own *Vision of Judgment* by way of parody.

Some of Southey's subjects, "The Poet's Pilgrimage" for instance, he would have treated delightfully in prose; others, like the "Botany Bay Eclogues," "Songs to American Indians," "The Pig," "The Dancing Bear," should never have been written. Of his ballads and metrical tales many have passed into familiar use as poems for the young. Among these are "The Inchcape Rock," "Lord William," "The Battle of Blenheim," the ballad on Bishop Hatto, and "The Well of St Keyne."

Southey was not in the highest sense of the word a poet; but if we turn from his verse to his prose we are in a different world; there Southey is a master in his art, who works at ease with grace and skill. "Southey's prose is perfect," said Byron; and, if we do not stretch the "perfect," or take it to mean the supreme perfection of the very greatest masters of style, Byron was right. In prose the real Southey emerges from his conventionality. His interest and his curiosity are unbounded as his *Common-Place Book* will prove; his stores of learning are at his readers' service, as in *The Doctor*, a rambling miscellany, valued by many readers beyond his other work. For biography he had a real genius. The *Life of Nelson* (2 vols., 1813), which has become a model of the short life, arose out of an article contributed to the *Quarterly Review*; he contributed another excellent biography to his edition of the *Works of William Cowper* (15 vols., 1833–1837), and his *Life of Wesley; and the Rise and Progress of Methodism* (2 vols., 1820) is only less famous than his *Life of Nelson*. But the truest Southey is in his *Letters*: the loyal, gallant, tender-hearted, faithful man that he was is revealed in them. Southey's fame will not rest, as he supposed, on his verse; all his faults are in that—all his own weakness and all the false taste of his age. But his prose assures him a high place in English literature, though not a place in the first rank even of prose writers.

Southey's love of romance appears in various volumes: *Amadis of Gaul* (4 vols., 1803); *Palmerin of England* (1807); *Chronicle of the Cid* (1808), and *The byrth, lyf and actes of King Arthur . . . with an introduction and notes* (1817). His other works are: *Specimens of English Poets* (3 vols., 1807); *Letters from England by Don Manuel Espriella* (3 vols., 1807), purporting to be a Spaniard's impressions of England; an edition of the *Remains of Henry Kirke White* (2 vols., 1807); *Omniana or Horae Otiosiores* (2 vols., 1812); *Odes to . . . the Prince Regent . . .* (1814); *Carmen Triumphale . . . and Carmina Aulica . . .* (1814); *Minor Poems . . .* (1815); *Lay of the Laureate* (1816), an epithalamium for the Princess Charlotte; *The Poet's Pilgrimage to Waterloo* (1816); *Wat Tyler: a dramatic poem* (1817); *Letter to William Smith Esq., M.P.* (1817), on the occasion of strictures made in the House of Commons on *Wat Tyler*; *History of Brazil* (3 vols., 1810, 1817, 1819); *Expedition of Orsua and the Crimes of Aguirre* (1821); *A Book of the Church* (2 vols., 1824); *A Tale of Paraguay* (1825); *Vindiciae Ecclesiae Anglicanae, Letters to C. Butler, Esq., comprising essays on the Romish Religion and vindicating the Book of the Church* (1826); *History of the Peninsular War* (3 vols., 1823, 1824, 1832); "Lives of uneducated Poets," prefixed to verses by John Jones (1829); *All for Love* and *The Pilgrim to Compostella* (1829); *Sir Thomas More, or Colloquies on the Progress and Prospects of Society* (2 vols., 1829); *Life of John Bunyan*, prefixed to an edition (1830) of the *Pilgrim's Progress*; *Select Works of British Poets from Chaucer to Jonson, edited with biographical notices . . .* (1831); *Essays Moral and Political . . . now first collected* (2 vols., 1832); *Lives of the Admirals, with an introductory view of the Naval History of England*, forming 5 vols. (1833–1840) of *Lardner's Cabinet Cyclopaedia*; *The Doctor* (7 vols., 1834–1847), the last two volumes being edited by his son-in-law, the Rev. J. Wood Warter; *Common-Place Book* (4th series, 1849–1851), edited by the same; *Oliver Newman; a New England Tale* (unfinished), *with other poetical remains* (1845), edited by the Rev. H. Hill. A collected edition of his *Poetical Works* (10 vols., 1837–1838) was followed by a one volume edition in 1847. Southey's letters were edited by his son Charles Cuthbert Southey as *The Life and Correspondence of the late Robert Southey* (6 vols., 1849–1850); further selections were published in *Selections from the Letters of Robert Southey* (4 vols., 1856), edited by J. W. Warter; and *The Correspondence of Robert Southey with Caroline Bowles. To which are added: Correspondence with Shelley, and Southey's Dreams* (1881), was edited, with an introduction, by Professor E. Dowden. An excellent selection from his whole correspondence, edited by Mr John Dennis, as *Robert Southey, the story of his life written in his letters* (Boston, Massachusetts, 1887), was reprinted in Bohn's Standard Library (1894). See also *Southey* (1879) in the English Men of Letters Series, by Professor E. Dowden, who also made the selection of *Poems by Robert Southey* (1895) in the Golden Treasury Series. A full account of his relations with Byron is given in *The Letters and Journals of Lord Byron* (vol. vi., 1901, edited R. E. Prothero), in an appendix entitled "Quarrel between Byron and Southey," pp. 377–399. Southey figures in four of the *Imaginary Conversotions* of W. S. Landor, two of which are between Southey and Porson, and two between Southey and Landor.

Southey's second wife, Caroline Anne Southey (1786–1854), was the daughter of an East Indian captain, Charles Bowles. She was born at Lymington, Hants, on the 7th of October 1786. As a girl Caroline Anne Bowles showed a certain literary and artistic aptitude, the more remarkable perhaps from the loneliness of her early life and the morbidly delicate condition of her health—an aptitude however of no real distinction. When money difficulties came upon her in middle age she determined to turn her talents to account in literature. She sent anonymously to Southey a narrative poem called *Ellen Fitzarthur*, and this led to the acquaintanceship and long friendship, which, in 1839, culminated in their marriage. *Ellen Fitzarthur* (1820) may be taken as typical, in its prosy simplicity, of the rest of its author's work. Mrs Southey's poems were published in a collected edition in 1867. Among her prose writings may be mentioned *Chapters on Churchyards* (1829), her best work; *Tales of the Moors* (1828); and *Selwyn in Search of a Daughter* (1835). It was soon after her marriage that her husband's mental state became hopeless, and from this time till his death in 1843, and indeed till her own, her life was one of much suffering. She was not on good terms with her stepchildren, and her share in Southey's life is hardly noticed in Charles Cuthbert Southey's *Life and Correspondence* of his father. But with Edith Southey (Mrs Warter) she was always in friendly relations, and she supplied the valuable additions to Southey's correspondence published by J. W. Warter. She is best remembered by her correspondence with Southey, which, neglected in the official biography, was edited by Professor Dowden in 1881. Mrs Southey died at Buckland Cottage, Lymington, on the 20th of July 1854, two years after the queen had granted her an annual pension of £200.

Besides the works already mentioned, Mrs Southey wrote *The Widow's Tale, and other Poems* (1822); *Solitary Hours* (prose and verse, 1826); *Tales of the Factories* (1833); *The Birthday* (1836); and *Robin Hood*, written in conjunction with Southey, at whose death this metrical production was incomplete.

SOUTHGATE, an urban district in the Enfield parliamentary division of Middlesex, England, 9 m. N. of St Paul's Cathedral, London, on the Great Northern railway. Pop. (1901), 14,993. It is pleasantly situated in a wooded district, and forms an outer residential suburb of the metropolis. Christ Church, in Early English style, is the work of Sir Gilbert Scott, and contains stained glass windows from the designs of Sir E. Burne-Jones and D. G. Rossetti. Close to New Southgate station is Colney Hatch Lunatic Asylum for the county of London, opened in 1851 and subsequently much enlarged.

SOUTH GEORGIA, an uninhabited British island in the South Atlantic Ocean, about 900 m. S. by E. of the Falklands, in 54°–55° S., 36°–38° W.; area 1600 sq. m. It is mountainous, with snowy peaks 6000 to 8000 ft. high, their slopes furrowed with deep gorges filled with glaciers. Its geological constitution—gneiss and argillaceous schists, with no trace of fossils—shows that the island is, like the Falklands, a surviving fragment of some greater land-mass now vanished, most probably indicating a former extension of the Andean system. At Royal Bay, on the south-east side, was stationed the German expedition sent out to observe the transit of Venus in 1882. The island would be well suited for cattle or sheep farming but for its damp, foggy climate. The flora is surprisingly rich, and the German naturalists were able to collect thirteen flowering plants, mostly common also to the Falklands, but one allied to a form found in distant New Zealand. South Georgia is politically attached to the Falklands.

SOUTH HADLEY, a township of Hampshire county, Massachusetts, U.S.A., on the Connecticut river, about 12 m. N. of Springfield. Pop. (1900), 4526, of whom 1119 were foreign-born; (1910 census), 4894. Area, 18·5 sq. m. There are no steam railways, but an electric line connects South Hadley and South Hadley Falls with the New York, New Haven & Hartford and the Boston & Maine railways at Holyoke. The village of South Hadley, or the Center, lies at the south base of Mount Holyoke, about 4 m. from Holyoke and about 3 m. from South Hadley Falls; it is the seat of Mount Holyoke College. South Hadley Falls are connected with Holyoke by a bridge across the Connecticut river. The falls of the river afford water-power for paper mills, cotton and woollen mills, and saw mills. South Hadley was originally a part of the township of Hadley, but in 1753 the district of South Hadley was established, and in 1775 incorporated as a separate township.

SOUTH HOLLAND, a province of Holland, bounded W. by the North Sea, N. by North Holland, E. by Utrecht and Gelderland, S.E. by North Brabant, and S. by Zeeland. It has an area of 1166 sq. m., and a population (1905) of 1,287,363. Its south-eastern and southern boundaries are defined by the estuaries called the New Merwede, the Hollandsch Diep, the Volkerak, the Krammer, and Grevelingen, and the province includes the delta islands of Goeree (Goedereede) and Overflakkee, Voorne and Putten, Rozenburg, Yselmonde, Hoeksche Waard, and Dordrecht. The natural division into dunes, *geest* grounds, and clay and low fen holds for South as well as for North Holland. Noordwyk-on-Sea, Katwyk-on-sea, Scheveningen, and Ter Heide are watering-places and fishing villages. The Hook (Hoek) of Holland harbour, built at the mouth of the New Waterway (1866–1872) from Rotterdam, is the chief approach to Central Europe from Harwich on the east coast of England. At the foot of the dunes are the old towns and villages of Sassenheim, close to which are slight remains of the ancient castle of Teilingen (12th century), in which the countess Jacoba of Bavaria died in 1433. Among other places of interest are Rynsburg, the site of a convent for nobles founded in 1133 and destroyed in the time of Spanish rule; Voorschoten; Wassenaar, all of which were formerly minor lordships; Loosduinen, probably the Lugdunum of the Romans, and the seat of a Cistercian abbey destroyed in 1579; Naaldwyk, an ancient lordship; and 's Gravenzande, which possessed a palace of the counts of Holland in the 12th century, when it was a harbour on the Maas. The Hague, situated in the middle of this line of ancient villages, is the capital of the province. The market-gardening of the region called the Westland, between the Hague and the Hook of Holland, is remarkable, and large quantities of vegetables are exported to England. On the clay and low fen cattle-rearing and the making of the Gouda cheeses are the principal occupations. Flourishing centres of industry are found along the numerous river arms, including Maasluis, Vlaardingen, Schiedam, Rotterdam, Gorinchem, and Dordrecht. Here also are some of the oldest settlements, such as Vianen on the Lek, Leerdam on the Linge, and Woudrichem or Woerkum at the junction of the Maas and Merwede. Woudrichem guards the entrance to the Merwede in conjunction with Fort Loevestein on the opposite shore. Vianen is supposed to be the *Fanum Dianae* of Ptolemy, and was the seat of an independent lordship which passed to the family of Brederode in 1418, and later to the princes of Lippe-Detmold, from whom it was bought by the states in 1725. There is a fine tomb of Reinoud van Brederode (d. 1556) and his wife in the Reformed Church. The lordship of Leerdam arose out of a division of the lordship of van Arkel and descended to the house of Egmond. It was raised to a countship in 1492, and passed by marriage to the family of Orange-Nassau. The Reformed Church contains the tomb of John, last lord of van Arkel.

SOUTHINGTON, a township of Hartford county, Connecticut, U.S.A., about 15 m. S.W. of the city of Hartford. Within the township is the borough of Southington, served by the New York, New Haven & Hartford railroad. Pop. of the township (1910), 6516, which included that of the borough, 3714. The area of the township is 35 sq. m. The principal industry is the manufacture of hardware goods. Between 1809 and 1874 as many as 236 patents were granted to residents. Southington was originally a part of the township of Farmington. It was settled about 1697; in 1724 it became an independent parish under the name of Panthorn. The township was incorporated in 1779, the borough in 1889.

See H. R. Timlow's *Ecclesiastical and Other Sketches of Southington* (Hartford, 1875).

SOUTH MELBOURNE, a city of Bourke county, Victoria, Australia, separated from Melbourne in 1855, proclaimed a city in 1883, and formerly known as Emerald Hill. Pop. (1901), 40,637. It returns three members to parliament and contains the residence of the governor of the colony. The wharves on the river Yarra and its numerous manufactures contribute to the wealth and importance of the city.

SOUTH MOLTON, a market town and municipal borough in the South Molton parliamentary division of Devonshire, England, on the river Mole, 197 m. W. by S. of London, by the Great Western railway. Pop. (1901), 2848. Besides the parish church of St Mary Magdalene, a fine and massive Perpendicular building with an ancient pulpit of carved stone, there are a guildhall and market house. Linen goods are manufactured; fairs are held twice yearly, and numerous flour mills are worked by the river. The town is governed by a mayor, 4 aldermen, and 12 councillors. Area, 5910 acres.

South Molton (*Sud Moutona*) was probably the site of a very early settlement, the remains of a British camp being visible 2 m. south of the town, but its authentic history begins with the Domesday survey, which relates that the manor had been royal demesne of Edward the Confessor and now paid £10 a year to the Conqueror. In the 13th century it was held by Nicholas Fitz Martin of the earl of Gloucester for the service of finding a bow with three arrows to attend the earl when he should hunt in Gower. In 1246 Nicholas obtained a grant of a Saturday market and a fair at the feast of the Assumption (both maintained up to the present day), and in 1275 South Molton appears for the first time as a mesne borough under his overlordship. The borough subsequently passed to the Audleys, the Hollands, and in 1487 was granted for life to Margaret, duchess of Richmond, who in 1490 obtained a grant of a fair (which is still held) at the nativity of St John the Baptist. It returned two members to parliament in 1302, but no charter of incorporation was issued until that of Elizabeth in 1590, instituting a common council of a mayor and eighteen burgesses, three of whom were to be elected capital burgesses, with a recorder, steward of the borough court, two sergeants-at-mace, and a court of record every three weeks on Monday. A fresh charter was issued by Charles II. in 1684. This remained in force until the Municipal Corporations Act of 1835. The town formerly had a considerable manufacture of serges and shalloons, or light woollen linings, so called from Châlons-sur-Marne, France.

SOUTH NORWALK, a city of Fairfield county, Connecticut, U.S.A., at the mouth of the Norwalk river, on Long Island Sound, in the township of Norwalk, and 42 m. by rail N.E. of New York. Pop. (1900) 6591, including 1528 foreign-born (many Hungarians) and 83 negroes; (1910) 8968. It is served by the main line and the Danbury division (of which it is a terminus) of the New York, New Haven & Hartford railway, by inter-urban electric lines, and by steamboats to New York. The business and manufacturing section is close to the river and only a few feet above it; behind this, along a ridge, is the residential district; along the Sound are summer cottages and pleasure resorts. West Avenue is a finely shaded drive. The city has a public library and a soldiers' monument. South Norwalk is chiefly a manufacturing and commercial city. It has a good harbour (in which there are three lighthouses), considerable coastwise trade, and important oyster fisheries. South Norwalk, long an unincorporated village called Old Well, was chartered as a city under its present name in 1870, and its charter was revised and amended in 1882, 1897 and 1909.

SOUTHOLD, a township of Suffolk county, New York, occupying the peninsula at the N.E. of Long Island, and including the islands E.N.E. of this peninsula, Plum Island, on which defences protect the eastern entrance to Long Island Sound, Little Gull Island, on which there is a lighthouse, Great Gull Island, and Fisher's Island. Pop. (1900), 8301; (1910, U.S. census), 10,577. Excluding the islands to the east, the township is about 25 m. long and its average width is 2 m.; the Sound shore is broken only by Mattituck and Goldsmith's inlets, but the southern shore is broken with bays and necks of land. The surface is hilly, with occasional glacial boulders. The Long Island railway serves the principal villages of the township, Mattituck, Cutchogue, Peconic, Southold and Greenport (pop. in 1910, 3089), and from Greenport steamers run to Shelter Island, Sag Harbor, New London and New York. Beyond Greenport are the villages of East Marion and Orient. Greenport has some shipping and some oyster fisheries, asparagus is grown at Mattituck, and Peconic Bay is noted for its scallops. Southold is a summer resort, and it is historically interesting as one of the first English settlements on Long Island. The first permanent settlement here was made in 1640; land was bought from the Indians in August (a lease from the proprietor William Alexander, Lord Stirling, had been secured in 1639), and on the 21st of October 1640 a Presbyterian church was organized under John Youngs, who came from New Haven and had been connected with a St Margaret's church in Suffolk, England, probably at Reydon, near Southwold; and it is possible that the settlement was named from Southwold, though as it was commonly called "the South Hold" by early writers and a settlement on Wading River was called West Hold, the name was probably descriptive. A meeting-house was built in 1642, and biblical laws were enforced. Southold was originally one of the six towns under the New Haven jurisdiction, but in 1662 was placed under Connecticut; in 1664 it objected strongly to the transfer of Long Island to the duke of York; in 1670 refused to pay taxes imposed by Governor Francis Lovelace of New York; in 1672 petitioned the king to be under Connecticut or to be a free corporation; in 1673, when the Dutch got control of New York, withstood the Dutch commissioners, with the help of Connecticut; and, in 1674, after English supremacy was again established in New York, still hoped to be governed from Connecticut. The township was chartered by Governor Edmund Andros in 1676. Greenport was not settled until the first quarter of the 19th century, and was incorporated as a village in 1838.

See Epher Whitaker, *History of Southold, L.I.: Its First Century* (Southold, 1881); *Southold Town Records* (2 vols., Southold, 1882–1884), and an address by C. B. Moore in *Celebration of the 250th Anniversary of the Formation of the Town and the Church of Southold, L.I.* (Southold, 1890).

SOUTH OMAHA, a city of Douglas county, Nebraska, U.S.A., on the high western bluffs of the Missouri, immediately adjoining Omaha on the south. Pop. (1900), 26,001, of whom 5607 were foreign-born; (1910, census) 26,259. It is served by the Chicago, Burlington & Quincy, the Chicago Great Western, the Chicago, Milwaukee & St Paul, the Chicago, Rock Island & Pacific, the Illinois Central, the Missouri Pacific, the Union Pacific, the Chicago & North Western, and the short Omaha Bridge Terminal railways. The principal public buildings are the Federal building (housing the post office and the bureau of animal industry), the public library and the live-stock exchange. Next to Chicago and Kansas City it is the greatest slaughtering and meat-packing centre in the United States. In 1905 it produced 43·5 % ($67,415,177) of the total value of the factory product of the state, and of this output 97·2% represented the slaughtering and packing industry. South Omaha was chartered as a city of the second class in 1887, and in 1901 became a city of the first class. The present city dates from 1884, when the Union stockyards were established here.

SOUTH ORANGE, a township and a village of Essex county, New Jersey, U.S.A., in the N.E. of the state, about 15 m. W. of New York City. Pop. of the village (1900), 4608, of whom 1140 were foreign-born; (1905) 4932; (1910) 6014. Pop. of the township, excluding the village (1900) 1630; (1905) 1946; (1910) 2979. The village is served by the Morris & Essex division of the Delaware, Lackawanna & Western railroad, and is connected with Orange and with Newark by electric lines. It is primarily a residential suburb of New York and Newark. On the Orange mountain is Essex county park, a wild tract with forest roads. The western part of the township is locally known as Maplewood, the eastern as Hilton. South Orange has a public library and a town hall, and is the seat of Seton Hall College (Roman Catholic), named in honour of Mother Elizabeth Seton, founded at Madison, N.J., in 1856, and removed to South Orange in 1860. Among the landmarks of South Orange are an old stone house of unknown date, but mentioned in legal documents describing the surrounding property as early as 1680; the Baldwin House (*c.* 1717); and the Timothy Ball House (1743). Settlements were made within the present limits of the township in the latter part of the 17th century by some of the founders of Newark. The township was created in 1861 from parts of the town of Orange and the township of Clinton. The citizens secured in 1869 a village charter providing a village president and a board of trustees; in 1904 the village was entirely separated from the township, except as regards school government. In 1891 a tract of 150 acres, known as Montrose Park and containing many handsome residences, was annexed to the village.

See H. Whittemore, *The Founders and Builders of the Oranges*, (Newark, 1896).

SOUTHPORT, a municipal and county borough and seaside resort in the Southport parliamentary division of Lancashire, England, immediately S. of the embouchure of the Ribble into the Irish Sea, 18½ m. N. by W. of Liverpool. It is served by the Lancashire & Yorkshire and London & North-Western railways, and by the Southport & Cheshire Lines Extension system. Pop. (1901), 48,083. Its foreshore consists of a great expanse of firm, bright sands, and the mildness of its winter climate is attributed to the radiation of heat from them. Its proximity to Liverpool and Manchester has drawn to it a large resident population, and its visitors number many thousands annually. The promenade along the shore is 2 m. in length; in its centre is the pier, 1 m. long, down which tramcars are drawn by a stationary steam-engine. Other facilities for outdoor enjoyment are provided in Hesketh Park (presented to the town by the Rev. Charles Hesketh, formerly rector of North Meols, and one of the lords of the manor), the Botanic Gardens, Kew Gardens, South Marine Park, and the Winter Gardens. The last, laid out at a cost of £130,000, include a large conservatory, a fine enclosed promenade, a theatre and an aquarium. The principal public buildings are the town hall, the Cambridge Hall (used for concerts, &c.), and an extensive range of markets. There are several infirmaries and hospitals, and a sanatorium for children. Southport has also a free library and art gallery, a literary and philosophical institute, and a college (Trinity Hall) for the daughters of Wesleyan ministers; and a museum and schools of science and art. An extensive service of electric tramways is maintained. The first considerable house in Southport (an inn for the reception of sea-bathers) was built in 1791, and soon after other houses were erected on the site now known as Lord Street, but the population in 1809 was only 100. Birkdale is a residential district adjacent to Southport on the south. In 1867 Southport received a charter of incorporation. It became a county borough in 1905. The corporation consists of a mayor, 10 aldermen and 30 councillors. Area, 5144 acres.

SOUTH PORTLAND, a city of Cumberland county, Maine, U.S.A., on Casco Bay, an arm of which separates it from Portland, with which it is connected by a ferry and four bridges. Pop. (1900) 6287 (763 foreign-born); (1910) 7471. South Portland is served by the Boston & Maine railway. It is the seat of the State (Reform) School for Boys. At Spring Point is Fort Preble, established in 1808 and now a coast artillery station; and at Portland Head is Fort Williams. The city has steel-rolling mills, car shops of the Boston & Maine railway, and ship-building interests, and manufactures marine hardware and varnish. South Portland was part of the old town of Cape Elizabeth (pop. in 1900, 887) until March 1895; the legislature granted it a city charter in 1895, which was not accepted by the town until December 1898.

SOUTHSEA, a seaside resort of Hampshire, England, part of the municipal and parliamentary borough of Portsmouth, with a terminal station (East Southsea) on a branch of the London & South-Western and London, Brighton & South Coast railways. It forms the southern and residential quarter of Portsmouth, and overlooks Spithead, the inlet of the English Channel between the Isle of Wight and the mainland on the north-east. There are two piers, and a parade along the sea-wall; and the sea-bathing is good. Southsea Castle was built by Henry VIII. at the southern extremity of Portsea Island. (See PORTSMOUTH.)

SOUTH SEA BUBBLE, the name given to a series of financial projects which originated with the incorporation of the South Sea Company in 1711, and ended nine years later in general disaster.

The idea at the root of the parent scheme was that the state should sell certain trading monopolies to a company in return for a sum of money to be devoted to the reduction of the national debt, and in the form which it took in 1711 it possibly owes its existence to Daniel Defoe, who discussed it frequently with Edward Harley (1664–1735), brother of Robert Harley, earl of Oxford. In 1711 the South Sea Company was formed, and was granted a monopoly of the British trade with South America and the Pacific Islands, the riches of which were popularly regarded as illimitable. Its promoters, mainly wealthy merchants, took over nearly £10,000,000 of the national debt, on which they were to receive interest at the rate of 6% in addition to £8000 a year for the expenses of arrangement. The £600,000 was secured on certain customs duties. The company prospered, and in 1713, when the Asiento treaty was signed with Spain, it received the lucrative monopoly of the slave trade with Spanish America. It was the special pride of the Tories, who regarded it as a rival to the Whig institution, the Bank of England. In 1716 it obtained further concessions under the new Asiento treaty, and in 1717 it advanced a further sum of £2,000,000 to the government, but its prospects were greatly darkened by the outbreak of war between England and Spain in 1718. Yet it continued to thrive, and early in 1718 the king became its governor.

Towards the end of 1719 the directors of the company put before the government, the head of which was Charles Spencer, 3rd earl of Sunderland, a more ambitious scheme. In return for further concessions the company offered to take over the whole of the national debt and to pay £3,500,000 for this privilege. At this time the amount of the debt was £51,300,000, the greater part of which consisted of terminable annuities, money lent to the state in return for a fixed income for life. The company would receive interest at the rate of 5% until 1727, when it would be reduced to 4%. The advantage which the government hoped to obtain from this bargain was obvious; it would rid itself of the unpopular and burdensome debt. The advantages hoped for by the company were much greater, although perhaps not equally obvious. The aim of the directors was to persuade the annuitants of the state to exchange their annuities for South Sea stock; the stock would be issued at a high premium and thus a large amount of annuities would be purchased and extinguished by the issue of a comparatively small amount of stock. Moreover, when this process had been carried out the company would still receive from the government a sum of something like £1,500,000 a year. Seriously alarmed at the proposals of the South Sea Company, the directors of the Bank of England offered the government £5,000,000 for the same privilege, but the company outbid them with an offer of £7,567,000. This was accepted, the necessary act of parliament being passed in April 1720. It is interesting to note that one of the most sturdy opponents of the scheme was Sir Robert Walpole.

The year 1719, when the South Sea scheme was projected, was remarkably favourable to an undertaking of the kind. It was the year when France went delirious over John Law and his Mississippi Company, and the infection spread to England. But before April 1720, when everything was ready, a terrible reaction had begun in France, confidence and prosperity giving way to ruin and disaster. Nevertheless, the directors proceeded with their plan, and in a few weeks they had persuaded over one-half of the government annuitants to become shareholders in the company. Meanwhile the stock of the company had been appreciating steadily in value, and when the new scheme was launched the public began to purchase it more eagerly than before. From 128½ at the beginning of the year the price rose to 330 in March, and in April the directors sold two and a quarter millions of stock at 300. In May the price rose to 550, in June to 890, and in July it touched 1000. At this tremendous premium the directors sold five millions of stock.

By this time the extraordinary success of the South Sea Company had produced a crowd of imitators, and the result was a wild mania of speculation, and its inevitable end—a crash. Hundreds of companies were formed, some of them being fortunate enough to secure the active support of royal and titled personages; thus the prince of Wales, afterwards George II., became governor of the Welsh Copper Company. Some of these new companies, like the Royal Exchange and the London Assurance, were perfectly legitimate and honourable undertakings, but the great majority put forward the most audacious and chimerical proposals for extracting money from the public. One was "for a wheel for perpetual motion"; another was for a "design which will hereafter be promulgated," and it has been estimated that the total capital asked for by the promoters of these schemes amounted to £300,000,000. Profiting by the sad experience of France, the British government made an attempt to check this movement, and an act was passed for this purpose early in 1720. A proclamation of the 11th of June against the promoters of illegal companies followed, and the directors of the South Sea Company persuaded the lords justices, who were acting as regents during the absence of the king, to abolish 86 companies as illegal.

In August the fall in the price of South Sea stock began, and in September, just as the "insiders" had sold out, it became serious. Instead of being a buyer every one became a seller, and the result was that in a few days the stock of the South Sea Company fell to 175, while the stocks of many other companies were unsaleable. In November South Sea stock fell to 135, and in four months the stock of the Bank of England fell from 263 to 145. Thousands were ruined, and many who were committed to heavy payments fled from the country. The popular cry was for speedy and severe vengeance, both on the members of the government and on the directors of the unfortunate company.

Parliament was called together on the 8th of December 1720, and at once both houses proceeded to investigate the affairs of the company, the lower house soon entrusting this to a committee of secrecy. To stem the tide of disaster Sir Robert Walpole proposed that the Bank of England and the East India Company should each take over nine millions of South Sea stock, but although this received the assent of parliament it never came into force. More to the liking of the people was the act of January 1721 which restrained the directors from leaving the kingdom and compelled them to declare the value of their estates. The committee of secrecy reported in February 1721, and it proved that there had been fraud and corruption on a large scale. The company's books contained entries which were entirely fictitious, and the favours which the directors had secured from the state had been purchased by gifts to ministers, some of whom had also made large sums of money by speculating in the stock. The chief persons implicated were John Aislabie (1670–1742), chancellor of the exchequer; James Craggs, joint postmaster-general; his son James Craggs, secretary of state; and to a lesser degree the earl of Sunderland and Charles Stanhope, a commissioner of the treasury. Aislabie, who was perhaps the most deeply implicated, resigned his office in January, and in March he was found guilty by the House of Commons of the "most notorious, dangerous and infamous corruption"; he was expelled from the house and was imprisoned. Both the elder and the younger Craggs died in March, while owing to the efforts of Walpole both Sunderland and Stanhope were acquitted, the latter by the narrow majority of three. By act of parliament the estates of the directors were confiscated; these were valued at £2,014,123, of which £354,600 was returned to them for their maintenance, the balance being devoted to the relief of the sufferers.

Under the guidance of Walpole parliament then proceeded to deal with the wreck. £11,000,000 had been lent by the directors of the South Sea Company on the security of their own stock, the debtors of the company including 138 members of the House of Commons. This debt was remitted on payment of 10% of the sum borrowed, this being afterwards reduced to 5%, and the £7,567,000 due from the company to the government was also remitted. More serious, perhaps, was the case of those persons who had exchanged the substance of a government annuity for the shadow of a dividend on South Sea stock. They asked that the state should again guarantee to them their incomes, but in the end they only received something like one-half of what they had enjoyed before the bubble.

The South Sea Company with a capital of nearly £40,000,000 continued to exist, but not to flourish. Various changes were made in the nature of its capital, and in 1750 it received £100,000 from the Spanish government for the surrender of certain rights. Its commercial history then ended, but its exclusive privileges were not taken away until 1807. In 1853 the existing South Sea annuities were either redeemed or converted into government stock. The London headquarters of the company were the South Sea House in Threadneedle Street.

SOUTH SHETLAND, a chain of islands on the border of the Antarctic region, lying about 500 m. S.E. of Cape Horn, between 61° and 63° 10′ S. and between 53° and 63° W., and separated by Bransfield Strait from the region composed of Danco Land, Palmer Land, Louis Philippe Land, &c. The more considerable islands from west to east are Smith (or James), Low (or Jameson), Snow, Deception, Livingstone, Greenwich, Robert, Nelson, King George I., Elephant, and Clarence. Deception Island is remarkable as of purely volcanic origin. On the south-east side an opening 600 ft. wide gives entrance to an internal crater-lake (Port Forster) nearly circular, with a diameter of about 5 m. and a depth of 97 fathoms. Voyagers in 1828 and 1842 reported that steam still issued from numerous vents, but Otto Nordenskjöld (*Antarctica*, London, 1905) found no exterior evidence of volcanic activity. Most of the islands are rocky and mountainous, and some of their peaks are between 6000 and 7000 ft. in height. Covered with snow for the greater part of the year, and growing nothing but lichens, mosses and some scanty grass, the South Shetlands are of interest almost solely as a haunt of seals, albatrosses, penguins and other sea-fowl. It has been supposed by many that the Dutch navigator Dirk Gerrits discovered the South Shetlands in 1598, but it appears probable that this story originated through confusion with another voyage in which Gerrits was not concerned (cf. H. R. Mill, *Siege of the South Pole*, p. 34 seq.). In 1819 William Smith of the English brig "Williams" observed the South Shetland coast on the 19th of February. Revisiting it in October, he landed on King George I. Island, taking possession for England; he also gave the whole chain the name it bears. In 1820 the naval lieutenant Edward Bransfield was sent in the "Williams" to survey the islands, which attracted the attention of American and British sealers, and became fairly well known through the visits of Antarctic explorers. A smaller group—Coronation Island, Laurie Island, &c.—lying 200 m. east of the South Shetlands, bears the name of South Orkney. It was discovered by the English captain, Powell, in 1821.

SOUTH SHIELDS, a seaport and municipal, county and parliamentary borough of Durham, England; at the mouth of the Tyne on its right bank, opposite North Shields, on a branch of the North-Eastern railway. Pop. (1901), 97,263. It is connected with North Shields and Tynemouth by steam ferries. The principal buildings are the church of St Hilda, with a picturesque old tower; the town hall in the market-place, exchange, customhouse, mercantile marine offices, public library and museum, grammar school, marine school, master-mariners' asylum and seamen's institute. There is a pleasant marine park. The principal industries are now the manufacture of glass and chemicals, and ship-building and ship refitting and repairing, for which there are docks capable of receiving the largest vessels. The Tyne dock has a water-area of 50 acres, the tidal basin of 10 acres, and the quays and yards about 300 acres. Coal from the collieries of the vicinity is largely exported. The trade returns of South Shields are included in the aggregate of the Tyne ports (see Newcastle-upon-Tyne). The South Pier at the mouth of the river is a massive structure about 1 m. in length, and the North Pier protects the river mouth from the Northumberland bank at North Shields. The parliamentary borough returns one member. The corporation consists of a mayor, 10 aldermen and 30 councillors. Area of municipal borough, 2044 acres.

On elevated ground near the harbour are the remains of a Roman fort guarding the entrance to the Tyne, where numerous coins, portions of an altar, and several sculptured memorial stones have been dug up, and testify to its occupation for a considerable period. The site of the old station was afterwards occupied by a fort of considerable strength, which was captured by the Scots under Colonel Stewart on the 20th of March 1644. The town was founded by the convent of Durham about the middle of the 13th century, but on account of the complaints of the burgesses of Newcastle an order was made in 1258, stipulating that no ships should be laden or unladen at Shields, and that no "shoars" or quays should be built there. Until the 19th century it was little more than a fishing station. In 1832 it received the privilege of returning a member to parliament, and in 1850 a charter of incorporation.

SOUTHWARK, a central metropolitan borough of London, England, bounded N. by the river Thames, E. by Bermondsey, S.E. by Camberwell and W. by Lambeth. Pop. (1901), 206,180. It is a poor and crowded district, and a large industrial population is employed in the riverside wharves and in potteries, glassworks and other manufactures. There are also large breweries, and the Hop Exchange is a centre of the hop trade. The borough is connected with the City of London by Blackfriars, Southwark and London bridges; the thoroughfares leading from these and the other road-bridges as far up as Lambeth converge at St George's Circus; another important junction is the "Elephant and Castle." Southwark is a bishopric of the Church of England created by act of 1904 (previously a suffragan bishopric in the diocese of Rochester), and also of the Roman Catholic Church. The cathedral of St Saviour belonged to the Augustinian priory of St Mary Overy, or Overies (*i.e.* St Mary over the river), receiving its present name after the suppression of the monasteries. It is cruciform, with a central tower, and has been so restored as to preserve its ancient beauty. Its style is mainly Early English, and among those buried here are Gower, Fletcher and Massinger, the poets, and Edmund, brother of William Shakespeare. The Roman Catholic cathedral of St George is a Gothic building by A. W. Pugin, in St George's Road. Near the "Elephant and Castle" is the Metropolitan Tabernacle, the original building of which, burnt down in 1898, became famous under the Baptist preacher, Charles Spurgeon. The principal benevolent institutions are Guy's Hospital, St Thomas's Street, founded in 1721 by Thomas Guy, with an important medical school; and Bethlehem Royal Hospital for the Insane, commonly corrupted to Bedlam, the origin of which is found in a priory of the 13th century founded within the City, beside the modern Liverpool Street. Other institutions are the Evelina Children's Hospital, the Royal Eye Hospital and the Borough Polytechnic Institute. In Newington Causeway is the Sessions House for the county of London (south of the Thames). The Robert Browning Settlement was founded in York Street, Walworth Road, in 1895 and incorporated in 1903, and in Nelson Square is the Women's University Settlement. The municipal borough includes the western and part of the Bermondsey divisions of the parliamentary borough of Southwark, and the borough of Newington, divided into the western and Walworth divisions; each division returning one member. The borough council consists of a mayor, 10 aldermen and 60 councillors. Area, 1131·5 acres.

The history of Southwark is intimately connected with that of the City of London. At an early date it was incorporated, and its familiar title of "The Borough" still survives. It came, at least in part, under the jurisdiction of the City in 1327. The citizens of London having suffered from the depredations of thieves and felons who escaped into Southwark, petitioned parliament for protection. Accordingly, Edward III., by letters patent, granted them for ever the town and borough, a privilege confirmed by Edward IV. In this connexion was constituted the Bridge Ward Without, the alderman of which is elected not by the borough, but by the other aldermen from among themselves. The authority of the City over the borough is now merely nominal.

The junction in Southwark of the great roads from the south of England for the passage of the Thames sufficiently accounted for the early origin of Southwark. The name is taken from the southward works or fortifications of London. Numerous Roman remains have been found. Southwark witnessed various episodes during the invasions of the Norsemen, and was fortified by the Danes against the City in the reign of Ethelred the Unready. Besides the priory of St Mary Overy, there was the hospital of St Thomas, founded in 1213 from the neighbouring priory of Bermondsey, and forming the origin of the great modern hospital of the same name in Lambeth (*q.v.*). The many historical associations of Southwark, contemporary memorials of which are almost wholly swept away, centre upon the district bordering the river, and formerly known as Bankside. In this locality was Winchester House, a seat of the bishops of Winchester for five centuries from 1107. At Bankside were the Bear and the Paris Gardens, used for the popular sport of bear and bull baiting; and the Globe theatre, the scene of the production of many of Shakespeare's plays for fifteen years after its erection in 1599. Southwark was further noted for its inns and its prisons. Among the first, the name of the "Tabard" is well known from its mention by Chaucer in detailing the company of pilgrims for Canterbury. Charles Dickens had an early acquaintance with Southwark, as his father was confined in the Marshalsea, one of several prisons here. The prison, no longer extant, and the church of St George the Martyr, where many prisoners, including Bishop Bonner (d. 1561), were buried, figure in the novel *Little Dorrit*. The existing church dates from 1736.

SOUTHWELL, ROBERT (*c.* 1561–1595), English Jesuit and poet, son of Richard Southwell of Horsham St Faith's, Norfolk, was born in 1560/61. The Southwells were affiliated with many noble English families, and Robert's grandmother, Elizabeth Shelley, figures in the genealogy of Shelley the poet. He was sent very young to the Roman Catholic college at Douai, and thence to Paris, where he was placed under a Jesuit father, Thomas Darbyshire. In 1580 he joined the Society of Jesus, after a two years' novitiate, passed mostly at Tournay. In spite of his youth he was made prefect of studies in the English college of the Jesuits at Rome, and was ordained priest in 1584. It was in that year that an act was passed, forbidding any English-born subject of the Queen who had entered into priest's orders in the Roman Catholic Church since her accession to remain in England longer than forty days on pain of death. But Southwell at his own request was sent to England in 1586 as a Jesuit missionary with Henry Garnett. He went from one Catholic family to another, administering the rites of his Church, and in 1589 became domestic chaplain to Ann Howard, whose husband, the first earl of Arundel, was in prison convicted of treason. It was to him that Southwell addressed his *Epistle of Comfort*. This and other of his religious tracts, *A Short Rule of Good Life*, *Triumphs over Death*, *Mary Magdalen's Tears* and a *Humble Supplication to Queen Elizabeth*, were widely circulated in manuscript. That they found favour outside Catholic circles is proved by Thomas Nash's imitation of *Mary Magdalen's Tears* in *Christ's Tears over Jerusalem*. After six years of successful labour Southwell was arrested. He was in the habit of visiting the house of Richard Bellamy, who lived near Harrow and was under suspicion on account of his connexion with Jerome Bellamy, who had been executed for sharing in Anthony Babington's plot. One of the daughters, Anne Bellamy, was arrested and imprisoned in the gatehouse of Holborn. She revealed Southwell's movements to Richard Topcliffe, who immediately arrested him. He was imprisoned at first in Topcliffe's house, where he was repeatedly put to the torture in the vain hope of extracting evidence about other priests. Transferred to the gatehouse at Westminster, he was so abominably treated that his father petitioned Elizabeth that he might either be brought to trial and put to death, if found guilty, or removed in any case from "that filthy hole." Southwell was then lodged in the Tower, but he was not brought to trial until February 1595. There is little doubt that much of his poetry, none of which was published during his lifetime, was written in prison. On the 20th of February 1595 he was tried before the court of King's Bench on the charge of treason, and was hanged at Tyburn on the following day. On the scaffold he denied any evil intentions towards the Queen or her government.

St Peter's Complaint with other Poems was published in April

1595 without the author's name, and was reprinted thirteen times during the next forty years. A supplementary volume entitled *Maeoniae* appeared later in 1595, and *A Foure fould Meditation of the foure last things* in 1606. This, which is not included in Dr A. B. Grosart's reprint (1872) in the Fuller Worthies Library, was published by Mr Charles Edmonds in his *Isham Reprints* (1895). *A Hundred Meditations of the Love of God*, in prose, was first printed from a MS. at Stonyhurst College in 1873. Southwell's poetry is euphuistic in manner. But his frequent use of antithesis and paradox, the varied and fanciful imagery by which he realizes religious emotion, though they are indeed in accordance with the poetical conventions of his time, are also the unconstrained expression of an ardent and concentrated imagination. Ben Jonson told Drummond of Hawthornden that he would willingly have destroyed many of his own poems to be able to claim as his own Southwell's "Burning Babe," an extreme but beautiful example of his fantastic treatment of sacred subjects. His poetry is not, however, all characterized by this elaboration. Immediately preceding this very piece in his collected works is a carol written in terms of the utmost simplicity.

See Dr Grosart's edition already mentioned. Southwell's poems were also edited by W. B. Turnbull in 1856. A memoir of him was drawn up soon after his death. Much of the material was incorporated by Bishop Challoner in his *Memoir of Missionary Priests* (1741), and the MS. is now in the Public Record Office in Brussels. See also Sidney Lee's account in the *Dict. Nat. Biog.*; Alexis Possoz, *Vie du Père R. Southwell* (1866); and a life in Henry Foley's *Records of the English Province of the Society of Jesus. Historic facts illustrative of the labours and sufferings of its members in the 16th and 17th centuries*, 1877 (i. 301–387). Foley's narrative includes copies of the most important documents connected with his trial, and gives full information of the original sources.

SOUTHWELL, a cathedral city in the Newark parliamentary division of Nottinghamshire, England, 16 m. N.E. of Nottingham by a branch of the Midland railway. Pop. (1901), 3161. The minster church of St Mary became a cathedral on the foundation of the episcopal see in 1884. The see covers the greater part of Nottinghamshire and Derbyshire, with small portions of Leicestershire, Lincolnshire and Staffordshire. The foundation of the earliest church here is attributed to the missionary Paulinus in the first half of the 7th century. Another followed, after the devastations of the Northmen, in 960, on the foundation of King Edgar. The building of the present church began in the reign of Henry I. Henry VIII., after the dissolution of the monasteries, contemplated the erection of the church into a cathedral. The cathedral is a magnificent cruciform building, 306 ft. in length, with massive Norman nave (61 ft. wide), transepts, central and two western towers; and Early English choir with transepts. There is an octagonal chapter house, resembling that at York, exhibiting the Decorated style in highest development. It is connected with the church by a cloister. The archbishops of York had a palace here dating from the 15th century. The "great chamber" was restored in 1882, and since 1904 the building has been converted into a residence for the bishops of Southwell.

The erection of the church at Southwell (*Sudwelle, Suwell, Suthwell*), probably the cause of the origin of the town, is attributed to the archbishop of York in the 7th century. In 958 land at Southwell was granted to the archbishop by Edwy. A detailed description of the great manor is given in Domesday. Southwell remained under the lordship of the see of York until it was taken over by the ecclesiastical commissioners. It was called a borough in the 13th century and down to the 17th, but no charter of incorporation is known. The town never returned representatives to parliament. In the reign of Edward I. the archbishop claimed by prescriptive right a five-days' fair at Pentecost, a three-days' fair at the translation of St Thomas and a Saturday market. Fairs are now held in April and December. The market was still held on Saturdays in 1894, but was then very small.

SOUTHWOLD, a municipal borough and watering-place in the Lowestoft parliamentary division of Suffolk, England, 12 m. S. by W. of Lowestoft, the terminus of the Southwold railway, which connects with the Great Eastern at Halesworth. Pop. (1901), 2800. The church of St Edmund's is a Perpendicular flint structure. In 1900 a pier 270 yds. long was constructed, and serves as a calling-place for pleasure steamers. A fine common south of the town is used for golf, lawn-tennis, cricket, and other sports. The town is governed by a mayor, 4 aldermen and 12 councillors. Area, 612 acres.

Southwold (*Sudwold, Suwold, Suthwaud*) owes its origin and prosperity to its herring fisheries, which were considerable in 1086, while the importance of its harbour increased with the decay of Dunwich. In 1461 the men of the town, tenants of the manor which had been granted by the monks of Bury St Edmunds to Gilbert, earl of Clare, and had passed to the Crown with the honour of Clare, claimed exemption from toll, pontage and similar dues as their prescriptive right. An act of 1489 incorporated the bailiffs and commonalty of the town and exempted them from harbour dues. These liberties were confirmed in 1505 by Henry VII., who also granted the corporation the town and manor to hold at fee-farm with certain rights of jurisdiction. Confirmatory chapters were granted by Henry VIII., Edward VI., Elizabeth, James I. and Charles II., and the town was governed by a royal charter of 1689 until the Municipal Reform Act of 1835. The weekly market, now the property of the corporation, was granted to the abbot of St Edmunds as lord of the manor in 1227 together with a yearly fair on the vigil of the feast of St Philip and St James. A fair is still held on Trinity Monday. In 1672 Southwold Bay, usually abbreviated as Solebay, was the scene of a battle between the English fleet under the duke of York and the Dutch under Ruyter, the French fleet holding aloof. The English suffered much, but the Dutch withdrew.

See "*Victoria County History*": *Suffolk*; T. Gardner, *An Historical account of Dunwich, Blithburgh and Southwold* (ed. 1754).

SOUTHWORTH, EMMA DOROTHY ELIZA NEVITTE (1819–1899), American novelist, was born in Washington, D.C., on the 26th of December 1819. She studied in a school kept by her stepfather, Joshua L. Henshaw, and in 1840 married Frederick H. Southworth, of Utica, N.Y. After 1843 she supported herself by teaching. Her first story, "The Irish Refugee," was published in the *Baltimore Saturday Visitor*. Her first novel, "Retribution," a serial for the *National Era*, published in book form in 1846, was so well received that she gave up teaching and became a regular contributor to various periodicals, especially the *New York Ledger*. She lived in Georgetown, D.C., until 1876, then in Yonkers, N.Y., and again in Georgetown, D.C., where she died on the 30th of June 1899.

Her novels numbered more than sixty; some of them were translated into German, French and Spanish; in 1872 an edition of thirty-five volumes was published in Philadelphia. They include *The Deserted Wife* (1850); *Mark Sutherland* (1853); *Hickory Hall* (1855); *Unknown* (1874); *Gloria* (1877); *The Trail of the Serpent* (1879); *Nearest and Dearest* (1881); *The Mother's Secret* (1883); *An Exile's Bride* (1887); *The Hidden Hand* (1888); and *Broken Pledges* (1891).

SOUVESTRE, ÉMILE (1806–1854), French novelist, was born on the 15th of April 1806. He was the son of a civil engineer, a native of Morlaix. He was by turns a bookseller's assistant, a private schoolmaster, a journalist, and master at the grammar schools of Brest and of Mülhausen. He settled in Paris in 1836, where he was made (1848) professor in a school for the instruction of civil servants. He began his literary career with a drama, played at the Théâtre français in 1828, the *Siège de Missolonghi*. In novel writing he did much better than for the stage, although he deliberately aimed at making the novel an engine of moral instruction. His best work is undoubtedly to be found in the charming *Derniers Bretons* (4 vols., 1835–1837) and *Foyer breton* (1844), where the folk-lore and natural features of his native province are worked up into story form, and in *Un Philosophe sous les toits*, which received in 1851 a well deserved academic prize. He also wrote a number of other works—novels, dramas, essays and miscellanies. He died in Paris on the 5th of July 1854.

SOUVRÉ, GILLES DE, MARQUIS DE COURTANVAUX, BARON DE LEZINES (*c.* 1540–1626), marshal of France, belonged to an old family of the Perche. He accompanied the duke of Anjou to Poland in 1573, and was appointed master of the wardrobe and captain of Vincennes when Anjou became Henry III. He remained in favour, despite the opposition of the queen-mother, Catherine de Médicis, fought at Coutras, defended Tours against the Leaguers, was named chevalier de Saint Esprit and governor of Touraine (1585), and was one of the first to recognize Henry IV. (1589), who subsequently entrusted him with the education of the dauphin. Louis XIII. rewarded him with the title of marshal in 1613. He died in Paris in 1626.

SOUZA-BOTELHO, ADÉLAIDE FILLEUL, Marquise de (1761–1836), French writer, was born in Paris on the 14th of May 1761. Her mother, Marie Irène Catherine de Buisson, daughter of the seigneur of Longpré, near Falaise, married a bourgeois of that town named Filleul. It was reported, though no proof is forthcoming, that Mme Filleul had been the mistress of Louis XV. Her husband became one of the king's secretaries, and Mme Filleul made many friends, among them Marmontel. Their eldest daughter, Julie, married Abel François Poisson, marquis de Marigny (1727–1781); Adélaide married in 1779 Alexandre Sebastien de Flahaut de la Billarderie, comte de Flahaut, a soldier of some reputation, who was many years her senior. In Paris she soon gathered round her a salon, in which the principal figure was Talleyrand. There are many allusions to their liaison in the diary of Gouverneur Morris. In 1785 was born her son Auguste Charles Joseph de Flahaut (*q.v.*), who was generally known to be Talleyrand's son. Mme de Flahaut fled from Paris in 1792 and joined the society of *émigrés* at Mickleham, Surrey, described in Mme d'Arblay's *Memoirs.* Her husband remained at Boulogne, where he was arrested on the 29th of January 1793 and guillotined. Mme de Flahaut now supported herself by writing novels, of which the first, *Adèle de Sénange* (London, 1794), which is partly autobiographical, was the most famous. She presently left London for Switzerland, where she met Louis Philippe, duke of Orleans. She travelled in his company to Hamburg, where she lived for two years, earning her living as a milliner. She returned to Paris in 1798, and on the 17th of October 1802 she married José Maria de Souza-Botelho Mourão e Vasconcellos (1758–1825), Portuguese minister plenipotentiary in Paris. Her husband was recalled in 1804, and was offered the St Petersburg embassy; but in the next year he resigned, to settle permanently in Paris, where he had many friends, among them the historian Sismondi. He spent his time chiefly in the preparation of a beautiful edition of the *Lusiads* of Camoens, which he completed in 1817. Mme de Souza lost her social power after the fall of the First Empire, and was deserted even by Talleyrand, although he continued his patronage of Charles de Flahaut. Her husband died in 1825, and after the accession of Louis Philippe she lived in comparative retirement till her death on the 19th of April 1836. She brought up her grandson, Charles, duc de Morny, her son's natural son by Queen Hortense. Among her later novels were *La Comtesse de Fargy* (1822) and *La Duchesse de Guise* (1831). Her complete works were published in 1811–1822.

See Baron A. de Maricourt, *Madame de Souza et sa famille* (1907); *Lettres inédites de J. C. L. de Sismondi . . . et de Madame de Souza* (Paris, 1863), ed. St René Taillandier; Sainte-Beuve, *Portraits de femmes* (1844); and for Mme de Filleul, MM. de Goncourt, *Les Maîtresses de Louis XV.* (1860) and J. F. Marmontel (1804).

SOVEREIGN, originally an adjective, meaning "supreme," especially having supreme or paramount power. The word in Middle English was *soverain* or *sovereyn*, and was taken through Old French from Low Latin *superanus*, chief, principal. The intrusive "g," which is due to a popular confusion of the termination of the word with "reign," dates, according to Skeat, from about 1570. The form "sovran," borrowed by Milton from Italian *sovrano, soprano*, is chiefly found as a poetical usage. As a substantive "sovereign" is applied to the supreme head of a state (see Sovereignty), and to the standard English gold coin, worth 20 shillings or £1 (see Pound). The gold sovereign was first struck in the reign of Henry VII. (1489); it was of gold of the standard fineness (994·8) and weighed 240 grains. It bore the figure of the king crowned, in royal mantle, seated on the throne, and holding the sceptre and orb. The sovereign was coined in successive reigns until that of James I., when the name "unite" was given to the coin to mark the union of the two kingdoms. The gold coinage of the kingdom was, until 1816, a secondary part of the monetary system, but in that year the silver standard was discontinued and a gold standard adopted. The sovereign was chosen the new unit of the currency, and the first issue took place in 1817. Its weight was fixed at 123·274 grains; its fineness at 916·66 or twenty-two carats. These standards of weight and fineness are those still in force. At the same time was issued the half-sovereign, of weight in proportion. The weight of 934½ sovereigns is exactly equivalent to twenty Troy pounds, and the weight of each individual sovereign is calculated on this basis. The sovereign is eleven-twelfths pure gold and one-twelfth alloy, copper being usual. The light colour of early Australian sovereigns was due to the use of silver instead of copper. Five-pound pieces were coined in the reigns of Queen Victoria and Edward VII. They were also authorized in the reign of George III. (as were two-pound pieces), but the dies were not completed before the death of that sovereign. Specimens were, however, subsequently struck. There were also some pattern pieces struck in the reign of George IV. Two-pound pieces were issued in the reign of George IV.; they were struck in the reign of William IV., but not issued for circulation; they are current coins of the reigns of Victoria and Edward VII. (See also Mint; Money.)

SOVEREIGNTY. The word sovereignty (Fr. *souveraineté*) is said to be derived from the medieval Latin word *supremitas*, i.e. *suprema potestas*, supreme power. (See Skeat's *Etymological Dictionary* as to various forms of the word, and Meyer, *Lehrbuch des deutschen Staatsrechts*, 15, as to its derivation.)

Sovereignty may be viewed in three ways: there is the historical explanation of its origin and growth, its rude beginning in the savage horde, its completion in the modern state; there is the analytical or juridical explanation; there is also what (for want of a better phrase) may be called the organic explanation of sovereignty.

History.

The following are some of the chief stages in the history of sovereignty: While society is in a rude state or only tribally organized there is no distinct sovereignty, no power which all persons habitually obey. Thus there is no sovereignty among wandering groups of Australian savages: each family is isolated, each horde is a loose and unstable collection. When the horde has become a tribe there may exist no definite sovereign. Distinct in time of war, the power of the chief may be fluctuating and faint in time of peace; even in time of war it may be subject to the authority of a council. Tribes of the same ethnic stock may form a sort of federation, permanent or temporary. "With the council of the confederacy," it has been said, "and, more generally, in the confederacy, sovereignty arises and the true political tradition is evolved" (F. H. Giddings, *Principles of Sociology*, p. 285). When the city and the state are conterminous the seat of sovereignty becomes defined. Such was the condition of things in Greece, as considered by Aristotle in his *Politics*. He discusses the question what is the supreme power in the state (3. 10), which he defines as an aggregate of citizens (3. i.), and he recognizes that it may be lodged in one, a few, or many. In his view the distinctive mark of the state is not so much sovereignty (7. 4) as self-sufficiency; a state is not a mere aggregate of persons; it is a union of them sufficient for the purposes of life (7. 8); sufficiency being "to have all things and to want nothing" (7. 5. 1). The Roman jurists say little, and only incidentally, as to sovereignty. But in the middle ages, under the influence of the Roman law, and with the belief in the existence of an empire entitled to universal sway, an absolutist theory of sovereignty was developed in the writings of the jurists who revived the study of that law: the emperor was sovereign; "quod principi placuit legis habet vigorem" (*Institutes*, i. 2. 6).

Those jurists often justified the *plenitudo potestatis* conceded to the emperor by the fact that he stood at the head of Christendom.

Among the theories prevalent in the middle ages was one that mankind formed a unity, with the pope and the emperor at the head of it: the universal Church and the universal emperor ruled the world (Rehm, *Geschichte der Rechtswissenschaft*, p. 198.) Even to Leibnitz, writing in the 17th century, it seemed that "totam Christianitatem unam velut Rempublicam componere, in qua Caesari auctoritas aliqua competit" (*Opera*, 4. 330). When the power of the emperor was weakened, and the idea of a universal ruler was gone, a new test of sovereignty was applied —that of external independence; the true sovereign states were *universitates superiorem non recognoscentes*. There were times and countries in the middle ages in which the collective power of the community was small: many of the great corporations were virtually autonomous; the central authority was weak; the matters as to which it could count upon universal obedience were few. In such circumstances the conception of sovereignty was imperfect. It has been suggested that the modern conception of it was evolved from the contest between three powers: the Church, the Roman Empire, of which the individual states in Europe were theoretically provinces, and the great landowners and corporations. Whatever may be the truth as to this, the modern theory is first clearly stated in Jean Bodin's book *On the Commonwealth* (French ed., 1576; Latin version, 1586), which was the first systematic study of sovereignty. Bodin defines the state thus: "Respublica est familiarum rerumque inter ipsas communium, summa potestate ac ratione moderata multitudo." His theory, which corresponded on the whole to the state of things in France in the time of Louis XI., was a theory of despotism. It may be also described as a type of the mechanical or juridical theory of sovereignty. According to Bodin, there is in the state unlimited one power: "Majestas est summa in cives ac subditos legibusque soluta potestas" (i. 8). There exists a central force from which are derived all the powers which make or give effect to laws; a power which he describes sometimes as "majestas summa potestas summum imperium." This was the conception expressed by Bossuet, "Tout l'état est en la personne du prince," or in Louis XIV.'s saying, "L'état c'est moi."

One favourite theory was that sovereignty originated in a social contract. It was assumed that the individual members of society, by express or implied pact, agree to obey some person or persons; sometimes it is described as an unqualified handing over; sometimes it is a transfer subject to qualifications, and with notice that in certain contingencies this will be withdrawn. Gierke, in his book *Johannes Althusius und die Entwickelung der naturrechtlichen Staatstheorie*, shows (p. 76) that the conception of a treaty or agreement as the basis of the state was in the middle ages a dogma which passed almost unchallenged, and that this theory was maintained up to a late period. It is to be found in the writings of Thomas Aquinas (*De Regimine principum*, 266), Marsilius of Padua, Buchanan, J. de Mariana, and F. Suarez. It is the kernel of the theories of Hobbes, Rousseau, Filmer and Locke. Among the clearest and most logical exponents of this theory was Hobbes, who in his *Leviathan* expounded his notion of an agreement by which absolute power was irrevocably transferred to the ruler. Pufendorf, with some variations, states the same theory. In his view there is a *pactum unionis*, followed by a *pactum subjectionis*. The best-known exponent of this theory of the source of sovereignty is Rousseau, who assumes the existence of a *pacte social*, the terms of which are: "Chacun de nous met en commun sa personne et toute sa puissance sous la suprême direction de la volonté générale; et nous reçevons encore chaque membre comme partie indivisible de tout" (*Du Contrat social*, i. c. 6).

It is convenient for the jurist to assume that in every state is one determined or determinable authority in which is vested sovereignty, and from which all other authorities derive their power. The assumption is not true of some states; the legal authority is divided among several persons or bodies. It is at best an unfruitful assumption; and the tendency of students of sociology is to treat discussions as to sovereignty much as modern physiologists treat discussions as to "vital force" or "vital principle." Comte, Spencer, Bagehot, Durkheim and Giddings, for example, refer to it, if at all, only briefly and incidentally; they conceive society as an organism, or at all events as a growing whole, no one part or force being the cause of all others, and all interacting; society is not the product of any agreement or of force alone, but of a vast variety of interests, desires and needs. Now the state or government comes at a certain stage of organization: small groups are drawn together; powerful corporations fall into line; a national feeling develops; eventually the state as we know it is formed. Sovereignty is a resultant of many forces. It may not exist as to some regions of conduct; as to others it may be weak and mutable; only in certain conditions is the sovereign power supreme as to all matters of conduct.

Among the different senses in which "sovereign" has been used are the following:—

a. "Sovereign" may mean titular sovereign—the king in the United Kingdom, the kaiser in Germany.

b. The legal sovereign: the person or persons who, according to the law of the land, legislate or administer the government.

c. The political or constitutional sovereign: the body of persons in whom the actual power at any moment or ultimately resides. Sometimes this is designated "the collective sovereignty."

d. Sovereignty is also used in a wider sense, as the equivalent of the power, actual or potential, of the whole nation or society (Gierke, 3. 568).

The distinction between real and nominal sovereignty was familiar to medieval writers, who recognized a double sovereignty, and distinguished between (1) the real or practical sovereignty resident in the people, and (2) the personal sovereignty of the ruler (Adolf Dock, *Der Souveranitätsbegriff*, &c., p. 13). By many writers sovereignty is regarded as resident not in any one organ, but in the *Gesammtperson* of the community (Maitland, *Political Theories of the Middle Ages*, xliii.).

Sometimes sovereignty is defined as the organized or general will of the community (Combothecra, *Conception juridique de l'état*, p. 96). "Sovereignty is the organized will of an organized independent community. . . . The kings and parliaments who serve, as its vehicles." "Sovereignty resides in the community" (Woodrow Wilson, p. 1448). The same theory is often expressed by saying that the majority in a community, or a particular group, in fact, rules (Guizot, *Representative Government*, i. 167). This was the doctrine of the French Revolution. "Sachez que vous êtes rois et plus des rois," said a revolutionary orator cited by Taine. It was the language of the founders of the American constitution and contemporary political writers; the language, for example, of Paine: "In republics such as there are established in America the sovereign power, or the power over which there is no control and which controls all others, remains where nature placed it—in the people" (*Dissertations on Government*, i.6).

The same theory assumes a more subtle form, especially in the writings of Hegelians. Sovereignty is with them a term descriptive of the real will of the community, which is not necessarily that of the majority. "If the sovereign power is to be understood in this fuller, less abstract sense, if we mean by it the real determinant of the habitual obedience of the people, we must look for its sources much more widely and deeply than the analytical jurists do; it can no longer be said to reside in a determinate person or persons, but in that impalpable congeries of the hopes and fears of a people bound together by common interest and sympathy, which we call the common will" (Green's *Works*, 2. 404). "Though it may be misleading to speak of the general will as anywhere, either actually or properly, sovereign . . . yet it is true that the institutions of political society are an expression of, and are maintained by, the general will" (2. 409).

Sovereignty is used in a further sense when Plato and Aristotle speak of the sovereignty of the laws (*Laws*, 4. 715; *Politics*, 4. 4; 3. 15). Thus Plato remarks: "I see that the state in which the law is above the rulers, and the rulers are the inferiors of the law, has salvation." (See also Gierke, *Genossenschaftsrecht*, 3. 8.) Even in medieval writers, such as Bracton, is found the notion that the king is subject to the laws: "Bracton knows of no sovereign in the Austinian sense, and distinctly denies to the royal authority the attribute of being incapable of legal limitation" (J. N. Figgis, *The Divine Right of Kings*, p. 13). We find the same expressed by many German jurists, *i.e.* the idea of a state which exists only in the law and for the law, and whose life is but by a legal order regulating public and private relationship (Gierke iii., x.).

Definitions of Sovereignty. Among the definitions of sovereignty may be quoted these: "That which decides in questions of war and peace, and of making or dissolving alliances, and about laws and capital punishment, and exiles and fines, and audit of accounts and examinations of administrators after their term of office" (Aristotle, *Politics*, 4. 4. 3). "Suprematum illi tribuo qui non tantum domi subditos manu militari regit, sed et qui exercitum extra fines ducere et armis, foederibus, legationibus, ac caeteris juris gentium functionibus aliquid momenti ad rerum Europae generalium summam conferre potest" (Leibnitz, *Opera*, 4. 333). "La souveraineté est celle qui sert à exprimer l'indépendance d'un état aussi bien à l'intérieur qu'à l'extérieur" (F. de Martens, *Traité du droit international*, translated by A. Léo, 1883, i. 378). "L'indépendance complète qui peut se manifester à deux points de vue; l'un extérieur, l'autre intérieur" (Frentz Despagnet, *Droit international public*, 1894, p. 80). "Sovereignty as applied to states imports the supreme, absolute, uncontrollable power by which any state is governed" (T. M. Cooley, *Constitutional Limitations*, p. 1). "Social control, manifesting itself in the authoritative organization of society as the state, and acting through the organs of government, is sovereignty" (Giddings, *Elements of Sociology*, p. 217). The sovereign is "Absolut unabhängig und nur durch sich selbst beschränkt und beschränkbar" (Zorn, *Völkerrecht*, p. 4. See the collection of definitions in *Der Souveranitätsbegriff im Bodin*, &c., by Dr Adolf Dock (1897), p. 6, and in *La Conception juridique de l'état*, by Combothecra, p. 90). Many of these definitions describe an ideal state of things rather than realities. Some of the definitions would apply to the authority of powerful religious bodies in certain periods of history, or of illegal associations, such as the Mafia, which have terrorized the community.

Territorial sovereignty is used in a variety of senses. Often the phrase is the equivalent of sovereignty. It may mean a state of things such as existed in the middle ages, in which ownership and sovereignty were not clearly separated: when he who was owner had sovereign rights incident thereto, or, as it was sometimes phrased, when sovereignty inhered in the territory, when the king was the supreme landowner (Maine, *Ancient Law*, p. 106; Figgis, pp. 11, 14); when all political power exhibited proprietary traits, and was incident to the ownership of land (Maitland, *Township and Borough*, p. 31). Territorial sovereignty is thus defined by Leibnitz: "Superioritatem territorialem in summo subditos coercendi jure consistere" (*Opera*, 4. 358. See Laband, 1. c. 8).

Nature of Sovereignty. Certain propositions are often stated with respect to sovereignty. One of them, stated by Rousseau (*Du Contrat social*, 2. c. 2), is that it is indivisible: a proposition true in the sense that in regard to the same matters at the same time there cannot be two sovereigns, but not true in the sense in which it has often been employed, namely, that in the last analysis of society there are some persons or person who control all conduct and are habitually obeyed as to all matters. Rather we may say with Maine, "Sovereignty is divisible, but independence is not." To hold sovereignty not to be divisible is for juridical purposes not a working theory; states part, permanently or temporarily, with few or many of the rights and powers comprehended in sovereignty; to speak of it as undivided in the case of Crete, Egypt or Tibet is to do violence to facts.

A frequent deduction from the theory of the indivisibility of sovereignty is that there cannot be double allegiance; in other words, no one can be the subject of two states. This deduction is not in fact true. With the existing differences in the laws of modern states as to nationality, persons may be, and are, subjects of two or more states. In the native states in India there may be said to be double allegiance. C. L. Tupper, in his *Our Indian Protectorate*, refers to "the double allegiance of the subjects of native states" in India; and he explains that the native rulers are themselves subject to the Indian government. "For all purposes of our relation with powers the subjects of Indian native states must be regarded as subjects of Her Majesty" (*Our Indian Protectorate*, 1893, p. 353). Such double allegiance is apt to exist in times of transition from one sovereignty to another; for example, in the 18th century, in the British possessions in India, the Mogul was said to exercise a personal sovereignty. As Sir William Scott remarked in the *Indian Chief*, 3 C. Rob. 22, it hardly existed otherwise than as a phantom: the actual authority to be obeyed was exercised by the East India Company. The natives of protected states owe not only allegiance to them, but also certain duties, ill defined, to the protecting state.

Another deduction from the same proposition is that any corporation or private body which appears to exercise sovereign powers together with the state does so only by delegation. This theory is thus stated by Burke (*Works*, 7. 289) with reference to the East India Company: "The East India Company itself acts under two very dissimilar sorts of power, derived from two sources very remote from each other. The first source of its power is under charters which the Crown of Great Britain was authorized by act of parliament to grant, the other is from several charters derived from the emperor of the Moguls .... As to those of the first description, it is from the British charters that they derive a capacity by which they are considered as a public body, or at all capable of any public function. . . . This being the root and origin of their power, renders them responsible to the party from whom all their immediate or consequential powers are derived."

A further proposition often stated with respect to sovereignty is that it is unlimited: a proposition which is not true of the legal or political sovereign. In all states are limits, more or less definite, to such powers, according to the character of the subjects and the relations of the state to foreign powers. Even despotism is tempered by assassination and the liability of revolution (Dicey, *Law of the Constitution*, 6th ed., p. 75). A third proposition, often expressed with respect to sovereignty, is that it cannot be alienated: a proposition thus stated by Rousseau: "Je dis que la souveraineté, n'étant que l'exercise de la volonté générale, ne peut jamais s'aliéner" (*Du Contrat social*, 2. 1; Figgis, p. 89).

According to one view, sovereignty is not the distinctive note of a state. Many communities usually regarded as true states do not possess it. There are sovereign and non-sovereign states; international law recognizing both. In the view of many writers sovereignty is not a necessary attribute of a state (Laband, *Das Staatsrecht des deutschen Reiches*, 1. 87; Jellinek, *Die Lehre von den Staatenverbindungen*, p. 37; Meyer, *Lehrbuch des deutschen Staatsrechtes*, p. 5; Ullmann, *Völkerrecht*, 29. See the contrary view presented by Professor Burgess, *Political Science or Constitutional Law*, i. 52; *Political Science Quarterly*, 3. 123; Georges Streit, *Revue de droit international*, 1900, p. 14). Any division or classification of states must be imperfect. The fact is that there may be an indefinite number of what Merignhac (i. 204) terms political "*collectivités secondaires*"; that the attributes summed up in sovereignty may be separated and divided in many ways; that there may be new forms of combinations between states or parts of states; and that their morphology is subject to no hard and fast rules.

Half Sovereign States. The phrase *half sovereign states* was invented by J. J. Moser to describe states possessing some of the attributes of sovereignty. Under this class are grouped very diverse communities. There are states which possess some attributes of sovereignty, but no others; states possessing internal autonomy, but not externally independent; states which are more or less under the influence of others. There are also states which have certain of the attributes of sovereignty, but are subject to servitudes or burthens imposed by treaty, usage, or force. Feudalism had a phraseology to express the varieties of fiefs which existed under it; modern international law has no generally-accepted terminology for the still greater variety of states which now exist. These varieties tend to multiply, and it is difficult to reduce them all to a few types. The theory that states are equal, and possess all the attributes of sovereignty, was never true. It is still more at variance with the facts in these days when a few great states predominate, and when the contact of western states with African and Asiatic states or communities gives rise to relations of dependence falling short of conquest. The division into federations, confederations and alliances is not complete. Jellinek has suggested this classification (*Die Lehre von den Staatenverbindungen*, p. 58): (*a*) Unorganized associations, including—(1) treaties; (2) occupation of the territory of one state and administration by another, as in Bosnia and Cyprus; (3) alliances; (4) protectorates, guarantees, perpetual neutrality; (5) *Der Staatenstaat*, the feudal state, of which Jellinek gives the Turkish Empire and the old Holy Roman Empire as examples. (*b*) Organized associations, including—(1) international commissions (*internationale Verwaltungsvereine*, such as international postal and telegraph unions, &c.); (2) the *Staatenbund* or confederation of states; (3) real unions of states as distinguished from personal; (4) the *Bundesstaat* or federal state.[1] Most of the existing varieties may be conveniently ranged in the following classes:—

1. States which have complete independence, complete autonomy, external and internal, and which are recognized in international law as sovereign states.

2. States which have complete external independence, but are more or less subject permanently to other states as to their internal affairs. Of this class there are now few examples. Perhaps, however, such states as permit, permanently or normally, of interference by others on behalf of certain classes of subjects may be so described. The general principle is that a treaty does not detract from sovereignty. As Jellinek expresses it. "Der Staatenvertrag bindet, aber er unterwirft nicht" (*Gesetz und Verordnung*, p. 205); or as Grotius (1. ch. 3, 22, 2) expresses it, "Nec regi aut populo jus demit summi imperii."

3. States which enjoy complete autonomy as to internal affairs, but which are more or less subject to other states as to foreign relations. Some writers would place in this category all states forming part of a true confederacy. It includes states which are united temporarily—cases of inorganic unity, to use Jellinek's expression. It includes also permanent alliances or organic unions. These are some examples:—

a. Protectorates and Suzerainties.—The status of certain states, such as Bulgaria and Rumania and the late South African Republic, were peculiar. Even before the independence of the two first-named states, they undoubtedly were for many purposes sovereign.

b. The unions between a superior and inferior state, *e.g.* the relations of the various states to the old Holy Roman Empire; the relations of the Ottoman Porte to its Christian provinces. In the middle ages the question was often mooted whether states subject to feudal superiors, or the states forming the empire, were sovereign. According to one common definition they were not: a true sovereign state was *universitas quae non superiorem recognoscit*. "Celui est absolument souverain qui ne rien tient après Dieu que de l'espée. S'il tient d'autrui il n'est plus souverain." The prevalent opinion, however, was that sovereignty was compatible with rights such as were possessed by the *Reich* over the princes of Germany; that there might be fiefs held in full sovereignty; and that vassal states, when subject only to "nude vassalage," were sovereign. That was the view of Grotius (1. 1. ch. 3, 23. 2), who holds that the *nexus feudalis* is consistent with summum imperium.

4. States which have, by treaty or otherwise, parted with some portion of their sovereignty and formed new political units: what Herbert Spencer calls "compound political heads," or, to use Austin's expression, "composite states." The most important examples of this class consist of federal or composite states which by treaty or otherwise have surrendered certain of their powers, or which have created a new state (Staatenbund). For many years one of the burning questions in the politics of the United States was the question whether the individual states of the Union remained sovereign. According to the theory of J. C. Calhoun, the states had entered into an agreement from which they might withdraw if its terms were broken, and they were sovereign. According to the theory expounded in the *Federalist*, the individual states did not, after the formation of the constitution, remain completely sovereign: they were left in possession of certain attributes of sovereignty, while others were lodged in the Federal government; while there existed many states, there was but one sovereign. Even if the origin was a compact or contract, after the "United States" were formed by a "constitutional act" there no longer existed a mere contractual relation: there existed a state to which all were subject, and which all must obey (von Stengel, *Staatenbund und Bundesstaat; Jahrbuch für Gesetzgebung*, 1898, p. 754; Cooley, *Principles of Constitutional Law*, pp. 21, 102). According to Austin: "In the case of a composite state or a supreme federal government, the several united governments of the several united societies together with a government common to these several societies, are jointly sovereign in each of these several societies and also in the larger society arising from the federal union, the several governments of the several united societies are jointly sovereign in each and all" (5th ed., vol. i. p. 258). In point of fact, there are fields of action in which A is sovereign, others in which B is sovereign, and certain others in which A and B are jointly or alternately sovereign. To take the American constitution, for example, the states are sovereign as to some matters, the Federal government as to others.

5. Another division includes anomalous cases, such as Cyprus or Bosnia, in which one government administers a country as to which another state retains certain powers, theoretically large.

6. The territories governed or administered by chartered companies form a class by themselves. Nominally such companies are the delegates of some states; in reality they act as if they were true sovereigns.

7. Two other classes may be mentioned: (*a*) cases of real union between states, *e.g.* that between Austria and Hungary; (*b*) personal unions, distinguished from the above-named forms—for example, the union of Great Britain and Hanover.

8. A small group consists of instances of *condominium* or arrangements similar thereto; for example, the arrangements as to the Samoa Islands from 1889 to 1899.

Size of State.

According to modern usage the appellation "sovereign state" belongs only to states of considerable size and population exercising without control the usual powers of a state, *e.g.* able to declare peace or war. Leibnitz, discussing this subject in his *Tractatus de jure suprematus* (*Opera*, 4. 362), says: "Itaque valde etiam dubito, an possit Reipublicae illi Italiae, quam vocant Sancti Marini oppidum, concedi suprematus, tametsi jure liberam esse nemo negat," a remark which would apply also to the republic of Andorra: "Illi tantum vocantur souverains ou potentats, qui territorium majus habent, exercitumque educere possunt; atque hoc demum illud est, quod ego voco suprematum, et Gallos quoque arbitror, cum de rebus ad jus gentium spectantibus, pace, bello, foederibus sermo est, et ipsi aliquos vocant souverains, eos non de urbibus liberis loqui, nec exiguorum territoriorum dominis, quae facile dives Mercator sibi emere potest, sed de majoribus illis potestatibus, quae bellum inferre, bellum sustinere, propria quodammodo vi stare, foedera pangere, rebus aliarum gentium cum auctoritate intervenire possunt" (4. 359).

With this view may be compared that of a writer in the *Law Magazine* (1899) xxv. 30, who argues that the republic of San Marino is a state in the full sense.

Colonies.

It is sometimes suggested that self-governing colonies are to be regarded as true states. Undoubtedly some of them can no longer be regarded as colonies in the old sense. The self-governing colonies forming part of the "multicellular British state," as F. W. Maitland describes it (*Political Theories of the Middle Ages*, p. x.), have an essentially "state-like character." If Liberia is a state, the same may surely be

[1] The distinction between the *Staatenbund* and the *Bundesstaat* is discussed in the articles CONFEDERATION and FEDERAL GOVERNMENT.

said of Canada. It is true the British colonies have not the power of declaring war or peace, or regulating the foreign policy of the empire; and the Crown may disallow a measure passed by the dominion parliament (J. G. Bourinot, *Constitution of Canada*, 1888, p. 75; A. H. F. Lefroy, *Legislative Power in Canada*, 244). Colonial legislatures are said to have delegated powers. It is more accurate to say that as to certain matters the legislature of the Canadian Dominion is sovereign, and as to certain others that it is not (Lefroy, 244; Quick and Garran, *Australian Commonwealth*, 328; Dicey, 106); and as to some matters they are in fact, if not in form, *universitates superiorem non recognoscentes* (Quick and Garran, 319); or that they are states in process of making. Occasionally the expression "subject of a colony" is now used (*Low* v. *Routledge*, L.R. 1 Ch. 42; Lefroy, *Legislative Power in Canada*, 329). It has been decided by the judicial committee of the Privy Council that the colonial legislatures are not mere delegates of the Imperial parliament (A. B. Keith, *Responsible Government in the Colonies*, p. 81). At all events, the self-governing colonies may be classed as "half sovereign states" or "quasi-sovereign."

Attributes of Sovereignty.

Many attempts have been made to enumerate the attributes of sovereignty, *i.e.* the regalia, prerogatives, &c., as they were called. For example, Bodin gives a list of the properties of *majestas* or sovereignty: (*a*) "Legem universis, &c., singulis civibus dare posse; (*b*) bellum indicere aut pacem inire; (*c*) to appoint and change magistrates; (*d*) power of final appeal; (*e*) power of pardon; (*f*) raising revenue; (*g*) coining money" (*De republica*, vol. i. ch. 10). Leibnitz, with the middle ages in view, divides the attributes or faculties into two classes: *regalia majora* and *regalia minora*. Hobbes (*Leviathan*), analysing these attributes, enumerates twelve attributes. "These," he says, "are the marks which make the essence of sovereignty, and which are the marks whereby a man may discover in what man, or assembly of men, the sovereign power is placed or resideth." He also describes them as "inseparable rights." Bluntschli (*Allgemeine Staatslehre*, i. 575) enumerates these attributes: (*a*) right of recognition of *majestas*; (*b*) independence; (*c*) power to determine constitution; (*d*) right of legislation; (*e*) action through deposed organs; (*f*) irresponsibility. All of these enumerations are open to the objection that they merely describe the action of the state at a particular time, or indicate a theory of what an ideal state should be.

AUTHORITIES.—The literature of the subject is immense; every book on political science, from *Republic* of Plato and the *Politics* of Aristotle, has dealt with or touched sovereignty. A few of the chief modern works are: J. C. Bluntschli, *Allgemeine Staatslehre* (Munich, 1852); Otto Gierke, *Das deutsche Genossenschaftsrecht* (Berlin, 1863–1881); J. Austin, *Lectures on Jurisprudence* (3rd ed., London, 1869); Sir H. Maine, "Minute on the Kāthiāwār States" (1864; printed in *Life and Speeches*, p. 320) and *Early History of Institutions* (1875); P. Laband, *Staatsrecht des deutschen Reiches* (Freiburg-im-Breisgau and Tübingen, 1876); R. von Mohl, *Encyclopädie der Staatswissenschaften* (2nd ed., Tübingen, 1872); O. Gierke, *Johannes Althusius* (Breslau, 1880); G. Jellinek, *Die Lehre von den Staatsverbindungen* (Vienna, 1882); G. Meyer, *Lehrbuch des deutschen Staatsrechts* (Leipzig, 1878); H. Rosin, *Souveranitätstaat* (1883); K. Gareis, *Allgemeines Staatsrecht* (1882); T. M. Cooley, *Constitutional Limitations* (6th ed., 1890); Jellinek, *Ueber Staatsfragmente* (1896); J. B. Westerkamp, *Staatenbund und Bundesstaat* (Leipzig, 1892); J. R. Green's *Works* (London, 1892); W. W. Fowler, *City State of the Greeks and Romans* (London, 1893); Salomon, *L'Occupation des territoires sans maîtres* (Paris, 1896); A. V. Dicey, *Law of the Constitution* (6th ed., 1902); X. Combothecra, *La Conception juridique de l'état* (1899); H. Rehm, *Allgemeine Staatslehre* 1899); Franklin H. Giddings, *Principles of Sociology* (3rd ed., New York, 1899); J. W. Burgess, *Political Science and Constitutional Law* (Boston, 1899); C. E. Merriam, *History of the Theory of Sovereignty since Rousseau* (New York, 1900); J. Bryce, *Studies in History and Jurisprudence* (2. Essay x. 1901); K. Bornhak, *Einseitige Abhangigkeitsverhältnisse unter den modernen Staaten* (1896); W. W. Willoughby, *The Nature of the State* (New York, 1896); Clauss, *Die Lehre von den Staatsdienstbarkeiten* (1894); Bosanquet, *The Philosophical Theory of the State* (1899); J. B. Moore, *Digest of International Law* (Washington, 1906), i. 18 seq.; "Notes on Sovereignty," *American Journal of International Law* 1907), i. 105; W. B. Keith, *Responsible Government in the Colonies* (1909); T. Baty, *International Law* (1909). (J. M.)

SOWAR (Hind. and Pers. *suwar*, a horseman), the name in Anglo-Indian usage for a horse-soldier belonging to the cavalry troops of the native armies of British India and the feudatory states. It is also used more specifically of a mounted orderly, escort or guard.

SOWERBY, JAMES (1757–1822), English natural-history artist, was born in London on the 21st of March 1757. He became a student at the Royal Academy, and subsequently taught drawing, but soon applied his art to the illustration of botanical and conchological works, and became distinguished by the publication of his *English Botany* (36 vols., 1790–1814), and *British Mineralogy* (5 vols., 1804–1817). He likewise planned and carried out for a number of years the classic geological work intended to describe and illustrate the British fossils, and entitled *The Mineral Conchology of Great Britain* (7 vols., 1812–1846). This was issued in parts, with the assistance first of his elder son, J. de C. Sowerby, and, after J. Sowerby's death (Oct. 25, 1822), of his second son, G. B. Sowerby, both the sons being themselves expert palaeontologists. The Sowerby collection, consisting of about 5000 fossils, was purchased by the British Museum in 1860.

The elder son, JAMES DE CARLE SOWERBY (1787–1871), was in 1838 one of the founders of the Royal Botanic Society, and was its secretary for thirty years. He supplied the plates and part of the text to the *Supplement to English Botany* (4 vols., 1831–1849); but his most important work related to palaeontology, as he identified and in many cases described the invertebrate fossils for papers by Buckland, Sedgwick, Fitton, Murchison and others in the *Transactions of the Geological Society of London.*

The younger son, GEORGE BRETTINGHAM SOWERBY (1788–1854) was author of *The Genera of Recent and Fossil Shells* (1820–1825), and one of the editors of the *Zoological Journal* (1825–1826). His son, G. B. SOWERBY (1812–1884), author of the *Conchological Manual* (1839; 4th ed., 1852), and grandson G. B. SOWERBY (*b.* 1843), a distinguished student of the Mollusca, inherited the family talent for natural history.

SOWERBY BRIDGE, an urban district in the Sowerby parliamentary division of the West Riding of Yorkshire, England, 3 m. S.W. of Halifax by the Lancashire & Yorkshire railway. It is situated on both sides of the river Calder, at the termination of the Rochdale canal. Christ Church, dating from 1526, was rebuilt in 1819. The town is almost entirely a growth of the second half of the 19th century. It possesses worsted and cotton mills, iron works, dye works and chemical works. The separate urban district of Sowerby adjoins to the south-west. Pop. (1901), Sowerby Bridge, 11,477; Sowerby, 3653.

SOWING (from "to sow," O. Eng. *sāwan*, cf. Du. *zaaijen*, Ger. *säen*, &c.; the root is seen in Lat. *serere*, cf. "seed"), in agriculture, the planting of seed for the raising of crops. The scattering of seed by hand is the simplest and oldest method of delivering seed to the earth, and is still preferred by some farmers and in certain circumstances. The sower carries the receptacle for the seed, a zinc "seed-lip," seed-sheet or basket, slung over his shoulder, and walking up and down the ridges of the field scatters handfuls of grain with a semicircular sweep of the arm across the body. The "casts" must not overlap too much, the seed must not fall more thickly at one point of the cast than at another, and the standard of seeding per acre must be rigidly adhered to; hence manual-sowing demands considerable skill and experience. It is still preferred in some districts for the sowing of corn crops; and in some cases the plough is followed by a furrow-presser, the seed falling into the hollows made by it, though under ordinary circumstances the face of the field as left in "seams" by the furrow-slices from the plough is in a suitable condition for broadcasting. So well, indeed, is the ploughing done in many countries that broadcasting gives perfectly good results, and broadcasting machines reaching up to 15 ft. wide are in common use in place of hand-sowing, as these get over the ground more quickly and deposit the seed more regularly than an ordinary workman does by hand.

It was long recognized that the precision which is of the essence of good sowing could be better attained by mechanical means, and as early as 1662 a sowing-machine was invented by Joseph Locatelli in Carinthia. In England the early history of mechanical sowing is chiefly connected with the name of Jethro Tull, who about 1730 invented the corn-drill.[1] Cooke's drill brought out in 1783 was the definite precursor of the modern drill. The drill, besides depositing the seed at a uniform depth, sows it in parallel rows at equal distances from one another and thus makes possible the use of the horse hoe and facilitates the suppression of weeds amongst growing crops, the latter advantage being specially marked in the case of root crops. The "cup-feed" and the "force-feed" are the commonest and most generally useful types. The cup-drill consists of a long box carried upon wheels and divided diagonally into two sections by a partition. The forward section contains the seed which drops through apertures, the size of which can be regulated by slides, to the bottom section. A spindle geared to the ground-wheels by cogs passes longitudinally through the centre of this section and carries disks, round the rims of which are fitted small cups. As the horses pull the drill forward, the spindle and disks revolve and the cups scoop up the seed and pour it into the funnels; thence it proceeds down a series of tubes or "spouts" and drops into shallow furrows traced by small coulters travelling immediately in front of the streams of seed. The coulters can be raised or lowered by levers and are kept down to their work by weights or pressers, which can be regulated according as deep or shallow sowing is required.

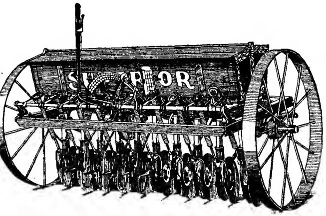

FIG. 1.—Rear view of Corn and Fertilizer Single Disk Drill.

In the force-feed type of drill the seed falls through apertures in the bottom of the seed-hopper into funnels, through which extends a shaft carrying bowl-shaped wheels, one for each (fig. 1). These wheels are either spirally-grooved inside or else cogged and serve to feed the seed regularly into the tubes. Instead of coulters, the drill is often fitted with shoes or revolving disks, similar in action to those of the disk-harrow. The tooth and brush pinion, the perforated disk and the chain feed drills, are other types differentiated according to the method by which the seed is "fed" from the hopper and the kind of crop being sown.

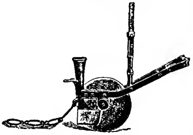

FIG. 2.—Disk Coulter.

Liquid-manure drills distribute chemical manure mixed with water and are often fitted with a seed-box for root seeds, the manure and the seed being deposited through the same spout. Drills are also made in which dry fertilizers may be deposited with the seed in a similar manner.

The wheelbarrow seeder, a long box pierced with openings and carried transversely on a skeleton wheelbarrow, is used for sowing grass seed.

[1] The machine devised by Josiah Worlidge about 1669 was ineffective in practice and differed totally in structure from that of Tull.

In the United States the maize or Indian-corn crop exceeds all others in value, and machines used in planting and handling this crop are of great importance. Corn (maize) is sometimes listed or planted in a continuous row like wheat, and for this purpose a machine known as a lister is employed.

In its general construction this machine is a sulky plough, having a double mould-board, which turns the furrow in both directions. Immediately behind the plough is a sub-soiler for deepening the furrow and penetrating to the moist soil below the surface. A seed-box is mounted on the plough beam, and is provided with a feed-plate operated by a shaft geared to one of the wheels. The seed is delivered to the furrow in rear of the mould-boards and covered by two shovels fixed behind which turn the soil back into the furrow.

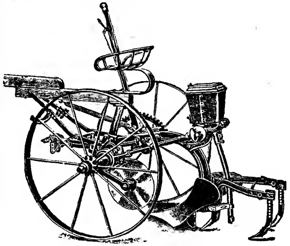

FIG. 3.—Maize Lister.

It is, however, more common to plant maize in hills, which are spaced equally from each other and form rows in both directions, so that a cultivator may be driven between them. This work is done by a machine called a check-row corn planter.

In using the corn planter, a wire, having buttons attached thereto, at intervals corresponding to the distance between the hills, is first stretched across the field and anchored at its ends. This wire is then placed upon the guide rollers at the side of the machine and passes between the jaws of a forked lever, which is connected at its other end with a rock-shaft passing across the machine and serving to oscillate a feed-plate in the bottom of each seed-hopper. As the buttons on the check-wire strike the forked lever, the latter is drawn to the rear and causes the feed-plate to drop the seed through the tubes into the open space between the plates of the furrowing shoe. A reel at the rear of the machine is used to take up the check-wire as the planter progresses.

In another corn planter the check-wire is dispensed with, and the machine is provided with a shaft carrying two reels, the blades of which are at a distance apart equal to the distance between the hills of corn, and thus measure the intervals at which the corn is to be dropped. A rod, extending from the side of the machine, and carrying a small wheel, marks the next row and serves as a guide to the driver.

See J. B. Davidson and L. W. Chase, *Farm Machinery and Farm Motors*, p. 132 (New York, 1908).

SOYER, ALEXIS BENOÎT (1809–1858), French culinary artist, was born at Meaux-en-Brie, France, in October 1809. After five years' apprenticeship as a cook near Versailles, he was engaged by a well-known Paris restaurateur, and soon became chief cook. Leaving France at the revolution of 1830, he went to London and joined his brother in the kitchen of the duke of Cambridge. Subsequently he was cook in several noblemen's kitchens, and in 1837 was made chef to the Reform Club, London. In 1847, having written several letters to the press on the famine in Ireland, he was commissioned by the government to establish kitchens in Dublin. In 1850 he resigned his position at the Reform Club, and the following year opened Gore House, Kensington, as a restaurant, but this venture did not prove a success. In 1855 he offered, through the medium of *The Times*, to proceed at his own expense to the Crimea and advise on the cooking for the British army there. His services were accepted by the government. On returning from the front he lectured at the United Service Institution on cooking for the services, and reformed the dietary of the military hospitals, and of the emigration commissioners. He died in London on the 5th of August 1858. Soyer was the inventor of an army cooking wagon, and the author of a variety of cookery books. His wife, Elizabeth Emma Soyer, achieved considerable popularity as a painter, chiefly of portraits.

SOZOMEN, the name of a famous 5th-century church historian. Hermias Salamanes (Salaminius) Sozomenus (*c.* 400–443) came of a wealthy family of Palestine, and it is exceedingly probable that he himself was born and brought up there—in Gaza or the neighbourhood. What he has to tell us of the history of South Palestine was derived from oral tradition. His grandfather, he tells us, lived at Bethel, near Gaza, and became a Christian, probably under Constantius, through the influence of Hilarion, who had miraculously healed an acquaintance of the grandfather, one Alaphion. Both men with their families became zealous Christians. The historian's grandfather became within his own circle a highly esteemed interpreter of Scripture, and held fast his profession even in the time of Julian. The descendants of the wealthy Alaphion founded churches and convents in the district, and were particularly active in promoting monasticism. Sozomen himself had conversed with one of these, a very old man. He tells us that he was brought up under monkish influences and his history bears him out. As a man he retained the impressions of his youth, and his great work was to be also a monument of his reverence for the monks in general and for the disciples of Hilarion in particular. After studying law in Beirūt he settled down as an advocate in Constantinople, where he wrote his Ἐκκλησιαστικὴ Ἱστορία about the year 440. The nine books of which it is composed begin with Constantine (323) and come down to the death of Honorius (423); but according to his own statement he intended to continue it as far as the year 439 (see the Dedication of the work). From Sozomen himself (iv. 17), and statements of his excerptors Nicephorus and Theophanes, it can be made out that the work did actually come down to that year, and that consequently it has reached us only in a mutilated condition, at least half a book being wanting (Güldenpenning, *Theodoros von Kyrrhos*, p. 12 seq., holds that Sozomen himself suppressed the end of his work). A flattering and bombastic dedication to Theodosius II. is prefixed. When compared with the history of the ecclesiastical historian Socrates (*q.v.*), it is plainly seen to be a plagiarism from that work, and that on a large scale. Some three-fourths of the materials, essentially in the same arrangement, have been appropriated from his predecessor without his being named, the other sources to which Sozomen was indebted being expressly cited. But it is to his credit that he has been himself at the trouble to refer to the principal sources used by Socrates (Rufinus, Eusebius, Athanasius, Sabinus, the collections of epistles, Palladius), and has not unfrequently supplemented Socrates from them; and also that he has used some new authorities, in particular sources relating to Christianity in Persia and to the history of Arianism, monkish histories, the *Vita Martini* of Sulpicius, and works of Hilarius. The whole of the ninth book is drawn from Olympiodorus.

It is probable that Sozomen did not approve of Socrates's freer attitude towards Greek science, and that he wished to present a picture in which the clergy should be still further glorified and monasticism brought into still stronger prominence. In Sozomen everything is a shade more ecclesiastical —but only a shade—than in Socrates. Perhaps also he wrote for the monks in Palestine, and could be sure that the work of his predecessor would not be known.

Sozomen is an inferior Socrates. What in Socrates still betrays some vestiges of historical sense, his moderation, his reserve in questions of dogma, his impartiality—all this is wanting in Sozomen. In many cases he has repeated the exact words of Socrates, but with him they have passed almost into mere phrases. The chronological scrupulosity of the earlier writer has made no impression on his follower; he has either wholly omitted or inaccurately repeated the chronological data. He writes more wordily and diffusely. In his characterizations of persons, borrowed from Socrates, he is more dull and colourless. After Socrates he has indeed repeated the caution not to be too rash in discerning the finger of God; but his way of looking at things is throughout mean and rustic. Two souls inhabit his book; one, the better, is borrowed from Socrates; another, the worse, is his own. Evidence of a boundless credulity with regard to all sorts of monkish fables is to be met with everywhere. It must, however, be noted that for the period from Theodosius I. onward he has emancipated himself more fully from Socrates and has followed Olympiodorus in part, partly also oral tradition; and here his statements possess greater value.

Sozomen also wrote an *Epitome of History* from the Ascension of Christ to the defeat of Licinius (323) which is not now extant (see his *History*, i. 1).

For bibliography see the article on the church historian, SOCRATES. Most of the editions and discussions named there cover Sozomen as well (the volume of Hussey's edition containing Sozomen appeared in 1860). The latest English translation, revised by Hartranft, is published in the Nicene and Post-Nicene Fathers, 2nd series, vol. ii. In addition see Nolte in the *Tübing. Quartalschr.* (1861), p. 417 sqq.; C. de Boor, "Zur Kenntniss der Handschriften der Griech. Kirchenhistoriker," in *Zeitschrift für Kirchengeschichte*, vi. 478 sqq.; Sarrazin, "De Sozomeni historia num integra sit," in the *Commentationes philologae jenenses*, i. 165 sqq.; Rosenstein, "Krit. Untersuchungen über d. Verhältniss zwischen Olympiodor, Zosimus und Sozomen," in *Forsch. z. deutschen Gesch.*, vol. i.; Batiffol, "Sozomène et Sabinos," in *Byzant. Zeitschr.* vii. 265 sqq.

(A. HA.; A. C. McG.)

SPA, a town of Belgium, lying less than 20 m. S.E. of Liége and in the same province, famous for its mineral springs, which are reputed to be the oldest known in Europe, having been first discovered in 1326. They are supposed to have given the common name of "spa" to such resorts. The town is situated 850 ft. above sea-level and the heights above the valley reach 1100 ft. In the 18th century it was the most fashionable resort in Europe for the medicinal use of such waters, being visited by Peter the Great of Russia, Gustavus III. of Sweden, and Joseph II. of Austria. In 1807 much of the town was burned down, while the principal buildings, the Casino and the Pouhon, are quite modern. Spa has not held its own with its many French and German rivals, but it still attracts about 20,000 visitors annually. Pop. (1904), 7759.

SPACE AND TIME, in philosophy. The metaphysical problems connected with Space and Time are so similar and have been so closely conjoined in the history of thought that they may well be treated together. They are clearly distinguishable from the psychological, which relate to the modes whereby our spatial and temporal conceptions have been formed and to the analysis of the materials of which they are composed (see PSYCHOLOGY). In an exhaustive treatment of Space and Time by far the largest share of the work rests with the psychologist. The business of the metaphysician is to determine what reality outside our minds corresponds to our temporal and spatial conceptions.

The first tendency of thought is to treat Space and Time as having objective existence in the same way as the ordinary things that compose our world, and this we may call the *objective* method. Simple as it appears to be, it discloses formidable difficulties, which may be illustrated by a consideration of Newton's famous account of "absolute, true and mathematical time" as something which "in itself and from its own nature flows equally" and with no liability to change. Now, if mathematical time as thus described is merely an abstraction used to facilitate mathematical calculations, no objection can be taken to it. But if Newton meant to assert that Time is a flowing stream no less actual than the Thames, his assertion is open to fatal objections. All admittedly real streams, such as the Thames, have a definite beginning and an ending. But where is the source of Time and where is its outlet? Every real stream has boundaries at its sides. What are the boundaries of Time? Every real stream has certain definite qualities: water is rather heavy and translucent, and produces certain effects upon bodies plunged into it. What are the specific qualities of Time? How are things in time affected by their immersion in time so as to be different from things not in time? And if it be asserted that time has such specific qualities, by what senses do we perceive them? We may fairly assume that none of these questions can be answered intelligibly by one who holds the Newtonian position. And thus we are justified in the conclusion that time is not a real stream at all, but something which is said to behave like a stream only in some metaphorical sense. Similar difficulties arise if we try to attribute a like objective reality to Space. We can imagine no boundaries to Space; it seems to have no active specific qualities and we have no sense-organ for perceiving it.

The thinkers of antiquity saw these difficulties without solving them. Their whole treatment of philosophic problems was objective; and, so long as Space and Time are treated objectively, not much can be done with them. Plato has great difficulty in explaining the relation between Space and his Ideas: Aristotle contents himself with defining space as " the first unmoved limit of the containing body, " a definition which helps us very little: nor do we get more light from later Greek philosophy. As to Time, there was always a tendency in Greek thought to treat it as in some sense unreal. Time was seen to be intimately connected with change, and it was just their liability to change that made ordinary mundane things unreal, as contrasted with the unchanging steadfastness of the Platonic Ideas. And the pantheistic One-and-All of Plotinus is plainly incompatible with the reality of Time. In all pantheistic systems Time belongs to mundane existence and Eternity to the transcendent Reality.

Modern philosophy is distinguished from ancient mainly by its greater subjectivity; and thus it was not long after the rise of modern philosophy that thinkers began to turn to the *subjective* method of explaining Space and Time, that is, to regard them as real only to our minds. Its use begins effectively with Berkeley, though prepared for to some extent by earlier writers such as Hobbes. Berkeley's treatment is most definitely clear in the case of Space; for his attack upon materialism made it necessary for him to affirm the ideality of Space as well as of Matter. But he takes a similar line of argument with Time, declaring it to be nothing but the succession of ideas. The merit of the subjective method was that it made men see the importance of psychology. If Space and Time exist only in the human mind we must analyse the human mind to explain them. The work of the English psychologists such as the Mills and Bain attaches itself to subjectivist principles.

A distinct epoch in the history of the subject was made by the work of Kant, whose solution of the problems may be classed as *transcendental*. He argued that Space and Time are not given by experience, but are rather conditions of all our experience, being in his terminology a priori, that is, supplied by the mind from its own inward resources. They do not belong to things-in-themselves, but to things-as-we-know-them, or phenomena. Their validity consists in the fact that all men have them and that they are absolutely necessary conditions of human intelligence. As he expresses it from his peculiar point of view, Space is the form of outer sense, Time of inner sense.

The prevalence of German philosophy in Great Britain during the last quarter of the 19th century has given these Kantian principles a great currency, interrupting the more truly characteristic psychological tendency of British thought. That prevalence is now passing away. No one now holds the full Kantian position; which, in the case of Space, is refuted by the simple consideration that our spatial conceptions depend upon our sensuous perceptive powers; and that, consequently, the spatial conceptions of the blind, for example, are quite different from those of ordinary men. If Kant is right, and Space is a pure form unaffected by all specific differences of content, it would follow that a man born with one sense only, say that of taste, would have the same space-conception as the rest of us; a conclusion too plainly absurd to need refutation. What an apriorist can still maintain is that in our conception of Space and Time there are elements which cannot be explained by the psychologist as having developed out of anything else, and must therefore be regarded as innate endowments of the mind. This is a position not unreasonable in itself, and one, at least, which does not interfere with the detailed work of the psychologist.

The way with these problems which commends itself to the present writer and seems fully in harmony with the general tone of contemporary thinking may, if a distinctive catchword be desired, be termed the *humanist* method. By this is meant that the study of the human mind comes first; that we put no metaphysical questions till we have learnt what the psychologist has to teach us; and that in our explanations of metaphysical realities we should be as anthropomorphic as possible. In the case of Space this leads to a result which is largely negative. When we ask what objective reality corresponds to our conception of Space, the answer must be analogous to that which we give respecting the various sensible qualities of the external world. We cannot suppose that Colour, for example, exists objectively as we experience it; evidently it is altogether relative to the organs of vision which we happen to possess. But we must believe that the objective world has a quality in some way correspondent to the quality of Colour. So with Space. Space as we know it is altogether relative to our tactual, muscular and visual powers of perception. But the fact that our spatial perceptions and conceptions enable us to deal successfully with objects requires us to believe that the objective world has an arrangement of its own corresponding in some way to spatial arrangement, though we are unable to imagine what it can be. Space cannot be objectively real, because of the difficulties disclosed above in the criticism of the " objective " method, and we are unable to put anything definite in its place. With Time the case is somewhat different. Our conception of Time is based on our experience of Change, combined with memory and anticipation. Now Change is an experience which we feel directly in our personal consciousness: consciousness is not spatial, but it is mutable. This direct experience is a guarantee of the realness of Change, and justifies us in attributing it in some degree to ultimate objective reality.

See S. H. Hodgson, *Space and Time*; H. Bergson, *Essai sur les données immédiates de la conscience*; J. E. MacTaggart, *Studies in the Hegelian Dialectic.* (H. St.)

SPADE, a tool for digging and loosening the soil; together with the fork it forms one of the chief implements wielded by the hand in agriculture and horticulture. Its typical shape is a broad flat blade of iron with a sharp lower edge, straight or curved, the upper edge on either side of the handle affording space for the foot of the digger, which drives it into the ground; the wooden handle terminates in a cross-piece, usually forming a kind of loop for the hand. The word in O.Eng. is *spaedu*, cognate forms being Du., Swed. and Dan. *spade*, Ger. *Spaten*; it is derived from the Gr. σπάθη, a broad blade of wood or metal, and so used of the blade of an oar or sword. This was latinized as *spatha*, and used of a broad paddle for stirring liquid, of a piece of wood used by weavers for driving home the woof, and particularly of a broad two-edged sword without a point. The Spanish playing cards had " swords " for the suit which we know as " spades," and the suit was called *espada* (see Cards, Playing).

SPAGNA, LO (d. *-c.* 1529), the usual designation (due to his Spanish origin) of the Italian painter Giovanni di Pietro, one of the chief followers of Perugino. The famous " Sposalizio "—marriage of Joseph and Mary—in the Caen museum, formerly attributed to Perugino (*q.v.*), is now credited to Lo Spagna. Nothing whatever is known of his early life, or how he became a member of the Perugian school. There is a marked absence of individuality about his style, which seems like an imitation of the earliest manner of Raphael and that of Pinturicchio in a weaker and less virile form. The chief of his numerous panel paintings are the " Nativity," in the Vatican, and the " Adoration of the Magi," at Berlin. In 1510 Lo Spagna executed many frescoes at Todi, and in 1512 several other mural paintings in and near Trevi. His most important works were frescoes at Assisi and Spoleto, of which some exist in good preservation. He received the freedom of the city of Spoleto in 1516, as a reward for his work there. Lo Spagna's frescoes reach a much higher standard of merit than his panel pictures. The museum of the Capitol in Rome now possesses a very beautiful series of life-sized fresco figures by him, representing Apollo and the

Nine Muses. Lo Spagna was alive in 1528, but he appears to have died before 1530, as in that year a pupil of his named Doni completed a fresco in S. Jacopo, near Spoleto, which Lo Spagna had begun.

SPAHIS (in Persian *Sipari*, meaning warriors, and synonymous with *Sepoy*) originally the holders of fiefs in Central Asia who yielded personal military service to their superior chief. In time the term came to be applied to the soldiery furnished in their own stead. A similar institution existed in Turkey, and the "Spahis" were the light irregular cavalry which from the time of Sultan Amurath I. (1326) down to the beginning of the 19th century formed the flower of the Turkish army; at one period they are estimated to have numbered 130,000. "Spahis" is the term now applied to certain native cavalry regiments in Algiers and Tunis, officered by Frenchmen.

SPAIN (*España*), a kingdom in the extreme south-west of Europe, comprising about eleven-thirteenths of the Iberian Peninsula, in addition to the Balearic Islands, the Canary Islands, and the fortified station of Ceuta, on the Moroccan coast opposite to Gibraltar. Each of the two island groups forms one of the forty-nine provinces of the kingdom, although only the first named belongs geographically to Spain. Ceuta is included in the province of Cadiz. In 1900 the kingdom (exclusive of its colonies) had a population of 18,607,674, and a total area of 194,700 sq. m. It is thus rather more than twice the size of Great Britain, nearly 50,000 sq. m. larger than Japan, and nearly 85,000 sq. m. larger than Italy and Sicily. Exclusive of the Canaries its area is 191,893 sq. m. On all sides except that of Portugal the boundaries of continental Spain are natural, the Peninsula being separated from France by the Pyrenees and on every other side being surrounded by the sea. On the side of Portugal a tract of inhospitable country led originally to the separation between the two kingdoms, inasmuch as it caused the reconquest of the comparatively populous maritime tracts from the Moors to be carried out independently of that of the eastern kingdoms, which were also well peopled. The absence of any such means of intercommunication as navigable rivers afford has favoured the continuance of this isolation. The precise line of the western frontier is formed for a considerable length by portions of the chief rivers or by small tributaries, and on the north (between Portugal and Galicia) it is determined to a large extent by small mountain ranges. The British rock of Gibraltar, in the extreme south of the peninsula, is separated from Spain by a low isthmus known as the Neutral Ground.

Colonial Possessions. By the relinquishment of Cuba and the cession of Porto Rico, the Philippine and Sulu Islands, and Guam, the largest of the Ladrones, to the United States, as a consequence of the war of 1898, and of the remaining Ladrone or Marianne Islands, together with the Caroline and Pelew Islands, to Germany by a treaty of the 8th of February 1899, the colonial possessions of Spain were greatly reduced. Apart from Ceuta, Spain possesses on the Moroccan seaboard Melilla, Alhucemas, Peñon de la Gomera, Ifni, and the Chaffarinas islets. Besides these isolated posts Spain holds Rio de Oro, a stretch of the Saharan coast, and its hinterland lying between Morocco and French West Africa; the Muni River Settlements or Spanish Guinea, situated between French Congo and the German colony of Cameroon; Fernando Po, Annobon, Corisco and other islands in the Gulf of Guinea. Spain has given to France the right of pre-emption over any of her West African colonies.

I.—General Survey of the Spanish Kingdom

Physical Features.—The coast-line on the north and north-west is everywhere steep and rocky. On the north there are numerous small indentations, many of which form convenient harbours, although the current flowing along the coast from the west often leaves in the stiller water at their mouths obstruction bars. ***Coast-lines.*** The best harbours are to be found on the *rias* or fjord-like indentations in the W. and N. of Galicia, where high tides keep the inlets well scoured; here occur the fine natural harbours of Pontevedra and Vigo, Corunna and Ferrol. Less varied in outline but more varied in character are the Spanish coasts on the south and east. The seaboard is generally flat from the frontier of Portugal to the Straits of Gibraltar. Between the mouth of the Rio Tinto and that of the Guadalquivir the shore is lined by a series of sand-dunes, known as the Arenas Gordas. Next follows a marshy tract at the mouth of the Guadalquivir known as Las Marismas, after which the coast-line becomes more varied, and includes the fine Bay of Cadiz. From the Straits of Gibraltar a bold and rocky coast continues almost to Cape Palos, a little beyond the fine natural harbour of Cartagena. North of Cape Palos a line of flat coast, beginning with the narrow strip which cuts off the lagoon called the Mar Menor from the Mediterranean, bounds half of the province of Alicante, but in its northern half this province, becoming mountainous, runs out to the lofty headland of Cape de la Nâo. The whole coast of the Bay of Valencia is low and ill provided with harbours; and along the east of Catalonia stretches of steep and rocky coast alternate with others of an opposite character.

Surface. The surface of Spain is remarkable at once for its striking contrasts and its vast expanses of dreary uniformity. There are mountains rising with alpine grandeur above the snow-line, but often sheltering rich and magnificent valleys at their base. Naked walls of white limestone tower above dark woods of cork-oak and olive. In other parts, as in the Basque country, in Galicia, in the Serrania de Cuenca (between the headwaters of the Tagus and those of the Júcar), in the Sierra de Albarracin (between the headwaters of the Tagus and those of the Guadalaviar), there are extensive tracts of undulating forest-clad hill country, and almost contiguous to these there are apparently boundless plains, or tracts of level table-land, some almost uninhabitable, and some streaked with irrigation canals and richly cultivated—like the Requena of Valencia. While, again, continuous mountain ranges and broad plains and table-lands give the prevailing character to the scenery, there are, on the one hand, lofty isolated peaks, such as Monseny, Montserrat (*q.v.*) and Mont Sant in Catalonia, the Peña Golosa in Valencia, Moncayo on the borders of Aragon and Old Castile, and, on the other hand, small secluded valleys, such as those of Vich and Olot among the Catalonian Pyrenees.

Central Table-land. The greater part of the interior of Spain is composed of a table-land bounded by the Cantabrian Mountains in the north and the Sierra Morena in the south, and divided into two by a series of mountain ranges stretching on the whole from east to west. The northern half of the table-land, made up of the provinces of Leon and Old Castile, has an average elevation estimated at about 2700 ft., while the southern half, made up of Estremadura and New Castile, is slightly lower—about 2600 ft. On all sides the table-land as a whole is remarkably isolated, and hence the passes on its boundary and the river valleys that lead down from it to the surrounding plains are geographical features of peculiar importance. The isolation on the side of Portugal has already been mentioned. On the north-west the valley of the Sil and a series of valleys farther south, along both of which military roads have been carried from an early period, open up communication between Leon and the hill country of Galicia, which explains why this province was united to Leon even before the conquest of Portugal from the Moors. The passes across the Cantabrian Mountains in the north are tolerably numerous, and several of them are crossed by railways. The two most remarkable are the Pass of Pájares, across which winds the railway from Leon to Oviedo and the seaport of Gijón, and that of Reinosa leading down to the deep valley of the Besaya, and crossed by the railway from Valladolid to Santander. In its eastern section the chain is crossed by the railways from Burgos to Bilbao and San Sebastian; the last-named line winds through the wild and romantic gorge of Pancorbo (in the north-east of the province of Burgos) before it traverses the Cantabrian chain at Idiazabal.

On the north-east and east, where the edge of the table-land sweeps round in a wide curve, the surface sinks in broad terraces to the valley of the Ebro and the Bay of Valencia, and is crowned by more or less isolated mountains, some of which have been already mentioned. On the north-east, by far the most important communication with the Ebro valley is formed by the valley of the Jalon, which has thus always formed a military route of the highest consequence, and is now traversed by the railway from Madrid to Saragossa. Farther south the mountains clustered on the east of the table-land (Sierra de Albarracin, Serrania de Cuenca) long rendered direct communication between Valencia and Madrid extremely difficult, and the principal communications with the east and south-east are effected where the southern table-land of La Mancha (*q.v.*) merges in the hill country which connects the interior of Spain with the Sierra Nevada.

In the south the descent from the table-land to the valley of the Guadalquivir is again comparatively gradual, but even here in the eastern half of the Sierra Morena the passes are few, the most important being the Puerto de Despeñaperros, where the Rio Magaña, a sub-tributary of the Guadalimar, has cut for itself a deep gorge through which the railway aseends from Andalusia to Madrid. Between Andalusia and Estremadura farther west the communieation is freer, the Sierra Morena being broken up into series of small chains.

Mountains. Of the mountains belonging to the table-land the most continuous are those of the Cantabrian chain, which stretches for the most part from east to west, parallel to the Bay of Biscay, but ultimately bends round towards the south between Leon and Galicia (see CANTABRIAN MOUNTAINS). A peculiar feature of this chain, and of the neighbouring parts of the table-land, is the number of the *parameras* or isolated plateaus, surrounded by steep rocky mountains, or even by walls of sheer cliff. The bleak districts of Sigüenza and Soria, round the headwaters of the Douro, separate the mountains of the so-called Iberian system on the north-east of the table-land from the eastern portion of the central mountain chains of the peninsula. Of these chains, to which Spanish geographers give the name Carpetano-Vetonica, the most easterly is the Sierra de Guadarrama, the general trend of which is from south-west to north-east. It is the Montes Carpetani of the ancients, and a portion of it (due north of Madrid) still bears the name of Carpetanos. Composed almost entirely of granite, it has an aspect when seen from a distance highly characteristic of the mountains of the Iberian Peninsula in general, presenting the appearance of a saw-like ridge (*sierra*) broken up into numerous sections. Its mean height is about 5250 ft., and near its centre it has three summits, the highest (named the Pico de Peñalara) rising to a height of 6910 ft. The chief passes across the Sierra are those of Somosierra (4692 ft.) in the north-east, Navacerrada (5837 ft.), near Peñalara, and Guadarrama (5010 ft.), a few miles farther south and west; these are crossed by earriage roads. The railway from Madrid to Segovia passes through a tunnel close to the Guadarrama Pass; and the railway from Madrid to Ávila traverses the south-western portion of the range through a remarkable series of tunnels and cuttings.

A region with a highly irregular surface, filled with hills and parameras, separates the Sierra de Guadarrama from the Sierra de Gredos farther west. This is the loftiest and grandest sierra in the whole series. Its culminating point, the Plaza de Almanzor, attains the height of 8730 ft., not far short of that of the highest Cantabrian summits. Its general trend is east and west; towards the south it sinks precipitously, and on the north it descends with a somewhat more gentle slope towards the longitudinal valleys of the Tormes and Alberche which separate it from another rugged mountain range, forming the southern boundary of the paramera of Ávila. On the west another rough and hilly tract, similar to that which divides it from the Sierra de Guadarrama in the east, separates it from the Sierra de Gata, the westernmost and the lowest of the Spanish sierras belonging to the series. These hilly intervals between the more continuous sierras greatly facilitate the communication between the northern and southern halves of the Spanish table-land. The Sierra de Gredos has a road aeross it connecting Ávila with Talavera de la Reina by the Puerto del Pico; but for the most part there are only bridle-paths across the Gredos and Gata ranges, and no railway crosses either of them, although the line from Plasencia to Salamanca skirts the Sierra de Gredos on the west. The Serra da Estrella, in Portugal, is usually regarded as a fourth section in the Carpetano-Vetonica chain.

On the southern half of the table-land a shorter series of sierras, consisting of the Montes de Toledo in the east (highest elevation Tejadillas, 4567 ft.) and the sierras of San Pedro, Montanchez and Guadalupe in the west (highest elevation Cabeza del Moro, 5100 ft.), separates the basins of the Tagus and Guadiana. The southern system of mountains bounding the Iberian table-land—the Sierra Morena (*q.v.*)—is even less of a continuous chain than the two systems last described. As already intimated, its least continuous portion is in the west. In the east and middle portion it is composed of a countless number of irregularly-disposed undulating mountains all nearly equal in height.

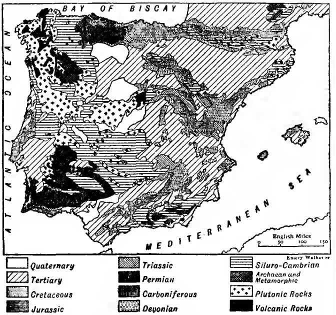
Even more important than the mountains bounding or crossing the table-land are those which are connected with it only at their extremities; viz. the Pyrenees (*q.v.*) in the north-east, the Sierra Nevada (*q.v.*) and the coast ranges in the south. The transverse valleys of the Sierra Nevada open southwards into the mountainous longitudinal valleys of the Alpujarras (*q.v.*), into which open also on the other side the transverse valleys from the most easterly of the coast sierras, the Sierra Contraviesa and the Sierra de Almijara. These ranges are continued farther west by the Sierra de Alhama and Sierra de Abdalajiz. Immediately to the west of the last-named sierra is the gorge of the Guadalhorce, which affords a passage for the railway from Malaga to Cordova; and beyond that gorge, to the west and south-west, the Serrania de Ronda, a mountain group difficult of access, stretches out its sierras in all directions. To Spanish geographers the coast ranges just mentioned are known collectively as the Sierra Penibetica. Although not comparable in altitude with the Pyrenees (highest summit Aneto, 11,168 ft.) or the Sierra Nevada (highest summit Mulhacen, 11,421 ft.), the coast ranges frequently attain an elevation of over 5000 ft., and in some cases of over 6000 ft. North-east of the Sierra Nevada two small ranges, Alcaraz and La Sagra, rise with remarkable abruptness from the plateau of Murcia, where it merges in that of the interior.

Lowland Valleys. The only two important lowland valleys of Spain are those of the Ebro and the Guadalquivir. The Ebro valley oecupies the angle in the north-east between the Pyrenees and the central table-land, and is divided by ranges of heights proceeding on the one side from the Pyrenees, on the other from the base of the Moncayo, into two portions. The uppermost of these, a plateau of between 1000 and 1300 ft. above sea-level, is only about one-fourth of the size of the remaining portion, which is chiefly lowland, but is cut off from the coast by a highland tract connecting the interior table-land with spurs from the Pyrenees. The Guadalquivir basin is likewise divided by the configuration of the ground into a small upper portion of considerable elevation and a much larger lower portion mainly lowland, the latter composed from Seville downwards of a perfectly level and to a large extent unhealthy alluvium (*Las Marismas*). The division between these two seetions is indicated by the change in the course of the main stream from a due westerly to a more south-westerly direction.

Rivers and Lakes. The main water-parting of the Peninsula is everywhere near the edge of the table-land on the north, east and south, and hence describes a semicircle with the convexity to the east. There are five great rivers in the Peninsula, the Tagus (Spanish *Tajo*, Portuguese *Tejo*), Douro (Spanish *Duero*), Ebro, Guadiana and Guadalquivir, all of which rise in Spain. The Ebro alone flows into the Mediterranean, and the Ebro and Guadalquivir alone belong wholly to Spain; the lower courses of the Tagus and Douro are bounded by Portuguese territory; and the lower Guadiana flows partly through Portugal, partly along the frontier. The Tagus rises in the Montes Universales on the borders of Teruel, and flows in a westerly direction until it enters the Atlantie below Lisbon, after a total course of 565 m. The Douro (485 m.) and the Ebro (466 m.) flow respectively south-west to the Atlantic at Oporto, and south-east to the Mediterranean at Cape Tortosa, from their sources in the great northern watershed. The Guadiana (510 m.) passes west and south through La Mancha and Andalusia to fall into Cadiz Bay at Ayamonte; and the Guadalquivir (360 m.) takes a similar direction from its headwaters in Jaen to Sanlucar de Barrameda, where it also enters Cadiz Bay farther south. These five rivers, as also the smaller Júcar and Segura, which enter the Mediterranean, are fully described in separate articles. With the exception of the Guadalquivir, none of them is of great service for inland navigation, so far as they lie within the Spanish frontier. On the other hand, those of the east and south are of great value for irrigation, and the Júcar and Segura are employed in floating timber from the Serrania de Cuenca. The only considerable lakes in Spain are three coast lagoons—the Albufera (*q.v.*) de Valencia, the Mar Menor in Murcia and the Laguna de la Janda in Cadiz behind Cape Trafalgar (see MURCIA and CADIZ). Small alpine and other lakes are numerous, and small salt lakes are to be found in every steppe region.

Geology.—Geologically the Spanish Peninsula consists of a great massif of ancient rock, bordered upon the north, east and south by zones of folding in which the Mesozoic and early Tertiary beds are involved. The massif is composed of Archean, Palaeozoic and eruptive rocks, partly concealed by a covering of Tertiary strata, but characterized by the absence, excepting on its margins, of any marine deposits of Mesozoic age. It stretches from Galicia and Asturias on the north to the valley of the Guadalquivir on the south, and includes the mountains of Castile, the Sierra de Toledo and the Sierra Morena. The rocks which form it are often strongly folded, but the folding is of ancient date and strikes obliquely across the massif and has had no influence in determining its outline. The massif is in faet merely a fragment of the great Hercynian mountain system which was formed across Europe at the close of the Carboniferous period. During the Mesozoie era this mountain ehain was shattered and large portions of it sank beneath the sea and were covered by Mesozoic and Tertiary strata. But other fragments still rose above the waves, and of these the great massif of Portugal and western Spain was one. Around it the deposits of the Jurassie and Cretaceous seas were laid down; and during the Tertiary era they were crushed, together with the earlier Tertiary beds, against the ancient rocks, and thus formed the folded zones of the Cordillera Betica on the south, the hills of southern Aragon on the east and the Pyrenees on the north. The intervening plains and plateaus are now for the most part covered by Tertiary deposits, whieh also spread over much of the ancient massif.

Archean rocks are exposed in the north of the Peninsula, particularly along the great Pyrenean axis, in Galicia, Estremadura, the Sierra Morena, the Sierra Nevada and Serrania de Ronda. They consist of granites, gneisses and mica-schists, with talc-schists, amphibolites and crystalline limestones. The oldest Palaeozoic strata are referred, from their included fossils, to the Cambrian, Ordovician and Silurian systems. They range through a vast region of Andalusia, Estremadura, Castile, Salamanca, Leon and Asturias, and along the flanks of the Pyrenean and Cantabrian ehain. They consist of slates, greywackes, quartzites and diabases. Grits, quartzites, shales and limestones referable to the Devonian system are found in a few scattered areas, the largest and most fossiliferous of these occurring in Asturias. The Lower Carboniferous rocks of Spain consist partly of limestones, and partly of shales, sandstones and conglomerates like the culm of Devonshire. It is in the culm of the province of Huelva that the celebrated copper mines of Rio Tinto are worked. The Upper Carboniferous is formed to a large extent of sandstones and shales, with seams of coal; but beds of massive limestones are often intercalated, and some of these contain *Fusulina* and other fossils like those of the Russian Fusulina limestone. The system is most extensively developed in the north, covering a considerable space in Asturias, whence it stretches more or less continuously through the provinces of Leon, Palencia and Santander. Another tract, about 500 sq. kilometres in extent, runs



from the province of Cordova into that of Badajoz. It is in this area that the important coal deposits of Penarroja are found. There are other smaller areas containing little or no coal, but showing by the included plant-remains that the strata undoubtedly belong to the Carboniferous system.

The Permian is probably represented by some of the red sandstones, conglomerates and shales in the Pyrenees, in the Serrania de Cuenca, and in Andalusia. The Triassic system is well developed in the north of the peninsula along the Cantabrian chain and eastwards to the Mediterranean. It is composed of red and variegated sandstones, dolomites and marls, traversed in some places by ophitic rocks, and containing deposits of gypsum, aragonite and rock-salt. It thus resembles the Trias of England and Germany. In the south-east, however, and at the mouth of the Ebro, limestones are found containing a fauna similar to that of the alpine Trias. These strata are overlain by members of the Jurassic series, which are especially conspicuous in the eastern part of the peninsula between Castile and Aragon, along the Mediterranean border, in Andalusia, and likewise along the flanks of the Pyrenees. The Jurassic of Andalusia belongs to the Mediterranean facies of the system; the Jurassic of the rest of Spain is more nearly allied to that of north-western Europe. The Cretaceous system is distributed in four great districts: the largest of these extends through the kingdoms of Murcia and Valencia; a second stretches between the two Castiles; a third is found in the Basque Provinces and in Asturias; and a fourth spreads out along the southern slopes of the Pyrenees from Navarre to the Mediterranean. The lower members of the Cretaceous series include an important fresh-water formation (sandstones and clays), which extends from the Cantabrian coast through the provinces of Santander, Burgos, Soria and Logroño, and is supposed to represent the English Wealden series. The higher members comprise massive hippurite limestones, and in the Pyrenean district representatives of the upper subdivisions of the system, including the Danian.

Deposits of Tertiary age cover rather more than a third of Spain. They are divisible into two great series, according to their mode of origin in the sea or in fresh-water. The marine Tertiary accumulations commence with those that are referable to the Eocene series, consisting of nummulitic limestones, marls and siliceous sandstones. These strata are developed in the basin of the Ebro, and in a belt which extends from Valencia through Murcia and Andalusia to Cadiz. Marine Miocene deposits occupy some small tracts, especially on the coast of Valencia. But most of the sandy Tertiary rocks of that district are Pliocene. The Tertiary strata of Andalusia are specially noteworthy for containing the native silver of Herrerias, which is found in a Pliocene bed in the form of flukes, needles and crystals. But the most extensive and interesting Tertiary accumulations are those of the great lakes which in Oligocene and Miocene time spread over so large an expanse of the table-land. These sheets of fresh-water covered the centre of the country, including the basins of the Ebro, Júcar, Guadalaviar, Guadalquivir and Tagus. They have left behind them thick deposits of clays, marls, gypsum and limestone, in which numerous remains of the land-animals of the time have been preserved.

Quaternary deposits spread over about a tenth of the area of the country. The largest tract of them is to be seen to the south of the Cantabrian chain; but another, of hardly inferior extent, flanks the Sierra de Guadarrama, and spreads out over the great plain from Madrid to Cáceres. Some of these alluvial accumulations indicate a former greater extension of the snowfields that are now so restricted in the Spanish sierras. Remains of the reindeer are found in caves in the Pyrenees.

Eruptive rocks of many different ages occur in different parts of Spain. The most important tract covered by them is that which stretches from Cape Ortegal to Coria in Estremadura and spreads over a large area of Portugal. They likewise appear in Castile, forming the sierras of Gredos and Guadarrama; farther south they rise in the mountains of Toledo, in the Sierra Morena, and across the provinces of Cordova, Seville, Huelva and Badajoz as far as Evora in Portugal. Among the minor areas occupied by them may be especially mentioned those which occur in the Trinssic districts. Of rocks included in the eruptive series the most abundant is granite. There occur also quartz-porphyry (Sierra Morena, Pyrenees, &c.), diorite, porphyrite, diabase (well developed in the north of Andalusia, where it plays a great part in the structure of the Sierra Morena), ophite (Pyrenees, Cadiz), serpentine (forming an enormous mass in the Serrania de Ronda), trachyte, liparite, andesite, basalt. The last four rocks occur as a volcanic series distributed in three chief districts—that of Cape Gata, including the south-east of Andalusia and the south of Murcia, that of Catalonia, and that of La Mancha.

Climate.—In accordance with its southerly position and the variety in its superficial configuration, Spain presents within its borders examples of every kind of climate to be found on the northern hemisphere, with the sole exception of that of the torrid zone. As regards temperature, the heart of the table-land is characterized by extremes as great as are to be met in almost any part of central Europe. The northern and north-western maritime provinces, on the other hand, have a climate as equable, and as moist, as that of the west of England or Scotland.

Four zones of climate are distinguished. The first zone is that of the table-land, with the greater part of the Ebro basin. This is the zone of the greatest extremes of temperature. Even in summer the nights are often decidedly cold, and on the high parameras it is not a rare thing to see hoar-frost in the morning. In spring cold, wetting mists occasionally envelop the land for entire days, while in summer the sky is often perfectly clear for weeks together. At all seasons of the year sudden changes of temperature, to the extent of from 30° to 50° F., are not infrequent. The air is extremely dry, which is all the more keenly felt from the fact that it is almost constantly in motion. At Madrid (2150 ft. above sea-level) it freezes so hard in December and January that skating is carried on on the sheet of water in the Buen Retiro; and, as winter throughout Spain, except in the maritime provinces of the north and north-west, is the season of greatest atmospheric precipitation, snowfalls are frequent, though the snow seldom lies long except at high elevations. The summers, on the other hand, are not only extremely warm but almost rainless, the sea-winds being deprived of their moisture on the edge of the plateau. In July and August the plains of New Castile and Estremadura are sunburnt wastes; the roads are several inches deep with dust; the leaves of the few trees are withered and discoloured; the atmosphere is filled with a fine dust, producing a haze known as *calina*, which converts the blue of the sky into a dull grey. In the greater part of the Ebro basin the heat of summer is even more intense. The treeless mostly steppe-like valley with a bright-coloured soil acts like a concave mirror in reflecting the sun's rays and, moreover, the mountains and highlands by which the valley is enclosed prevent to a large extent the access of winds.

The second zone is that of the Mediterranean provinces, exclusive of those of the extreme south. In this zone the extremes of temperature are less, though the summers here also are warm, and the winters decidedly cool, especially in the north-east.

The southern zone, to which the name of African has been given, embraces the whole of Andalusia as far as the Sierra Morena, the southern half of Murcia and the province of Alicante. In this zone there prevails a genuine sub-tropical climate, with extremely warm and almost rainless summers and mild winters, the temperature hardly ever sinking below freezing-point. The hottest part of the region is not the most southerly district but the bright-coloured steppes of the coast of Granada, and the plains and hill terraces of the south-east coast from Almeria to Alicante. Snow and frost are here hardly known. It is said that at Malaga snow falls only about once in twenty-five years. The winter, in fact, is the season of the brightest vegetation: after the long drought of summer the surface gets covered once more in late autumn with a fresh green varied with bright-coloured flowers, and so it remains the whole winter through. On the other hand, the eastern part of this zone is the part of Spain which is liable to be visited from time to time by the scorching *leveche*, the name given in Spain to the sirocco, as well as by the *solano*, a moist and less noxious east wind.

The fourth zone, that of the north and north-west maritime provinces, presents a marked contrast to all the others. The temperature is mild and equable; the rains are abundant all the year round, but fall chiefly in autumn, as in the west of Europe generally. Roses bloom in the gardens at Christmas as plentifully as in summer. The chief drawback of the climate is an excess of rain in some parts, especially in the west. Santiago de Compostela, for example, has one of the highest rainfalls on the mainland of Europe (see table below).

The figures given in the following table,[1] although based only on data of short periods (from $3\frac{1}{2}$ to 20 years), will help to illustrate the preceding general remarks. Greenwich is added for the sake of comparison.

Station.		Height in feet.	Mean Temperature, F.			Rain-fall in inches.
			Jan.	July.	Year.

Flora.—The vegetation of Spain exhibits a variety in keeping with the differences of climate just described. The number of endemic species is exceptionally large, the number of monotypic genera in the Peninsula greater than in any other part of the Mediterranean domain. The endemic species are naturally most numerous in the mountains, and above all in the loftiest ranges, the Pyrenees and the Sierra Nevada; but it is a peculiarity of the Spanish table-land, as compared with the plains and table-lands of central Europe, that it also possesses a considerable number of endemic plants and plants of extremely restricted range. This fact, however, is also in harmony with the physical conditions above described, being explained by the local varieties, not only of climate, but also of soil. Altogether no other country in Europe of equal extent has so great a wealth of species as Spain. According to the *Prodromus florae hispanicae* of Willkomm and Lange (completed in 1880), the number of species of vascular plants then ascertained to exist in the country was 5096.

Spain may be divided botanically into four provinces, corresponding to the four climatic zones.

In the table-land province (including the greater part of the Ebro valley) the flora is composed chiefly of species characteristic of the Mediterranean region, and largely of species confined to the Peninsula. A peculiar character is imparted to the vegetation of this province by the growth over large tracts of evergreen shrubs and large herbaceous plants belonging to the Cistineae and Labiatae. Areas covered by the Cistineae are known to the Spaniards as *jarales*, and are particularly extensive in the Mancha Alta and on the slopes of the Sierra Morena, where the ladanum bush (*Cistus ladaniferus*) is specially abundant; those covered by the Labiatae are known as *tomillares* (from *tomillo*, thyme), and occur chiefly in the south, south-west and east of the table-land of New Castile. In the central parts of the same table-land huge thistles (such as the *Onopordum nervosum*), centaureas, artemisias and other Compositae are scattered in great profusion. From the level parts of these table-lands trees are almost entirely absent. On the lofty parameras of Soria and other parts of Old Castile the vegetation has an almost alpine character.

The southern or African province is distinguished chiefly by the abundance of plants which have their true home in North Africa (a fact explained by the geologically recent land connexion of Spain with that continent), but is also remarkable for the occurrence within it of numerous Eastern plants (natives of Syria and Asia Minor), and plants belonging to South Africa and the Canaries, as well as natives of tropical America which have become naturalized here (see *Agriculture*). In the maritime parts of Malaga and Granada the vegetation is of almost tropical richness and beauty, while in Murcia, Alicante and Almeria the aspect is truly African, fertile oases appearing in the midst of rocky deserts or barren steppes. A peculiar vegetation, consisting mainly of low shrubs with fleshy glaucous leaves (*Inula crithmoides*, &c.), covers the swamps of the Guadalquivir and the salt-marshes of the south-west coast. Everywhere on moist sandy ground are to be seen tall thickets of *Arundo donax*.

The Mediterranean province is that in which the vegetation agrees most closely with that of southern France and the lowlands of the Mediterranean region generally. On the lower slopes of the mountains and on all the parts left uncultivated the prevailing form of vegetation consists of a dense growth of shrubs with thick leathery leaves, such as are known to the French as *maquis*, to the Italians as *macchie*, and to the Spaniards as *monte bajo*,[2] shrubs which, however much they resemble each other in external appearance, belong botanically to a great variety of families.

The northern maritime province, in accordance with its climate, has a vegetation resembling that of central Europe. Here only are to be found rich grassy meadows covered with flowers such as are seen in English fields, and here only do forests of oak, beech and chestnut cover a large proportion of the area. The extraordinary abundance of ferns (as in western France) is likewise characteristic.

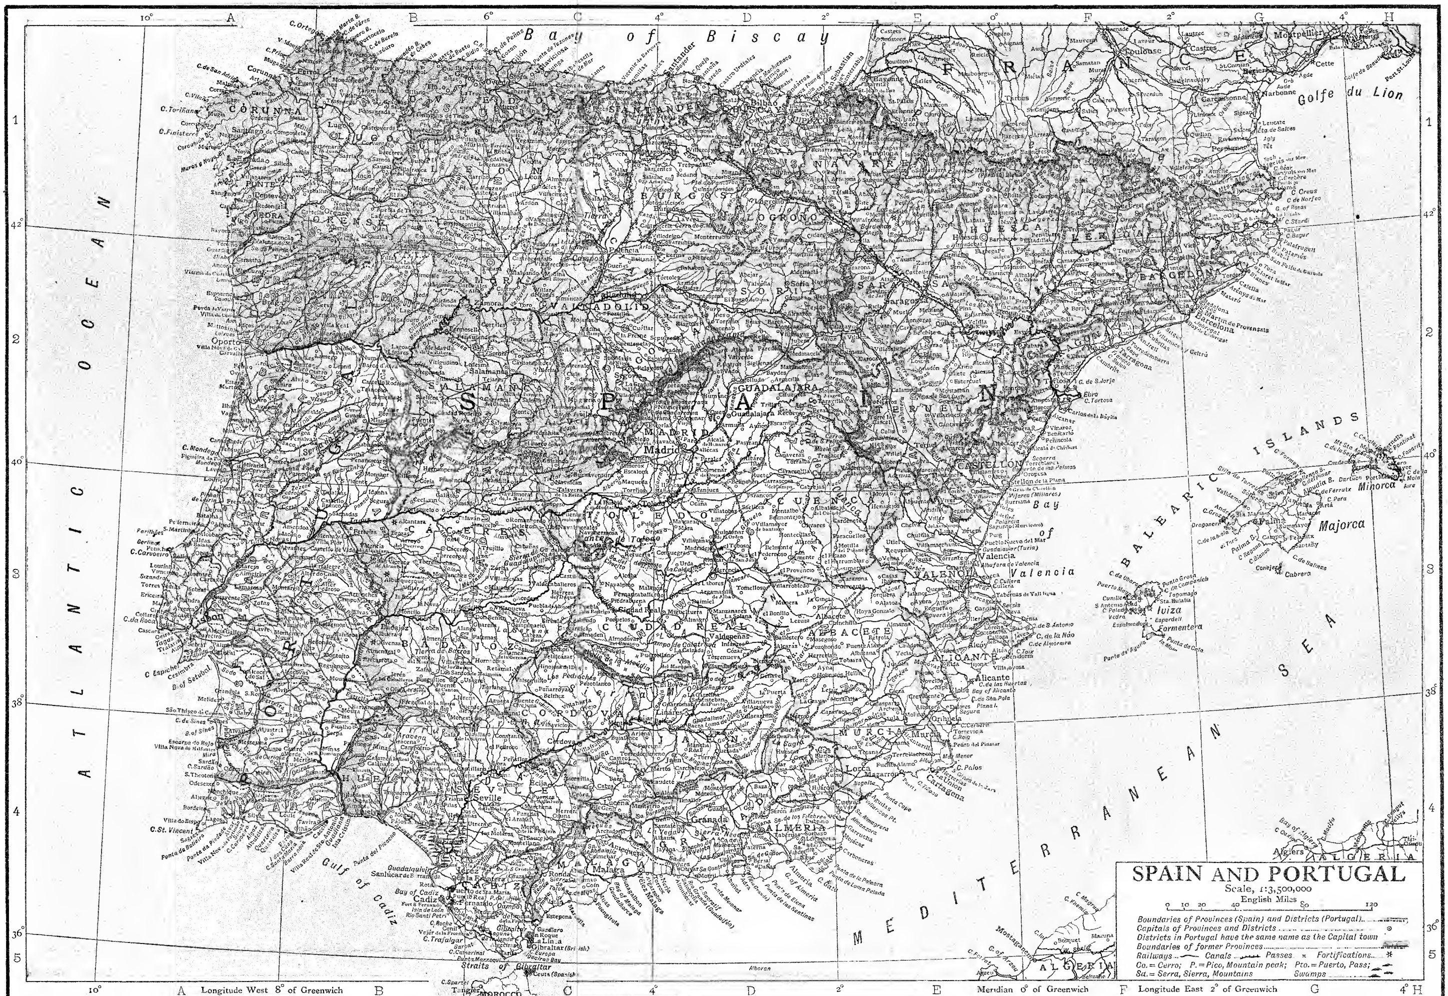
The forest area of Spain is relatively small. The whole extent of forests is estimated at little more than $7\frac{1}{2}$ million acres, or less than 6% of the area of the kingdom. Evergreen oaks, chestnuts and conifers are the prevailing trees. The cork oaks of the southern provinces and of Catalonia are of immense value, but the groves have suffered greatly from the reckless way in which the produce is collected. Among other characteristic trees are the Spanish pine (*Pinus hispanica*), the Corsican pine (*P. Laricio*), the Pinsapo fir (*Abies Pinsopo*), and the *Quercus Tozza*, the last belonging to the slopes of the Sierra Nevada. Besides the date-palm the dwarf-palm grows spontaneously in some parts of the south, but it nowhere makes up a large element of the vegetation.

The Spanish steppes deserve a special notice, since they are not confined to one of the four botanical provinces, but are found in all of them except the last. Six considerable steppe regions are counted: (1) that of Old Castile, situated to the south of Valladolid, and composed chiefly of hills of gypsum; (2) that of New Castile, in the south-east (including parts of La Mancha); (3) the Aragonese, occupying the upper part of the basin of the Ebro; (4) the littoral, stretching along the south-east coast from Alicante to the neighbourhood of Almeria; (5) the Granadine, in the east of Upper Andalusia (the former kingdom of Granada); and (6) the Baetic, in Lower Andalusia, on both sides of the valley of the Jenil or Genil. All of these were originally salt-steppes, and, where the soil is still highly impregnated with salt, have only a sparse covering of shrubs, mostly members of the Salsolaceae, with thick, greyish green, often downy leaves. A different aspect is presented by the grass steppes of Murcia, La Mancha, the plateaus of Guadix and Huescar in the province of Granada, &c., all of which are covered chiefly with the valuable esparto grass (*Macrochloa tenacissima*).

Fauna.—The Iberian Peninsula belongs to the Mediterranean sub-region of the Palaearctic region of the animal kingdom. The forms that betray African affinities are naturally to be found chiefly in the south. Among the mammals that fall under this head are the common genet (*Genetta vulgaris*), which extends, however, pretty far north, and is found also in the south of France, the fallow-deer, the porcupine (very rare), and a species of ichneumon (*Herpestes Widdringtonii*), which is confined to the Peninsula, and is the only European species of this African genus. The magot or Barbary ape (*Inuus ecaudatus*), the sole species of monkey still found wild in Europe, is also a native of Spain, but only survives on the rock of Gibraltar (*q.v.*). Of the mammals in which Spain shows more affinity to the fauna of central and northern Europe, some of the most characteristic are the Spanish lynx (*Lynx pardinus*), a species confined to the Peninsula, the Spanish hare (*Lepus madritensis*), and the species mentioned in the article PYRENEES. The birds of Spain are very numerous, partly because the Peninsula lies in the route of those birds of passage which cross from Africa to Europe or Europe to Africa by way of the Straits of Gibraltar. Many species belonging to central Europe winter in Spain, especially on the south-eastern coasts and in the valley of the Guadalquivir. Innumerable snipe are killed in the Guadalquivir valley and brought to the market of Seville. Among the birds of prey may be mentioned, besides the cinereous and bearded vultures, the Spanish vulture (*Gyps occidentalis*), the African or Egyptian vulture (*Neophron percnopterus*), which is found among all the mountains of the Peninsula, the Spanish imperial eagle (*Aquila Adalberti*), the short-toed eagle (*Circaetus gallicus*), the southern eagle-owl (*Bubo atheniensis*), and various kites and falcons. Among gallinaceous birds besides the red-legged partridge, which is met with everywhere on the steppes, there are found also the *Pterocles alchita* and *P. arenarius*; and among the birds of other orders are the southern shrike (*Lanius meridionalis*), the Spanish sparrow (*Passer cyaneus*), and the blue magpie (*Cyanopica cooki*). The last is highly remarkable on account of its distribution, it being confined to Spain while the species most closely allied to it (*Cyanopica cyanea*) belongs to the east of Asia. The flamingo is found native in the Balearic Islands and on the southern coasts, and a stray specimen is occasionally seen on the table-land of New Castile. Other birds peculiar to the south are two species of quails, the Andalusian hemipode (*Turnix sylvatica*), confined to the plains of Andalusia, the southern shearwater (*Puffinus cinereus*), and other water-birds. Amphibians and reptiles are particularly numerous in the southern provinces, and among these the most remarkable are the large southern or eyed lizard (*Lacerta*

[1] By conversion from Th. Fischer's *Klima der Mittelmeerländer*.

[2] As distinguished from *monte alto*, the collective name for forest trees.



Emery Walker sc.

ocellata), which sometimes attains 3 ft. in length and is very abundant; the *Platydactylus saccicularis*, the grey amphisbaena (*Blanus cinereus*), the European pond-tortoise (*Emys europaea*), and another species, *Emys Siegrizii*. Insect life is remarkably abundant and varied. More than 350 species of butterflies, many of them endemic, have been counted in the province of Madrid alone. Besides the ordinary European scorpion, which is general in southern Europe, there is another species, the sting of which is said to be still more severe, found chiefly in the basin of the Ebro. Trout abound in the mountain streams and lakes, barbel and many other species of *Cyprinidae* in the rivers of the plains. For the sea fauna, see under *Fisheries* below.

Territorial Divisions and Population.—For administrative purposes the kingdom of Spain has since 1833 been divided into forty-nine provinces, forty-seven of which belong to the mainland. Before 1833 the mainland was divided into thirteen provinces, also enumerated below, which took their names from the ancient kingdoms and principalities out of which the modern kingdom was built up. All the continental provinces, ancient and modern, as also the Balearic Islands, Canary Islands, Annobon, Ceuta, Corisco, the Chaffarinas, Fernando Po, the Muni River Settlements and Rio de Oro are described in separate articles.

It is probable that the population of Spain attained its height during the early Roman Empire, when it has been estimated, though of course on imperfect data, to have numbered forty or fifty millions. The best evidence of a dense population in those days is that afforded by the specific estimates of ancient writers for some of the larger cities. The population of Tarraco (Tarragona) was estimated at 2½ millions, and those of Nova Carthago (Cartagena), Italica (Sevilla la Vieja), and other cities at several hundreds of thousands. Emerita Augusta (Mérida) had a Roman garrison of 90,000 men, which also implies a large population.

The first Spanish census was made in 1594, but some of the provinces now included in the kingdom were not embraced in the enumeration, so that the total population assigned to Spain within its present limits for that date is obtained by adding the results of enumerations at different dates in the provinces then excluded. The total thus arrived at is 8,206,791. No other census took place till 1787, when the total was found to be 10,268,150; and this census was followed by another in 1797, when the population was returned as 10,541,221. Various estimates were made within the next sixty years, but the census of 1857 proved that some of these estimates must have been greatly below the truth. The total population then ascertained to exist in Spain was 15,464,340, an increase of not much less than 50% since the census of 1797. Between 1857 and 1877 the population increased to 16,631,869; and by 1897 it had risen to 18,132,475. The annual rate of increase during this period of forty years was less than ·45%, or lower than that of any other European state, except France in the later years of the 19th century. The census of 1900, however, showed that the annual rate of increase had risen, between 1897 and 1900, to ·89%, or nearly double its former amount. This fact may be explained partly by the growth of mining and certain other industries, partly, perhaps, by the recuperative power which the Spanish people has always exhibited after war—the most notable instance of which is the above-mentioned net increase of nearly 50% between 1797 and 1857, despite the Napoleonic invasion and other disastrous wars. A similar though much smaller acceleration in the annual rate of increase after the Carlist Wars of 1874–76 is largely attributable to the prosperity caused by railway development between 1877 and 1887. It would be unjustifiable to assume from the inadequate data available that the Spanish people retains the vitality which characterized it from 1797 to 1857. It is, however, clear from the census returns that at the beginning of the 20th century

Area and Population of the Former and Present Provinces.

Provinces.	Area in sq. m.	Pop., 1857.	Pop., 1887.	Pop., 1900.	Pop. per sq. m., 1900.

the nation was well able to make good the numerical losses involved by a serious war; that its numbers tend to increase steadily; and that the rate of increase has hitherto shown a marked acceleration in periods of commercial expansion.

The estimated area and population of the Spanish possessions in Africa, exclusive of Ceuta, are shown below:—

	Area in sq. m.	Pop.
Rio de Oro	70,000	130,000
Muni River Settlements	9,800	140,000
Fernando Po, Annobon, Corisco, &c.	800	22,000
Melilla, Ifni, &c.	40	15,000
Totals	80,640	307,000

Its extraordinary lack of population differentiates Spain from every other country possessed of equal natural advantages and an historic civilization. Spain occupies an unsurpassed geographical position; its resources are rich, varied and to some extent unexploited; its inhabitants include the Basques and Catalans, noted for their commercial enterprise, and the Galicians, noted for their industry. Nevertheless this country, which appears, more than 2000 years ago, to have supported a population nearly thrice as numerous as its present inhabitants and larger than that of the United Kingdom in 1901, is almost as thinly peopled as the most deserted province of Ireland (Connaught 94·5 inhabitants per sq. m.). The depopulation of Spain dates certainly from the Moorish conquest, possibly from the earlier Visigothic invasion. The Moors decimated the native population; when they in turn were expelled, the country lost not only a numerically large section of its inhabitants, but the section best able to develop its natural wealth. The wars of the 16th, 17th and 18th centuries, and the vast potentialities of fortune which drew men to the Spanish colonies in America, caused a further serious drain upon the population.

As regards the distribution of population between town and country, Spain contrasts in a marked manner with Italy, Spain having but few large towns and a relatively large country population.

Communications.—The communications in Spain were greatly improved during the 19th century. In 1808 there were little more than 500 m. of carriage roads; in 1908 the aggregate length of the state, provincial and municipal roads was about 40,000 m. But there are still many parts of the country where trade—and especially mining—is retarded by the want of good roads. In the mountainous districts, where there are only narrow paths, frequently rather steep, it is still not uncommon to meet long trains of pack-mules, which, with ox-carts for heavier goods, constitute the sole means of transport in such regions.

Railways have made great advance since the middle of the 19th century. The oldest line is that from Barcelona to Mataró, 17½ m., which was opened on the 28th of October 1848. From 1850 onwards the rate of construction increased apace, and during the last decade of the 19th century about 205 m. were opened to traffic every year. In January 1910, 9020 m. had been completed, and the whole kingdom was covered by a network of railways which linked together all the principal towns. The Spanish railway system at this time communicated with the French at Irun and Portbou, west and east respectively of the Pyrenees; and with the Portuguese at or near Tuy on the northern frontier of Portugal, and near La Fregeneda, Ciudad Rodrigo, Valencia de Alcántara and Badajoz on the E. All the Spanish railways belong to private companies, most of which have received state subventions, and they will fall in to the government mostly at the end of 99 years. In granting a concession for a new railway the practice is to give it to the company that offers to construct it with the lowest subvention. For strategical reasons the Spanish gauge was made different from that of France; and military considerations long postponed the construction of any railway across the Pyrenees. The roads which wind through the Pyrenees in northern Aragon, Navarre and Catalonia had long been the channels of an important traffic, although great inconvenience was caused by the snow which blocks the passes in winter. In 1882 the French and Spanish governments proposed to overcome this obstacle by constructing two railways: one from Huesca to Oloron, through the Canfranc Pass, and through an international tunnel which was to be built at Somport; the other from the Ariège railway system to the Spanish northern system in the province of Lérida. The first line was completed on the Spanish side as far as Jaca, the second was only surveyed; both were opposed by the ministries of war in the two countries concerned. The matter was taken up at the beginning of the 20th century by M. Delcassé, the French minister for foreign affairs, and on the 18th of August 1904 a convention was signed providing for the construction of (1) the Huesca-Oloron line, (2) a line from Ax les Thermes in the Ariège to Ripoll in Catalonia, (3) a line from St Girons in the Ariège to Sort, and thence to Lérida. The Spanish government agreed to finish the Lérida-Sort section by 1915, and the Noguera Pallaresa valley was chosen as the route from Sort to the frontier, where junction with the French railways would be effected through the Port de Salau. All three schemes were ratified in 1904 by the Cortes and the French Chambers. Seventy per cent. of the railways of Spain, and an even larger proportion of the tramways and narrow-gauge railways, especially in mining districts, have been constructed and worked with foreign capital. The postal and telegraphic services have been placed on the same footing as in other civilized countries. In 1907 the number of letters and post-cards carried in the inland service was 133,201,000, in the international service 44,219,000. The length of state telegraph lines increased from 6665 m. in 1883 to 20,575 m. in 1903. In 1907 there were 84 urban telephone systems and 71 inter-urban circuits.

Agriculture.—Agriculture is by far the most important Spanish industry. In general it is in a backward condition, and is now much less productive than in the time of the Romans and again under the Moors. The expulsion of the latter people in many places inflicted upon agriculture a blow from which it has not recovered to this day. Aragon and Estremadura, the two most thinly peopled of all the old provinces, and the eastern half of Andalusia (above Seville), have all suffered particularly in this manner, later occupiers never having been able to rival the Moors in overcoming the sterility of nature, as in Aragon, or in taking advantage of its fertility, as in Andalusia and the Tierra de Barros. In some districts the implements used are still of the rudest description. The plough is merely a pointed stick shod with iron, crossed by another stick which serves as a share, scratching the ground to the depth of a few inches. But the regular importation of agricultural implements betokens an improvement in this respect. In general there has been considerable improvement in the condition of agriculture since the introduction of railways, and in every province there is a royal commissioner entrusted with the duty of supervising and encouraging this branch of industry. Among other institutions for the promotion of agriculture the royal central school at Aranjuez, to which is attached a model farm, is of special importance. Of the soil of Spain 79·65% is classed as productive; 33·8% being devoted to agriculture and gardens, 20·8 to fruit, 19·7 to grass, 3·7 to vineyards and 1·6 to olives. The land is subdivided among a very large number of proprietors; over 3,400,000 farms or estates were assessed for taxation in 1905.

The provinces in which agriculture is most advanced are those of Valencia and Catalonia, in both of which the river valleys are thickly seamed with irrigation canals and the hill-slopes carefully terraced for cultivation. In neither province is the soil naturally fertile, and nothing but the untiring industry of the inhabitants, favoured by the rivers which traverse the province from the table-land of New Castile and the numerous small streams (*nacimientos*) that issue from the base of the limestone mountains and by the numerous torrents from the Pyrenees, has converted them into two of the most productive regions in Spain. In the Basque Provinces and in Galicia the cultivable area is quite as fully utilized, but in these the difficulties are not so great. The least productive tracts, apart from Aragon and Estremadura, are situated in the south and east of New Castile, in Murcia, and in Lower Andalusia—the marshes or *marismas* of the lower Guadalquivir and the *arenas gordas* between that river and the Rio Tinto. By far the greater part of the table-land, however, is anything but fertile, the principal exceptions being the Tierra de Campos, said to be the chief corn-growing district in Spain, occupying the greater part of Palencia in the north-west of Old Castile, and the Tierra de Barros, in the portion of Badajoz lying to the south of the Guadiana in Estremadura.

Except in Leon and the provinces bordering on the Bay of Biscay and the Atlantic, irrigation is almost everywhere necessary for cultivation, at least in the case of certain crops. Almost all kinds of vegetables and garden-fruits, oranges, rice, hemp and other products are generally grown solely or mainly on irrigated land, whereas most kinds of grain, vines and olives are cultivated chiefly on dry soil. The water used for irrigation is sometimes derived from springs and rivers in mountain valleys, whence it is conveyed by long canals (*acequias*) along the mountain sides and sometimes by lofty aqueducts to the fields on which it is to be used. Sometimes the water of entire rivers or vast artificial reservoirs (*pántanos*) is used in feeding a dense network of canals distributed over plains many square miles in extent. Such plains in Valencia and Murcia are known by the Spanish name of *huertas* (gardens), in Andalusia by the Arabic name of *vegas*, which has the same meaning. Many of the old irrigation works—such as those of the plain of Tarragona—date from the time of the Romans, and many others from the Moorish period, while new ones are still being laid out at the present day. Where no running water is available for irrigation, water is often obtained from wells by means of waterwheels (*norias*) of simple construction. In most cases such wheels merely have earthenware pitchers attached to their circumference by means of wisps of esparto, and are turned by a horse harnessed to a long arm fitted to a revolving shaft. In recent years many artesian wells have been sunk for irrigation. In all, about 9% of the entire surface of Spain is artificially watered, but in 1900 the government adopted plans for the construction of new canals and reservoirs on a vast scale. The system was designed to bring a greatly increased area of arid or semi-arid land under irrigation. The irrigated portions of the Ebro and Tagus valleys yield twelve times as large a crop per acre as the unirrigated.

Cereals constitute the principal object of cultivation, and among these wheat ranks first, the next in importance being barley, the chief fodder of horses and mules. Both of these grains are eultivated in all parts, but chiefly on the more level districts of the two Castiles and Leon, and on the plains of the Guadalquivir basin. Oats and rye are cultivated only in the higher parts of the mountains, the former as a substitute for barley in feeding horses and mules, the latter as a breadstuff. Maize also is cultivated in all the provinces; nevertheless, its cultivation is limited, since, being a summer crop, it requires irrigation except in the Atlantic provinces, and other products generally yield a more profitable return where irrigation is pursued. Rice is cultivated on a large scale only in the swampy lowlands of Valencia. Among cereals of less importance are buckwheat (in the mountainous regions of the north), millets, including both the common millet (*Panicum miliaceum*) and the so-called Indian millet (*Sorghum vulgare*, the *joári* of India, the *durrah* of Africa), and even (in La Mancha) guinea-corn (*Penicillaria spicata*).

Grain.

Among the natural products of the soil of Spain, in regard to quantity, wines come next to cereals, but the only wines which have a world-wide reputation are those of the south, those of Alicante, of Malaga, and more particularly those which take the name of "sherry," from the town of Jerez, in the neighbourhood of which they are grown (see WINE). From 1880 to 1890 when the French vineyards suffered so much from various plagues. and when Spain gave a great impetus to her foreign trade by numerous treaties of commerce, none of her products showed such an increase in exports as her wines. The vine-growing districts had formerly been mostly in the provinces of Cadiz, Malaga, Barcelona, Aragon and Navarre. Then the vineyards spread all along the Ebro valley and in the Mediterranean seaboard provinces, as well as in New and Old Castile and Estremadura to such an extent that wine is now produced in all the 49 provinces of the kingdom. The average result of the vintage was estimated between 440 and 500 million gallons in 1880 to 1884, and it rose to more than double that amount towards 1890, and amounted in 1898 to 880 million gallons. In that year the total area under the vine was 3,546,375 acres, in 1908 it was 3,136,470 acres. In the hey-day of the cultivation of the vine Spain sent the bulk of her wine exports to France. The imposition of high duties in France on foreign wines in 1891 dealt a severe blow to the export trade in common Spanish wines. The export of wines of the south—Jerez, Malaga and other full-bodied wines styled *generoso*—did not suffer so much, and England and France continued to take much the same quantities of such wines. There is also a large export of grapes and raisins, especially from Malaga, Valencia, Almería and Alicante. The Spanish vines have suffered, like those of France, from mildew and phylloxera. The latter has done most damage in the provinces of Malaga and Alicante, in Catalonia. and in some parts of the Ebro valley in Navarre and Aragon. The vines whose fruit is intended for table use as grapes or raisins are trained on espaliers or on trees, especially the nettle-tree (*Celtis australis*).

Wines.

Among fruit-trees the first place belongs to the olive. Its range in Spain embraces the whole of the southern half of the table-land, the greater part of the Ebro valley, and a small strip on the west coast of Galicia. Along the base of the Sierra Morena from Andújar to the vicinity of Cordova there run regular forests of olives, embracing hundreds of square miles. Cordova is the headquarters of the oil industry, Seville of the cultivation of olives for table use. In 1908 the yield of oil amounted to 36,337,893 gallons. Oranges and lemons, excluded from the plateau by the severity of the winter cold, are grown in great quantities on the plains of Andalusia and all round the Mediterranean coast; the peel of the bigarade or bitter orange is exported to Holland for the manufacture of curaçao; and figs, almonds, pomegranates, carobs and other southern fruits are also grown abundantly in all the warmer parts, the first two even in central Spain and the more sheltered parts of the northern maritime provinces. In these last, however, the prevailing fruit-trees are those of central Europe, and above all the apple, which is very extensively cultivated in Asturias, the Basque Provinces and Navarre. In these provinces large quantities of cider are brewed. The date-palm is very general in the south-eastern half of the kingdom, but is cultivated for its fruit only in the province of Alicante, in which is the celebrated date-grove of Elche (*q.v.*). In the southern provinces flourish also various sub-tropical exotics, such as the banana, the West Indian cherimoya, and the prickly pear or Indian fig (*Opuntia vulgaris*), the last frequently grown as a hedge-plant, as in other Mediterranean countries, and extending even to the southern part of the table-land. It is specially abundant on the Balearic Islands. The agave or American aloe is cultivated in a similar manner throughout Andalusia.

Fruit.

Cotton is now cultivated only here and there in the south; but sugar-cane is, with sugar-beet, becoming more and more of a staple in the provinces of Granada, Malaga and Almería. Its cultivation was introduced by the Arabs in the 12th century or later, and was of great importance in the kingdom of Granada at the time of the expulsion of the Moors (1489), but has since undergone great vicissitudes, first in consequence of the introduction of the cane into America, and afterwards because of the great development of beet-sugar in central Europe. The industry received a powerful stimulus from the loss of the Spanish colonies in 1898, which freed the Spanish growers from the rivalry of their most suceessful competitors in the home market. In 1901 the official statistics showed 22 cane-sugar factories and 47 beet-sugar factories with an annual output of about 100,000 tons.

Sugar.

In the production of pod-fruits and kitchen vegetables Spain is ahead of many other countries. The ehick-pea forms part of the daily food of all classes of the inhabitants; and among other pod-fruits largely cultivated are various kinds of beans and peas, lentils (*Ervum lens*), Spanish lentils (*Lathyrus sativus*) and other species of *Lathyrus*, lupines, &c. The principal fodder-crops are lucerne (*Medicago sativa*) and esparcette (a variety of sainfoin). Clover, particularly crimson clover (*Trifolium incarnatum*), is grown in the northern provinces. Among vegetables garlic and onions take the chief place, and form an indispensable part of the diet of all Spaniards; besides these, tomatoes and Spanish pepper are the principal garden crops. Among the vegetable products not yet mentioned the most important are the mulberry, grown in almost all provinces, but principally in those bordering on the Mediterranean, and above all in Valencia, the chief seat of the Spanish silk production and manufacture; tobacco, which is also imported, hemp and flax, grown chiefly in Galicia and other northern provinces; among dye-plants, madder, saffron, woad (*Isatis tinctoria*), and wild woad or dyer's weed (*Reseda luteola*); ground-nuts (*Arachis hypogaea*), grown for their oil, for the preparation of which the nuts are exported in considerable quantity to France; liquorice, cummin, colocynth, &c. Esparto, chiefly from the arid lands of the south-east, is largely exported to Great Britain.

Vegetables.

Despite all the efforts of the breeders and of the government, a decline has gone on not only in horse-rearing, but also in other classes of livestock since 1865. Among the causes assigned for this decay is the fact that horse, sheep, goat and swine rearing is becoming less remunerative. Heavy taxation, aggravated by unequal distribution of the burden, owing to insufficient survey of the assessable property, has also contributed to the decline of this and other branches of Spanish farming.

Livestock.

The only animals belonging to Spain still noted for their excellence are mules and asses, which are recognized as among the best to be found anywhere. Goats are mostly bred in the mountainous districts all along the Spanish side of the Pyrenees from Biscay to Catalonia, and in Badajoz, Cáceres, Ciudad Real, Granada and Leon; swine in Badajoz, Lugo, Oviedo, Cáceres and Corunna. The pork and hams of Estremadura are famous; goats' milk and cheese are important articles of diet. In some districts a single peasant often owns as many as 3000 head of goats. Besides the cattle reared for field-labour and (in the northern provinces) for regular dairy farming, bulls for bull-fighting are specially reared in many parts of the country, particularly in the forests of Navarre, the mountains separating the two Castiles, the Sierra Morena, and the Serrania de Ronda in Granada, and also in separate enclosures on the islands of the Guadalquivir. Spanish sheep, which once formed so important a part of the national wealth, are far from having the same importance at the present day. The most famous breeds of Spanish sheep are the merinos or migrating sheep, which once brought immense revenues to the state as well as to the large proprietors to whom they mostly belonged (see MERINO). These sheep are pastured in different districts in summer and winter. Their winter quarters are in the lower parts of Leon and Estremadura, La Mancha, and the lowlands of Andalusia, their summer quarters the more mountainous districts to the east and north (Plasencia in the province of Cáceres, Ávila, Segovia, Cuenca, Valencia), which are not so much affected by the summer droughts of the Peninsula. The mode of the migration and the routes to be followed are prescribed by law. Each flock consists of about 10,000 sheep, under the command of a *mayoral*, and is divided into sections containing about 1000 each, each section under the charge of an overseer (*capataz*), who is assisted by a number of shepherds (*pastores*) attended by dogs. The shepherds, rudely clad in a sleeveless sheepskin jacket, the wool outside, and leather breeches, and loosely wrapped in a woollen mantle or blanket, are among the most striking objects in a Spanish landscape, especially on the table-land. The migration to the summer quarters takes place at the beginning of April, the return at the end of September. At one time the owners of merino flocks enjoyed the right of pasturing their sheep during their migrations on a strip of ground about 100 yds. in breadth bordering the routes along which the migrations took place, but this right (the *mesta*, as it was called) was abolished in 1836 as prejudicial to cultivation. The numbers of the merinos have been greatly reduced, and they have been replaced by coarse-woolled breeds.

Fisheries.—The catching of tunnies, sardines, anchovies and salmon on the coasts employs large numbers of fishermen (about 67,000 in 1910), and the salting, smoking and packing of the first three give employment to many others. In 1910 there were about 400 sardine-curing establishments in the kingdom.

Minerals.—The mineral resources of Spain are as yet far from being adequately turned to account. No European country produces so great a variety of minerals in large amount, and in the production of copper ore, lead ore and mercury Spain heads the list. In the production of salt and silver it is excelled only by Austria-Hungary, and, as regards silver, not always even by it. Iron ore is chiefly obtained in Biscay and Murcia, the former yielding by far the greater quantity, but the latter yielding the better quality.

All except a small fraction of the copper ore is obtained from the province of Huelva, in which lie the well-known mines of Tharsis and Rio Tinto (*q.v.*). The lead ore is obtained chiefly in Murcia and Jaen. The famous mines of Linâres belong to the latter province. Argentiferous lead is chiefly produced in Almería, which also produces most of the silver ore of other kinds except argentiferous copper ore, which is entirely obtained from Ciudad Real. The still more celebrated mercury mines of Almaden (*q.v.*), the richest in the world till the discovery of the Californian mines of New Almaden, belong to Ciudad Real, and this province, together with that of Oviedo, furnishes the whole of the Spanish production of this mineral. Spanish salt is partly marine, partly derived from brine-springs and partly from rock-salt, of which last there is an entire mountain at Cardona (*q.v.*) in Barcelona. Coal is chiefly obtained in Oviedo, Palencia and Cordova. The production is quite insignificant compared with the extent of the coal-bearing beds, which are estimated to cover an area of about 3500 sq. m., of which nearly a third belongs to Oviedo. Among the less important Spanish minerals are manganese (chiefly in Ciudad Real), antimony, gold, cobalt, sodic sulphate, sulphate of barium (barytes), phosphorite (found in Cáceres), alum, sulphur, kaolin, lignite, asphalt, besides a variety of building and ornamental stones. In 1905 the workmen employed on mines in Spain numbered 105,000, and the total value of the output was estimated at £7,734,805. By the law of the 6th of July 1859, a large number of important mines, including all the salt-works and rock-salt mines, were reserved as state property, but financial necessities compelled the government to surrender one mine after another, so that at present the state possesses only the mercury mines and some salt-works. Many of the mines have been granted to foreign (principally British) companies.

Manufactures.—The maritime provinces, being those most favourably situated for the import of coal, and, where necessary, of raw material, are the chief seats of Spanish manufactures. The principal manufacture is that of cotton. The exports of Spanish cotton goods were, until the close of the 19th century, hardly worth mentioning outside the colonial markets, which took an average of two millions sterling in the decade 1888–1898. This outlet is now almost closed, as the new masters of Cuba, Porto Rico and the Philippines no longer protect Spanish imports against European and American competitors. But this loss has been to a great extent compensated by the expansion of the home market for cotton, and the Spanish manufacturers are unable to meet the wants of the population, large quantities of cotton goods being imported every year. The cotton industry was long principally centred in Catalonia, and mainly in the province and town of Barcelona, famed also for their manufactures of lace, woollen and linen goods. The northern provinces, especially Guipúzcoa and Biscay, Navarre and Oviedo, have followed in the wake of Catalonia for linen and cotton industries and for paper-mills. Flax-spinning is confined to Galicia. The silk industry, though inadequate to meet the home demands, is active in Valencia, Murcia and Seville. Metal industries, at first limited to the Basque Provinces, particularly around Bilbao, have spread to Asturias, Almería, Galicia, near the great ore beds and in the vicinity of many coal mines. In the same Asturian districts the government has its foundries and factories for making arms at La Trubia and Oviedo, Toledo being only now famous for its blades and decorative work, while the foundries at Seville and Segovia are unimportant compared with those of Asturias. The manufacture of leather, another Spanish industry of old renown, is still extensively carried on in Catalonia and elsewhere, but the making of *cordwain* has long ceased to be a speciality of Cordova, from which it takes its name. Gloves are made in Seville and Madrid, shoes in the Balearic Isles, chiefly for Cuba and Porto Rico. The esparto is twisted into cords and ropes and the staple matting so common on the floors of Spanish houses of all classes, the *estera*. Soap, chocolate and cork manufactures are among the prosperous industries. The same may be said of charcoal, both for heating and mechanical purposes. The large furnaces for the distillation of mercury at Almaden were at one time heated solely with charcoal obtained from the *Cistus ladaniferus*. The making of porcelain is chiefly carried on at Seville. The war of tariffs between France and Spain after 1891 was an inducement for an extraordinary development in the making of brandy and liqueurs of every kind, of fruit preserves, potted meats, etc., in Navarre, the Basque Provinces, Catalonia, and even in Valladolid and Andalusia. Special mention must be made of the manufacture of tobacco, a royal monopoly, farmed out to a company, which increased the factories from seven to twelve and began by paying the treasury £3,400,000 annually.

The decade following the Spanish-American War (1898–1908), which may be regarded as a period of industrial and commercial reconstruction, was marked by a very rapid increase in the use of electricity for lighting, traction and other purposes. Owing to the abundance of water-power to be obtained in the mountainous regions, these new undertakings proved very successful. Spain is, on the whole, a country whose production falls far short of her own requirements. With a protected home market, cheap power and cheap labour available, there is room for much industrial development. It is, however, noteworthy that Spanish capitalists are, as a class, though exclusive of the Catalans, unduly conservative. Hence the capital for the establishment of electrical industries was almost exclusively subscribed in Germany, France, Belgium, Switzerland and the United States, just as, in the 19th century, the railways and mining industries had been mainly financed by British investors, and the Valencian silk industry by French. Another feature of the period of reconstruction was the formation of numerous trusts or combinations of producing companies designed to take advantage of the high tariff, and to restrict competition, lower expenses and raise prices. The paper, sugar, salt petroleum and metallurgical industries were subjected to this process, but in no case was it possible to secure a complete monopoly.

Commerce.—Possessing varied resources and being favourably situated for commerce, Spain might be expected to take a leading place among the trading communities of Europe. This it did at one time hold, when the treasure acquired by the discovery of America and the conquest of Mexico and Peru was squandered in the purchase of various commodities from England, the Netherlands and other countries. This period of outward prosperity, however, was also that in which the seeds of decline were planted. The expulsion of the Moors from Granada was contemporaneous with the discovery of the New World. Hundreds of thousands of Moors were driven out from the country on subsequent occasions, and in the act Spain lost the best of her agriculturists and handicraftsmen. The Spaniards of that day, excited by the hope of rapidly acquired wealth and the love of adventure, embarked upon a career of discovery, and agriculture and manufacturing industry fell into contempt. The loss of all her possessions on the American mainland in the early part of the 19th century dealt a severe blow to the foreign commerce of Spain, from which it only recovered about 1850, when imports and exports began to increase. After the restoration of the Bourbons in 1875, the first cabinet of Alphonso XII.'s reign stopped the operation of the tariff law of the Revolution and reverted to protection. In 1882 a Liberal cabinet revived the system of a gradual reduction of import duties to a fixed maximum, and made commercial treaties with France and several other nations, which were followed by a treaty with Great Britain in 1886. The foreign commerce of Spain rapidly developed in the decade 1882–1892, Great Britain, France and the United States figuring at the head of the imports, Great Britain and France at the head of the exports. The exports of Spanish wines to France alone amounted to £12,000,000 annually. When France and other European nations abandoned free trade for protection towards 1890, a strong movement set in in Spain in favour of protection. In 1890 the Conservative cabinet of Señor Canovas raised the duties on agricultural products, in 1891 it denounced all the treaties of commerce that included most-favoured-nation treatment clauses, and in 1892 a new tariff law established considerably higher duties than those of 1882—in fact, duties ranging from 40% to 300%. The subsequent revision of the tariff, completed in 1906, involved no serious departure from the economic policy adopted in 1890.

The following table shows the value of Spanish imports and exports for a number of representative years after 1848:—

Year.	Imports.	Exports.
	£	£
1849	6,360,000	5,240,000
1860	14,833,000	10,982,000
1865	16,262,000	12,864,000
1870	20,876,000	15,982,000
1875	22,812,000	18,081,000
1880	28,482,000	25,999,000
1885	30,590,000	27,920,000
1890	37,646,000	37,510,000
1895	33,540,000	32,198,000
1900	34,496,000	28,955,000
1905	32,320,000	50,012,000

The principal exports include metals and other minerals; wine, sugar, fruit and other alimentary substances, cotton and its manufactures; animals and their products, including wool and hair; timber and wrought wood. The principal imports include grain, dried fish and other food-stuffs; livestock and animal products; machinery, vehicles and ships; stone, minerals, glass and pottery; drugs and chemical products; textiles and raw cotton. Great Britain, France, the United States, Germany and Portugal, named in the order of their importance, are the chief consumers of Spanish exports. The chief exporters to Spain (in the same order) are Great Britain, France, Cuba, Germany and Portugal. The foreign trade of the country is of course carried on mainly by sea, and of the land commerce by far the largest proportion is with or through France. The smallness of the trade with Portugal is partly due to the similarity of the chief products of the two countries.

Shipping and Navigation.—Spain has 21 seaboard provinces, with more than 120 ports of some importance. The merchant navy of Spain, far from decaying through the loss of her colonies in 1898, seems to have been given fresh impetus. Many English and French steamers have been purchased abroad and nationalized. In 1905 the mercantile marine comprised 449 steamships of 434,846 tons, and 541 sailing vessels of 85,583 tons. The sailing vessels are decreasing in numbers in the exterior trade, but not in the coasting trade, which is decidedly developing and occupying more craft. It is carried on exclusively under the Spanish flag. The fishing fleet, chiefly sailing boats, is also important, and is manned by a hardy and active coast population. In 1905 19,722 ships of 16,595,267 tons entered, and 18,033 of 16,442,355 tons cleared.

Banking and Credit.—The Bank of Spain (Banco de España) has a charter which has been renewed and enlarged several times since its foundation after the Restoration, and its privileged note issue has had to be gradually and very largely increased by legislative authorizations, especially in 1891 and 1898, as its relations with the treasuries of Spain and of her colonies increased; since nothing in the services rendered by the bank to the public would ever have justified the growth of the note issue first to thirty millions sterling in 1891, then by quick strides to fifty and over sixty-one millions sterling in 1899 and 1900. At the close of the 19th century the remodelled bank charter, which is only to expire in 1921, authorized a maximum issue of £100,000,000, on condition that the bank keeps cash in hand, gold and silver in equal quantities, equal to a third of the notes in circulation up to £60,000,000, and equal to half the amount issued above that sum. Gold has practically disappeared from business of every kind since 1881, when the premium began to rise; it reached a maximum of 120% during the war with America. Afterwards it dropped to about 30 in 1900. Bank-notes and silver coin have been practically the currency for many years.

Currency, Weights and Measures.—The metric system of weights and measures was officially adopted in Spain in 1859 and the decimal monetary system in 1871. In the case of the weights and measures the French names were also adopted, with only the necessary linguistic changes. Certain older standards remain in common use, notably the *quintal* (of 101·4 ℔ avoirdupois), the *libra* (1·014 ℔ avoirdupois), the *arroba* ($3\frac{1}{2}$ imperial gallons for wine, $2\frac{3}{4}$ imperial gallons for oil), the *fanega* ($1\frac{1}{2}$ imperial bushels). In the case of the currency the old Spanish name of *peseta* was retained for the unit (the franc, $9\frac{1}{2}$d.). The *peseta* is divided into 100 *centesimos.* According to its par value 25·225 pesetas are about equal to £1, but the actual value of the peseta is about $7\frac{1}{2}$d. In law, there is a double standard of value, silver and gold, in the ratio of $15\frac{1}{2}$ to 1. But the only silver coin which is legal tender up to any amount is the 5-peseta piece, and the coinage of this is restricted. One-peseta pieces in silver, and 20-, 10- and 5-peseta pieces in gold are also current. Before the introduction of the decimal monetary system the peseta was the fifth part of a *peso duro*, which was equal to 20 *reales de vellon*, or rather more than a 5-franc piece. The only paper money consists of the notes of the Bank of Spain.

Finance.—Spanish finance passed through many vicissitudes during the 19th century. In the reigns of Ferdinand VII. and Isabella II. the creditors of the state had to suffer several suspensions of payments of their dues, and reductions both of capital and interest. During the Revolution, from 1868 to 1874, matters culminated in bankruptcy. Payments of interest were only in part resumed after the Restoration in 1876, and in 1882 the government of King Alphonso XII. proposed arrangements to consolidate the floating and treasury debts of the Peninsula in the shape of £70,000,000 of 4% stock, redeemable in 40 years, and to reduce and consolidate the old exterior and interior debts, then exceeding £480,000,000, in the form of £78,840,000 of exterior 4% debt—exempt from taxation under an agreement to that effect with the council of foreign bondholders in London on the 28th of June 1882—and £77,840,000 of perpetual interior 4%. The colonial debts were not included in those plans. The debts of Spain were further increased in 1891 by a consolidation of £10,000,000 of floating debt turned into 4% redeemable stock similar to that of 1882; and this did not prevent a fresh growth of floating debts out of annual deficits averaging two to three millions sterling during the last quarter of the 19th century. The floating debt in 1900 had swollen to £24,243,300. The government of Spain having guaranteed the colonial debts of Cuba and of the Philippines, when those colonies were lost in 1898, Spain was further saddled with £46,210,000 of colonial consolidated debts, and with the expenses of the wars amounting, besides, to £63,257,000. Consequently, the Spanish government had once more to attempt to make both ends meet by asking its creditors to assent to the suppression of all the amortization of imperial and colonial debts, and to a tax of 20% on the coupons of all the debts, whilst at the same time the Cortes were asked to authorize a consolidation and liquidation of the floating and war debts and an annual increase of £3,200,000 in already heavy taxation. Under these modifications the Spanish debt at the close of the 19th century, exclusive of £44,000,000 of treasury debt, consisted of £41,750,000 of exterior debt, still temporarily exempted from taxation on the condition of being held by foreigners, of £270,000,000 of 4% interior consols, and of £60,000,000 of new 5% consols, replacing the war and floating debts. In January 1905 this total outstanding debt of £415,750,000 had been reduced to £381,833,000; the capital sum was thus approximately equal to £20 8s. per head of the population, and the annual charge amounted to about 17s. 6d. per head. Between 1885 and 1905 the revenue of Spain varied from £30,000,000 to £40,000,000, and the expenditure was approximately equal; deficits were common towards the beginning of this period, surpluses towards the end. For an analysis of the budget the year 1908 may be taken as typical, inasmuch as trade had then resumed its normal condition, after the disturbing influence of tariff revision in 1906 and the failure of many crops in 1907. The estimates for 1908 showed that the revenue was derived as follows: Direct taxes on land, houses, mines, industry and commerce, livestock, registration acts, titles of nobility, mortgages and salaries paid by the state, £18,020,800; indirect taxes, including customs, excise, tolls and bridge and ferry dues, £14,748,000; tobacco monopoly, lottery, mint, national property, balance from public treasury, &c., £8,858,400; total £41,627,200. The principal items of expenditure were: Public debt, £16,199,300; ministry of war, £6,301,100; ministry of public works, &c., £3,679,540; pensions, £2,881,400. The total was £40,926,740.

Constitution and Government.—Spain is an hereditary monarchy the constitution of which was voted by the Cortes and became the fundamental law of the 30th of June 1876. This law fixes the order of succession as follows: should no legitimate descendant of Alphonso XII. survive, the succession devolves first upon his sisters, next upon his aunt and her legitimate descendants, and finally upon the legitimate descendants of the brothers of Ferdinand VII. "unless they have been excluded." Should all lines become extinct, the nation may elect its monarch. The sovereign becomes of age on completing his or her sixteenth year. He is inviolable, but his ministers are responsible to the Cortes, and none of his decrees is valid unless countersigned by a minister. The sovereign is grand-master of the eight Spanish orders of knighthood, the principal of which is that of the Golden Fleece (Toison de Oro), founded in 1431 by Philip of Burgundy. The chain of this order surrounds the royal arms, in which are included, besides the arms of Castile, Leon, Granada, and the lilies of the royal house of Bourbon, the arms of Austria, Sicily, Savoy, Brabant and others. The national colours are red and yellow. The flag is divided into three horizontal stripes, two red stripes with a yellow one between bearing the royal arms.

The legislative authority is exercised by the sovereign in conjunction with the Cortes, a body composed of two houses—a senate and a chamber of deputies. The senate is composed of members of three classes: (1) members by right of birth or office—princes, nobles who possess an annual income of 60,000 pesetas (£2,400), and hold the rank of grandee (*grande*), a dignity conferred by the king either for life or as an hereditary honour, captains-general of the army, admirals of the navy, the patriarch of the Indies, archbishops, cardinals, the presidents of the council of state or of the Supreme Court, and other high officials, all of whom must have retained their appointments for two years; (2) members nominated by the sovereign for life; and (3) members elected three each by the 49 provinces of the kingdom, and the remainder by academies, universities, dioceses and state corporations. The members belonging to the first two classes must not exceed 180 in number, and there may be the same number of members of the third class. The senatorial electors in the provinces are (1) delegates of the communes and (2) all the members of the provincial council, presided over by the governor. The lower house of the Cortes was elected by a very limited franchise from 1877 to 1890, when the Cortes passed a reform bill which became law on the 29th of June 1890. This law re-established universal male suffrage, which had existed during the Revolution, from 1869 to 1877. Under the law of the 29th of June 1890 every Spaniard who is not debarred from his civil and civic rights by any legal incapacity, and has resided consecutively two years in his parish, becomes an elector on completing his twenty-fifth year. Soldiers and sailors in active service cannot vote. All Spaniards aged 25 who are not clerks in holy orders can be elected. The same electoral law was extended to the municipal elections.

The executive administration is entrusted to a responsible ministry, in which the president generally holds no portfolio, though some prime ministers have also taken charge of one of the departments. The ministerial departments are: Foreign affairs, grace and justice, finance, interior, war, education and fine arts, marine, public works, and agriculture and commerce. Under the secretary of state for the interior the civil administration in each province is headed by a governor, who represents the central power in the provincial council (*diputacion provincial*) which is also elected by universal suffrage. The provincial councils meet yearly, and are permanently represented by a committee (*commission provincial*), which is elected annually to safeguard their interests. Every commune or municipality has its own elected *ayuntamiento* (*q.v.*), which has complete control over municipal administration, with power to levy and collect taxes. Its members are styled *regidores* or *concejales*, and half their number is elected every two years. They appoint an *alcalde* or mayor from among themselves to act as president, chief executive officer, and justice of the peace. In the larger towns the alcalde shares his reponsibilities with several permanent officials called *tenientes alcaldes*. The fundamental law of 1876 secures to ayuntamientos, and to the provincial councils, an autonomy which is complete within its own limits. Neither the executive nor the Cortes may interfere with provincial and communal administration, except when the local authorities exceed their legal power to the detriment of public interests. This provision of the constitution has not always been strictly observed by the government.

Law and Justice.—Spanish law is founded on Roman law, Gothic common law, and the national code proclaimed at the meeting of the Cortes at Toro in 1501 (the *leyes de Toro*).

The present civil code was put into force on the 1st of May 1889 for the whole kingdom. The penal code dates from 1870, and was modified in 1877. The commercial code was put into force on the 22nd of August 1885, the code of civil procedure on the 1st of April 1881, and the code of criminal procedure on the 22nd of June 1882. There is a court of first instance in each of the 495 *partidos judiciales*, or legal districts, into which the kingdom is divided. From this inferior jurisdiction the appeals go to the 15 *audiencias territoriales*, or courts of appeal. There is in Madrid a Supreme Court, which is modelled upon the French Cour de Cassation, to rule on points of law when appeals are made from the decisions of inferior courts, or when conflicts arise between civil and military jurisdiction. When the law of the 20th of April 1888 established trial by jury for most crimes and delicts, 49 *audiencias criminales*, one in each province, were created; these are a sort of assize held four times a year. The administration of justice is public. The parties to a suit must be represented by counsel. The state is always represented in every court by *abogados fiscales*, public prosecutors, and counsel who are nominees of the Crown.

Religion.—Roman Catholicism is the established religion, and the Church and clergy are maintained by the state at an annual cost of about £1,600,000. The relations between Church and state, and the position of the religious orders, were defined by the concordat of 1851, remaining practically unchanged until 1910. There are ten archbishoprics (Toledo, Madrid, Burgos, Granada, Santiago, Saragossa, Seville, Tarragona, Valencia and Valladolid) and forty-five bishoprics. The archbishop of Toledo is primate. The number of monastic communities is about 3250, including some 600 convents for men and 2650 for women. Most of the religious orders carry on active educational or charitable work. The monks number about 10,000, the nuns 40,000. The immense majority of the people are professed adherents of the Roman Catholic faith, so that, so far as numbers go, Spain is still the most "Catholic" country in the world, as it has long been styled. With liberty of conscience during the Revolution, from 1868 to 1877, the Church lost ground, and anti-clerical ideas prevailed for a while in the centres of republicanism in Catalonia and Andalusia; but a reaction set in with the Restoration. The governments of the Restoration showed the Church much favour, allowed the Jesuits and religious orders of both sexes to spread to an extent without precedent in the century, and to take hold of the education of more than half of the youth of both sexes in all classes of society. This revival of Church and monastic influence began during the reign of Alphonso XII., 1877–1885, and considerably increased afterwards under the regency of Queen Christina, during the long minority of Alphonso XIII., the godson of Pope Leo XIII. Spanish codes still contain severe penalties for delicts against the state religion, as writers frequently discover when they give offence to the ecclesiastical authorities. Blasphemy is punished by imprisonment. The bishops sit in the superior council of education, and exercise much influence on public instruction. Since 1899 all boys have been obliged to attend lectures on theology and religion during six out of seven years of their curriculum to obtain the B.A. degree. Canon law and Church doctrine form an obligatory part of the studies of men qualifying for the bar and magistracy. By the constitution of 1876 non-Catholics were only permitted to exercise their form of worship on condition that they did so in private, without any public demonstration or announcement of their services. The same rule applies to their schools, which are, however, numerously attended, in Madrid, Seville, Barcelona and other towns, by children of Protestant families and of many Roman Catholics also. A proposal to abolish these restrictions was made by the government in 1910 (see *History*, below).

Education.—A law of the 17th of July 1857 made primary education free for the poor, and compulsory on all children of school age, originally fixed at six to nine years. It proved impossible to enforce this statute, and the majority of Spaniards are still illiterate, though in decreasing proportion at each census. The primary schools for both sexes are kept up by the municipalities, at an annual cost of about £1,000,000, to which the state contributes a small subvention. The secondary schools, of which there must be at least one in every province, are styled institutes and are mostly self-supporting, the fees paid by the pupils usually cover the expenses of such establishments, which also receive subsidies from some of the provincial councils. Spain has nine universities: Madrid, the most numerously attended; Salamanca, the most ancient; Granada, Seville, Barcelona, Valencia, Santiago, Saragossa and Valladolid. There are also a faculty of medicine at Cadiz and a faculty of law at Oviedo. Most of the universities are self-supporting from the fees of matriculations and of degrees. The state also maintains a variety of technical schools, for agriculture, engineering, architecture, painting, music, &c. The whole system of public instruction is controlled by the minister of education and an advisory council. A law passed on the 1st of July 1902 requires that all private schools must be authorized by the state, and arranges for their periodical inspection, for the enforcement of proper sanitation and discipline, and for the appointment of a suitable staff of teachers. Among the institutions affected by this law are numerous Jesuit and other ecclesiastical schools for boys, and a Jesuit university at Deusto, near Bilbao, whose pupils have to pass their final secondary examinations and to take all degrees in the state establishments as free scholars. The education of girls has been much developed not only in the state schools but even more so in the convents, which educate more than half the girls of the upper and middle classes. Many girls attend the provincial institutes, and some have successfully gone in for the B.A. degrees and even higher honours in the universities.

Defence.—The Spanish army is recruited by conscription. Liability to service begins with the first day of the calendar year in which the twentieth year is completed. Except in extraordinary circumstances, the war ministers have seldom called for more than forty to sixty thousand men annually, and of this contingent all who can afford to do so buy themselves off from service at home by payment of £60, and if drafted for colonial service by payment of £80. The period of service for all arms is twelve years—three with the colours, three in the first-class reserve, six in the second-class reserve, which contains the surplus of the annual contingent of recruits, and is liable to one month's training in every year. The war ministers can, and frequently do, send on unlimited furlough, or place in the first-class reserve, men who have not completed their first three years, and thus a considerable saving is made. Brothers can take each other's place in the service, and eldest sons of aged parents, or sons of widows, easily get exempted. Spain is divided into seven military regions or army corps. The strength of the regular army for many years varied between 85,000 and 100,000 in time of peace, and during the Carlist Wars, 1868 to 1876, Spain had 280,000 under arms, and nearly 350,000 during her more recent wars. For 1899–1900 the figures were only 80,000. The active army is divided into 56 regiments of the line with 2 battalions each, 20 battalions of rifles or cazadores, 2 Balearic Islands, 1 Melilla, 4 African battalions of light infantry, 2 battalions of rifles in the Canaries. The cavalry includes a squadron of royal horse guards, 28 regiments of the line, remount and dépôt establishments, 4 regional squadrons in Majorca, the Canaries, Ceuta, Melilla. The artillery comprises 12 regiments of field artillery, 1 of horse artillery, 3 regiments and an independent division of mountain guns, and 7 battalions of garrison artillery. The royal engineers are 4 regiments of sappers and miners, 1 of pontooners, 1 battalion of telegraph engineers, 1 of railway engineers with cyclists, 1 balloon corps, and 4 colonial corps. Other permanent military forces are 1075 officers, 1604 mounted and 16,536 foot gendarmes, mostly old soldiers, and 14,156 carabineers, all of them old soldiers. The regular army, at the close of the wars in 1898, had 26,000 officers and about 400 generals, but a law was afterwards made to reduce their numbers by filling only one out of two death vacancies, with a view to reach a peace establishment of 2 marshals, 25 lieutenant-generals, 50 divisional- and 140 brigadier-generals, and 15,000 officers. The total strength of the field army may be estimated at 220,000 combatants. The military academies are Toledo for infantry, Segovia for artillery, Valladolid for cavalry, Ávila for commissariat, Escorial for carabineers, Getafe for civil guards, besides a staff college styled Escuela Superior de Guerra at Madrid. Numerous fortresses guard the Portuguese frontier and the passes of the Pyrenees, but many of these are ill-armed and obsolete.

The navy is recruited by conscription in the coast or maritime districts, which are divided into three naval captaincies-general, those of Ferrol, Cadiz and Cartagena—at the head of each being a vice-admiral. No attempt was made, during the decade which followed the Spanish-American War, to replace the squadrons destroyed at Manila and Santiago de Cuba. When the reconstruction of the navy was begun, in 1908, Spain possessed 1 battleship, 2 armoured cruisers, 6 protected cruisers, 5 destroyers and 6 torpedo-boats. All the larger vessels were old and of little value.

Bibliography.—The following works are mainly topographical and descriptive: G. H. Borrow, *The Bible in Spain* (1st ed., London, 1843; with notes and glossary by Ulick R. Burke, London, 1899); Madoz, *Diccionario geográfico-histórico y estadístico de las provincias de España* (16 vols., 1846–1850); F. Coello, *Reseña geográfica, geológica, y agrícola de España* (Madrid, 1859); W. Webster, *Spain* (London, 1882); M. Willkomm, *Die pyrenäische Halbinsel* (3 vols., Leipzig, 1884–1886); E. de Amicis, *Spagna* (Florence, 1885; Eng. trans. *Spain and the Spaniards*, New York, 1885); R. del Castillo, *Gran diccionario geográfico de España* (4 vols., Barcelona, 1889–1892); R. Bazin, *Terre d'Espagne* (Paris, 1895); E. Pardo Bazán, *Por la España pintoresca* (Barcelona, 1895); R. Foulché-Delbosc, *Bibliographie des voyages en Espagne* (Paris, 1896); H. Gadow, *In Northern Spain* (London, 1897); J. Hay, *Castilian Days* (2nd ed., London, 1897); W. J. Root, *Spain and its Colonies* (London, 1898); K. L. Bates, *Spanish Highways and Byways* (London, 1900); A. J. C. Hare, *Wanderings in Spain* (8th ed., London, 1904); R. Thirlmere, *Letters from Catalonia* (2 vols., London, 1905). Valuable information can be obtained from the *Boletins* of the Madrid Geographical Society. *España, sus monumentos y artes, su naturaleza e historia* is an illustrated series of 21 volumes by various writers (Barcelona, 1884–1891). The "Spanish Series" of monographs on towns and cities, edited by A. F. Calvert (London, 1906, &c.), is noteworthy for descriptions of architecture and painting, and for the excellence of its many illustrations. The best guide-books are H. O'Shea, *Guide to Spain and Portugal* (London, 1899); R. Ford, *Murray's Handbook for Spain* (2 vols., London, 1906); and C. Baedeker, *Spain and Portugal* (Leipzig, 1908). *Stieler's Handatlas* (Gotha, 1907) contains the best maps for general use. The *Mapa topográfica de España*, published by the Instituto geográfico y estadístico de España in 1080 sheets, is on the scale of 1 : 50,000, or 1·26 in. = 1 m.

For geology, see the maps and other publications of the Comision del Mapa Geológico de España; L. Mallada, "Explicacion del mapa geológico de España," in *Mem. com. mapa geol. Esp.* (1895, 1896, 1898 and 1902); C. Barrois, "Recherches sur les terrains anciens des Asturies et de la Galicie," in *Mém. soc. géol. du Nord*, vol. ii. (Lille, 1882); F. Fouqué, &c., "Mission d'Andalousie," in *Mém. pres. par divers savants à l'acad. des sciences*, ser. 2, vol. xxx. (Paris, 1889).

The chief authorities on flora and fauna are M. Willkomm, *Illustrationes florae hispanicae insularumque Balearium* (2 vols., Stuttgart, 1881–1892); M. Colmeiro, *Enumeración de las plantas de la Peninsula* (vol. i., Madrid, 1885), G. de la Puerto, *Botánica descriptiva*, &c. (Madrid, 1891); B. Merino, *Contribución á la flora de Galicia* (Tuy, 1897); A. Chapman and W. J. Buck, *Wild Spain* (London, 1893); id. *Unexplored Spain* (London, 1910).

Modern social and political conditions are described by G. Routier, *L'Espagne en 1897* (Paris, 1897); E. Pardo Bazán, *La España de ayer y la de hoy* (Madrid, 1899); *L'Espagne: politique, littérature, armée, &c., numéro spécial de la Nouvelle Revue Internationale* (Paris, 1900); J. R. Lowell, *Impressions of Spain* (London, 1900, written 1877–1880 when Lowell was American minister to the court of Spain); P. Gotor de Burbáguena, *Nuestras costumbres* (Madrid, 1900); R. Altamira y Creva *Psicología del pueblo español* (Madrid, 1902); V. Amirall, *El Catalanismo* (Barcelona, 1902); J. Alenda y Mira, *Relaciones de solemnidades y fiestas publicas de España* (Madrid, 1903); Madrazo, *El Pueblo español ha muerto?* (Santander, 1903); V. Gay, *Constitucion y vida del pueblo español* (Madrid, 1905, &c.); H. Havelock Ellis, *The Soul of Spain* (London, 1908).

A comprehensive account of such matters as population, industry, commerce, finance, mining, shipping, public works, post and telegraphs, railways, education, constitution, law and justice, public health, &c., may be found in the following works; all those of which the place and date of issue are not specified are published annually in Madrid: *Censo de la población de España: 1900* (Madrid, 1902, &c.); *Movimiento de la población de España;* British Foreign Office Reports (annual series and miscellaneous series, London); *Estadística general de comercio exterior de España con sus provincias de ultramar y potencias extrangeras, formada por la dirección general de Aduanas*; Annual Reports of the Council of the Corporation of Foreign Bondholders (London); *Estadística mineral de España*; *Memoria sobre las obras publicas*; *Anuario oficial de correos y telégrafos de España*; *Situación de los ferro-carriles*; *Anuario de la primera enseñanza*; H. History

A.—*Ancient to A.D. 406.*

Primitive Inhabitants.—The origin and character of the early inhabitants of the Peninsula are unknown; recent conjectures on the subject, which have been many, are more bold than probable, and we must await the result of further excavations of prehistoric sites and further inquiries into the native inscriptions before we can hope for much certainty. The Romans, whose acquaintance with the country began in the 3rd century B.C., mention three races: Iberians (in the east, north and south), Celts (north-west) and Celtiberians (centre), but the classification does not help us far. The use to-day of the strange and ancient Basque tongue on the western slopes of the Pyrenees and in Vizcaya (Biscay)—a tongue which is utterly unlike Celtic or Italian or any "Indo-Germanic" language—suggests that the Iberians may have been an older people than the Celts and alien from them in race, though the attempts hitherto made to connect Basque with ancient traces of strange tongues in the Basque lands have not yielded clear results. On the other hand, numerous place-names show that parts of the Peninsula were once held by Celtic-speaking peoples, and it is, of course, possible that Celts and Iberians may have formed a mixed race in certain regions. Of other ancient races little trace can be detected. The Phoenicians were here traders and not settlers; the Greeks, though they planted early colonies on the Gulf of Lyons, occupied hardly any site south of the Pyrenees, and the seeming likeness in name of Saguntum (*q.v.*) and the Greek island Zacynthus is mere coincidence. It is possible, however, that after the Roman conquest Italians drifted in, and it is fairly certain that after the Roman Empire fell German conquerors brought German settlers, though in what numbers no wise man will guess.

Earliest Historic Period.—Phoenician traders probably reached Spain long before our historical knowledge of the Peninsula begins, possibly as early as the 11th century B.C. One of their earlier settlements, Gades (now Cadiz), has been called the oldest town in the world (or in Europe) which has kept a continuity of life and name from its first origin. But the Phoenician exploitation of Spain dates principally from after the rise of Carthage (*q.v.*), the great Phoenician city of North Africa. Carthaginian "factories" were planted on many Spanish coasts: a Nova Carthago (New Carthage, mod. Cartagena) formed a Carthaginian fortress with the best harbour of south-eastern Spain. The expansion is attributed chiefly to the second half of the 3rd century B.C., and to the genius of the Carthaginian statesman, Hamilcar Barca, who, seeing his country deprived by Rome of her trading dominion in Sicily and Sardinia, used Spain, not only as a source of commercial wealth, but as an inexhaustible supply of warlike troops to serve in the Carthaginian armies. But Rome had already her eyes on the Spanish men and mines, and, in the second Punic War, drove Carthage finally and completely out of the Peninsula (201 B.C.).

The Phoenicians.

Roman Spain.—The Romans divided Spain into two "spheres of administration" (*provinciae*), Hither or Citerior, that is the northern districts which were nearer to Italy, and Further or Ulterior, the south. To each "province" was sent yearly a governor, often with the title *proconsul*. The commands were full of military activity. The south, indeed, and in particular the fertile valley of Andalusia, the region of the Guadalquivir (*Baetis*), then called Baetica, was from the first fairly peaceful. Settlements of Italian veterans or of Spanish soldiers who had served for Rome were made at Hispalis (Seville) and at Carteia near

Republican Period, 200-27 B.C.

Gibraltar, and a beginning was made of a Romanized provincial population, though in a somewhat half-hearted way. But in the north, on the high plateau and amidst the hills, there was incessant fighting throughout the greater part of the 2nd century B.C., and indeed in some quarters right down to the establishment of the empire. The Carthaginians had extended their influence no great distance from the eastern coast and their Roman successors had all the work to do. In the long struggle many Roman armies were defeated, many commanders disgraced, many Spanish leaders won undying fame as patriot chiefs (see NUMANTIA). Even where one Roman succeeded, the incapacity or the perfidy of his successor too often lost the fruits of success. But though its instruments were weak the Republic was still strong, and the struggle itself, a struggle quite as much for a peaceful frontier as for aggrandizement and annexation of fresh land, could not be given up without risk to the lands already won. So the war went on to its inevitable issue. Numantia, the centre of the fiercest resistance, fell in 133 B.C. before the science of Scipio Aemilianus (see SCIPIO), and even northern Spain began to accept Roman rule and Roman civilization. When in the decade 80-70 B.C. the Roman Sertorius (*q.v.*) attempted to make head in Spain against his political enemies in Rome, the Spaniards who supported him were already half Romanized. There remained only some disturbed and unconquered tribes in the northern hills and on the western coast. Some of these were dealt with by Julius Caesar, governor here in 61 B.C., who is said also to have made his way, by his lieutenant Crassus, to the tin mines of the north-west in Galicia. Others, especially the hill tribes of the Basque and Asturian mountains fringing the north coast, were still unquiet under Augustus, and we find a large Roman garrison maintained throughout the empire at Leon (*Legio*) to overawe these tribes. But behind all this long fighting, pacification and culture had spread steadily. The republican administration of Spain was wise. The Spanish subjects were allowed to collect themselves the taxes and tribute due to Rome, and, though the mineral wealth doubtless fell into the hands of Roman capitalists, the natives were free from the tithes and tithe system which caused such misery and revolt in the Roman province of Sicily. On the other hand, every facility was given them to Romanize themselves; there was no competing influence of Hellenic or Punic culture and the uncivilized Spaniards accepted Roman ways gladly. By the days of Cicero and Caesar (70-44 B.C.) the southern districts, at least, had become practically Roman: their speech, their literature, their gods were wholly or almost wholly Italian, as Cicero and Strabo and other writers of these and the next few years unanimously testify. Gades, once Phoenician, gained, by Caesar's favour and the intercession of Balbus, a Roman municipal charter as *municipium*: that is, its citizens were regarded as sufficiently Romanized to be granted both the Roman personal franchise and the Roman city-rights. It was the first city outside of Italy which obtained such a municipal charter, without the usual implantation of Roman citizens (either poor men needing land or discharged veteran soldiers) from Italy.

The Empire, 27 B.C.-A.D. 406.

Augustus (or Tiberius possibly) reorganized the administration of Roman Spain. Henceforward there were three provinces: (*a*) the north and north-west, the central table-land and the east coast as far south as New Carthage, that is, all the thinly-populated and unquiet hill country, formed the province of Tarraconensis with a capital at Tarraco (Tarragona) under a *legatus Augusti pro praetore* with a legion (VII. Gemina) at Leon and some other troops at his disposal; (*b*) the fertile and peaceful west formed the province of Lusitania, very roughly the modern Portugal, also under a *legatus Augusti pro praetore*, but with very few troops; (*c*) the fertile and peaceful south formed the province of Baetica, called after its chief river, the Baetis, under a proconsul nominated by the senate, with no troops. These divisions (it will be observed) exactly coincide with the geographical features of the Peninsula. Substantially, they remained till the end of the empire, though Tarraconensis was broken up at different dates into smaller and more manageable areas. Augustus also accelerated the Romanization of the land by planting in it many municipalities (*coloniae*) of discharged soldiers, such for example as Augusta Emerita (mod. Mérida), which declares by its name its connexion with time-expired veterans and still possesses extensive Roman ruins. Either now, too, or soon after, imperial finance agents (*procuratores*) were appointed to control the revenues and also to look after the mines, which now became Imperial property, while a special *praefectus* administered the Balearic Islands. The two principal features of the whole country during the imperial period are its great prosperity and its contributions to Roman literature. Shut off from foreign enemies (though occasionally vexed by pirates from Africa), secluded from the wars of the empire, it developed its natural resources to an extent unequalled before or since. Its iron and copper and silver and lead were well known: it was also (according to the elder Pliny) the chief source whence the Roman world obtained its tin and quite outdistanced in this period the more famous mines of Cornwall. But such commercial prosperity characterized many districts of the empire during the first two centuries of our era. Spain can boast that she supplied Rome with almost her whole literature in the silver age. The Augustan writers had been Italians. When they passed away there arose in their places such writers as the younger Seneca, the epic poet Lucan, the epigrammatist Martial, the literary critic Quintilian, besides a host of lesser names. But the impulse of the opening empire died away and successful commerce drove out literary interests. With the 2nd century the great Roman-Spanish literature ceased: it was left to other regions which felt later than Spain the stimulus of Romanization to enter into the literary tradition. Of statesmen the Peninsula was less prolific. The emperor Trajan, indeed, and his relative and successor Hadrian, were born in Spain, but they were both of Roman stock and Roman training. The 3rd and 4th centuries saw a decline in the prosperity of Roman Spain. The confiscations of Septimus Severus and the ravages of barbarians in the middle of the 3rd century have both been adduced as causes for such a decline. But while we need not doubt that the decline occurred, we can hardly determine either its date or its intensity without careful examination of the Roman remains of Spain. Many of the best Roman ruins—such as the aqueduct of Segovia or the bridge of Alcantara—no doubt date from before A.D. 200. Others are probably later, and indicate that prosperity continued here, as it did on the other side of the Pyrenees in Gaul, till the later days of the 4th century—perhaps indeed not till the fatal winter's night in 406-7 when the barbarians burst the Rhine frontier and flooded Gaul and even Spain with a deluge from which there was no recovery. (F. J. H.)

B.—*From A.D. 406 to the Mahommedan Conquest.*

The Barbarian Invasion and the Visigothic Kingdom.—With the irruption of the Vandals, the Suebi and the Alans, the history of Spain enters on a long period of division and confusion which did not end even with the union of the chief kingdoms by the marriage of Isabella and Ferdinand at the close of the 15th century. The function of the barbarians everywhere was to cut the communications of commerce, and the nerves of the imperial administration, thereby throwing the invaded country back into a fragmentary condition from which a new order was to arise in the course of centuries.

Vandals and Suebi.

This function was effectually discharged in Spain by the Vandals and their associates, who plundered far and wide, and then by the Visigoths, who appeared as the "foederati," or duly commissioned defenders of the Romans. The first-comers cannot be said to have conquered the country in the sense that they established a rule of their own. They were not numerous enough for the execution of such a task, even if they had possessed the capacity. When in 428 Gaiseric, king of the Vandals (*q.v.*), accepted the invitation of Bonifacius, the count of Africa, and passed out of Spain to found the Vandal kingdom of Carthage, his whole horde numbered only 80,000 persons, including old men, women and children, and runaway slaves who had joined him. The Suebi, who remained, were certainly not more numerous. Such small bodies could not have occupied so extensive a territory, even if they had scattered themselves in driblets all over its surface. What they did was to rove about in hordes, plundering or levying blackmail. The cowed inhabitants had been trained out of all habit of acting for themselves hy the imperial despotism, and could only flee or submit. There is probably some truth in the assertion of Salvian that many of the subjects of the empire preferred poverty among the barbarians to the tyranny of the imperial tax collectors. This would be preeminently the case with the smaller landowners who formed the "curiales," and who were in reality serfs of the fisc, for on them fell the main weight of taxation, and they were confined to their position by oppressive laws. The great landowners who formed the "ordo senatorius" had almost as much to fear from the agrarian insurgents known as *bagaudae*, who are indeed found acting with the Suebi, as from the barbarians. In time some of them took to "living barbarously"—that is to say, they fortified their villas, collected an armed following and fought for their lives, families and property. In some districts the inhabitants reverted to a state of tribal independence. This undoubtedly was the case in the north, where the Asturians and Basques, the least Romanized part of the population, appear from the beginning of the age of barbarization as acting for themselves. In the mountain country of Cuenca, Albacete, and the Sierra Nevada the natives known as the Orospedans were entirely independent in the middle of the 6th century. But if there lay in this revival of energy and character the germs of a vigorous national life, for the time being Spain was thrown back into the state of division from which it had been drawn by the Romans—with the vital difference that the race now possessed the tradition of the Roman law, the municipalities, and one great common organization in the Christian Church.

Visigothic Occupation.

No help was to be expected from the empire. Unable to aid itself it had recourse to the Visigoths (see GOTHS). Ataulphus (*q.v.*) the successor of Alaric, and the husband of Placidia, daughter of the emperor Theodosius, whom he had married against the wish of her brother Honorius, entered Spain in 412, as the ally of the empire. He was murdered in 415, but after the speedily ensuing murder of his murderer and successor Sigeric, Wallia (415–419), who was elected to the kingdom, continued his work. He destroyed the Alans, and drove the Vandals and Suebi into the north-west. Then he handed Spain back to the imperial officials, that is to say, to weakness and corruption, and marched with all his people into the Second Aquitaine, the south-west of modern France, which had been assigned to them by Honorius as a home and a reward. From this date till the very end of the reign of Amalaric (511–531), the seat of the Visigothic kings was at Bordeaux, or Toulouse or Narbonne, and their main interests were in Gaul. They continued to intervene in Spain and to extend their influence over it. But for an interval of more than twenty-five years they stood apart. Southern Spain was overrun and plundered by the Vandals before their departure for Africa. In 456 Theodoric II. (453–466) entered Spain as ally of Avitus, whom he had himself raised to the empire in Gaul. He defeated the Roman senators of the Tarraconensis and the Suebi, putting their king to death, and advanced as far as Mérida. But he was recalled to Gaul, and his return was accompanied by outrages against the Roman cities. Majorian (457–461), the last capable emperor of the West, proposed to make Spain the basis of his attack on the Vandals at Carthage till his fleet was destroyed by them in the harbour of Carthagena. The fratricidal murderer and successor of Theodoric, Euric (466–485) followed his brother's policy in Spain. With the extinction of the Western Empire (476 or 479) the kings of the Visigoths became more and more the representatives of authority, which they exercised on Roman lines, and with an implied or formal deference to the distant emperor at Constantinople. But the continued existence of the obscure Suevic kingdom in the north-west, the effective independence of several districts, and the rule of others by the Roman senators, proves that the regions actually under Visigothic rule were not extensive. After the defeat and death of Alaric II. (485–507) at Vouillé the shattered Visigoth power was preserved from destruction at the hands of the Frankish king Clovis (*q.v.*) by Theodoric, the Gothic king of Italy. But on his death the advance of the Franks began again. Amalarie (507–531) fled from Narbonne, to meet the usual violent end of a Visigothic king at Barcelona.

Character of Visigothic Kingdom.

The line of the Visigothic kings of Spain begins, strictly speaking, with his successor Theudis (531–548), an Ostrogoth appointed by Theodoric to act as guardian of Amalaric. He had acquired great possessions in the valley of the Ebro by marriage with a Roman lady. It was a government, and not a people, which was established in Spain with Theudis. The Visigoths had been much Romanized during their establishment in Gaul, and we hear of no exodus as having accompanied Amalaric. The example of Theudis is enough to show that the law of the Theodosian code which forbade the marriage of Romans and barbarians was not regarded by the Goths. It remained indeed unrepealed, as many laws have done since, long after it had become a mere dead letter. The government which came with Theudis, and fell to ruin with Roderic, may he described as having been at once Roman and bad. In so far as it was affected by the Visigoths it was influenced for the worse. Their monarchy was elective. Until the death of Amalaric the choice was confined to one family, but he was the last of his line. The kings tried to make the crown hereditary, and the nobles, Visigothic *seniores*, and Roman *senatores* seized every opportunity to keep it elective. Spain presented a forecast of the anarchy of Poland. Of the twenty-three kings between Theudis and Roderic five were certainly murdered, one was deposed, and three were tonsured by tricks or open force. Of the others some were passing phantoms, and the records of the later times of the kingdom are so obscure that we cannot be sure of knowing the names of all who perished by violence.

The administration which these kings of unstable authority had to direct was essentially the Roman system. The great owners, whether nominally Visigoth or nominally Roman—*seniores* or *senatores*—continued to enjoy all the privileges and exemptions of the *ordo senatorius* in the last days of the empire. They lived surrounded by multitudes of semi-servile *coloni*, or farmers, bound to the soil, of actual slaves, and of *buccelarei*, who were free swordsmen to whom they gave rations (*buccelatum*, soldiers' bread, or *buccella*, a portion). The *curiales* remained as before the victims of the fisc. How far the fact that Theudis and the four next sovereigns were Arians affected their government is not very clear. It prevented them from enjoying the active support of the Catholic clergy. But it is very doubtful whether Christianity had spread much beyond the cities. We hear of the conversion of pagans down to the last days of the Visigothic kingdom. The spread of Mahommedanism was so rapid in the first years after the conquest that it is impossible to believe that the country had been thoroughly christianized.

The Visigothic Kings.

Theudis, who made his headquarters at Seville, endeavoured to complete his mastery of the diocese of Spain by occupying Mauritania Tingitana, but he was defeated by the imperial officers at Ceuta. He was in due course murdered at Seville by Theudigisel (548–549) who was himself promptly slain. The reigns of his two successors, Agila (549–554) and Athanagild (554–567), coincided with the reign of Justinian and the temporary revival of the Eastern Empire. Athanagild called on the imperial officers to help him against Agila, and paid for their assistance by the surrender of the province of Baetica. On his death there was an obscure interregnum of five months, which ended by the election of Liuva (567–572), the governor of Narbonne, the surviving remnant of the Visigoth power to the north of the Pyrenees. Liuva did not come to Spain, but associated his brother Leovigild (567–586) with him. The reigns of Leovigild and of his son Reccared are the greatest in the list of the Visigoth kingdom in

Spain. The father was manifestly a man of great energy who cowed his unruly nobles by murder, forced the Orospedans to recognize his superiority, swept away the Suevic kingdom which had lingered in the north-west, and checked the raids of the Basques. To secure the succession in his family he associated his sons Hermenegild and Reccared with himself. He was the first Visigothic king who wore the crown, and it would appear that he threw off all pretence of allegiance to the empire. The series of the Visigothic gold coins begins with him, and it is to be noted that while the earliest are struck in the name of the emperor Justinian, the imperial superscription disappears in the later. Leovigild drove the imperial officers from Seville and Cordova, though they still retained control of the coast. His son Hermenegild, to whom he entrusted the government of Baetica, was married to a Frankish princess. Intermarriages had not been uncommon between Frank and Visigoth, but they had rarely led to any other result than to subject the Arian ladies who were sent from Spain, or the Catholic ladies who came from France, to blows and murder by their husbands and their husbands' families. Ingunda the Frankish wife of Hermenegild, with the help of Leandro, archbishop of Seville, the brother and predecessor of the more famous Isidore (*q.v.*), persuaded her husband to renounce Arianism. He revolted against his father, was reduced to submission and executed in prison.

The reign of Reccared (586–601) is famous in Spanish history for the establishment of Catholicism as the religion of the state. Reccared must have seen from the example of the Franks that the support of the Church was a great element of strength for the Crown. He made the change at the Third Council of Toledo. If Reccared hoped to secure the perpetuance of his dynasty he was mistaken. His son Liuva the second (601–603) was murdered by an Arian reaction headed by Witteric (603–610). The Catholics regained power by his overthrow, but they could not give stability to the state. A succession of obscure "priests' kings," who are but names, followed: Gunthemar (610–612), Sisebut (612–620), Reccared II. (620–621), Swintella, associated with his son Reccimer (621–631), Sisinand (631–636), Chintila (636–640), Tulga (640–641), Chindaswinth (641–652), Recceswinth (649–672). The growing weakness of the Merovingians saved them from serious attack, though not from occasional invasion on the north. The prostration of the empire in the East by Avar and Persian invasions enabled them to drive the imperial officers from the coast towns. But the kingdom was growing internally weaker. The nobles were strong enough to prevent the monarchy from becoming hereditary. The Church seemed to exert great power, but it had itself become barbarized by contact with kings and nobles. Violent persecutions of heretics and of the numerous Jews brought in new elements of discord. Wamba (672–680) is credited with an attempt to reform the state, but he was tonsured while unconscious from illness or poison, and disappeared into a religious house. His successors again are but names, Euric (680–687) and Egica (687–701). Witiza (697–710) has more substance. He was in aftertimes denounced as a monster of vice, whose sins accounted for the Mahommedan conquest. Contemporaries speak of him with respect, and he appears to have been a well-meaning man who endeavoured to check the corruption of the clergy and the persecution of the Jews, and who resisted the dictation of the pope. His reign ended in turmoil, and perhaps by murder. With Roderic, whose "tumultuous" election was the work of Witiza's enemies, the line of the Visigoth kings is considered to have ended.

Organization of the Visigothic Kingdom.

The Visigoth kingdom presents an appearance of coherence which was very far from corresponding to the reality. At the head was the king, surrounded by his household of *leudes*, and aided by the palatines, great officers of state imitated from the imperial model. At the head of the provinces, eight in number, were dukes, and the cities were governed by counts. Both were, at least in theory, officers named by the king and removable by him. The king was advised by councils, made up by a combination of a senate of the great men, and of the ecclesiastical councils which had met under the Roman rule and that of the tolerant Arian kings. The formation of the council was not complete until the establishment of Catholicism as the state religion. But from the reign of Reccared till the Arab invasion they met sixteen times in all, generally at Toledo in the church of Santa Leocadia. Purely ecclesiastical matters were first discussed by the clergy alone. Then the great men, Visigoth and Roman, joined with the clergy, and the affairs of the kingdom were debated. The *Leges Wisigothorum* were elaborated in these councils (see GERMANIC LAW). But there was more show than reality in this parade of government by free discussion and by law. There was no effective administration to enforce the law.

Moslem Invasion, 711.

The Mahommedan Conquest.—How utterly weak it was can be seen from the fact that it was shattered by the feeble Moslem invasion of 711. The danger from Africa had been patent for half a century. During the reign of Witiza the Moslem masters of northern Africa had pressed the town of Ceuta, the last remnant of the Byzantine possessions, very closely, and it had been relieved by supplies from Spain. Only the want of ships had prevented the Mahommedans from mastering the town, and crossing the straits, and now this deficiency was supplied by the Christians themselves. It seems to be certain that Julian, the imperial count or governor of Ceuta, acting in concert with the family and faction of Witiza, who sought his help against Roderic, provided vessels to transport the Berber Tarik (Tāriq) across the straits. Tarik, the general of the caliph's governor in northern Africa, Mūsā b. Nosair, was invited as an ally by the conspirators, who hoped to make use of him and then send him back. He came with a small force, but with the certainty of finding allies, and on being joined by another detachment of Berbers marched inland. On the 19th of July 711 he met Roderic near the Lago de la Janda between Medina Sidonia and Vejer de la Frontera. He had perhaps already been joined by Spanish allies. It is at least certain that in the battle the enemies of Roderic passed over to the invader. The Visigoth king was routed and disappears from authentic history. There is some probability that he did not perish in the battle, but escaped to fall two years later, at Seguyjuela near Salamanca, in action with Merwan the son of Mūsā. A single blow delivered as much by Christian as by Moslem hands, sufficed to cut the bond which seemed to hold the kingdom together, and to scatter its fragments all over the soil of the Peninsula.

The Mahommedan Conquest.

Through these fragments Tarik marched without a single check of importance. Before the end of 711 he had advanced as far north as Alcalá. Córdova fell to a detachment of his army. In 712 Mūsā joined his lieutenant, and the conquest of the south was completed. Mérida was the only town which offered an honourable resistance. During 713 and 714 the north was subdued to the foot of the mountains, and when Mūsā and Tarik were recalled to Damascus by the caliph the progress of the Moslems was not delayed. In 718 they crossed the Pyrenees, and continued their invasions of Gaul till they met the solid power of the Austrasian Franks at Poitiers 732 (see CHARLES MARTEL and CALIPHATE, B. §§ 6, 10). The rush of the Mahommedan flood sent terror all over Europe, but the little opposition it encountered south of the Pyrenees is to be easily explained, and the victory, though genuine, was more specious than substantial. That the lieutenants of the caliph at Damascus should take the place of the Visigoth kings, their dukes and counts seemed to many no loss and to a still greater number a gain. The great landowners, to whom patriotism was unknown and whose religious faith was tepid, were as ready to pay tribute to the caliph as to render service to one of their own body who had become king by violence or intrigue. On the part of the Arabs, who, though a small minority of the invaders, were the ruling element, there was a marked absence of proselytizing zeal. They treated the occupation of Spain as a financial speculation more than as a war for the faith.

Character of Arab Rule.

The Arab, though he produced Mahommedanism, was the least fanatical of the followers of the Prophet, and was not only willing but desirous to leave to all men who would pay tribute the free exercise of their religion. He cynically avowed a greater liking for the poll tax paid by the Christian than for his conversion. The Spanish Roman and the Visigoth, so-called, of that epoch of poorness of spirit, accustomed as he was to compound with one master after another, saw nothing dishonourable in making such an arrangement. That it was made is matter of record. In Murcia the duke whom the Arabs knew as Tadmir became a tributary prince, and his family retained the principality for generations. He no doubt contrived to induce the Arabs to recognize him as the owner of what had been public domain, and made an excellent bargain. The family of Witiza did obtain possession of an immense stretch of the land of the state in Andalusia on condition of paying tribute. One of them, by name Ardabast, was deprived of his holding at a later date on the ground that he held more land than could be safely left in the hands of a Christian. Everywhere landowners made the bargain, and the monasteries and the cities followed their example. Nor was submission and payment of tribute all that they were prepared to give. Many professed themselves converts to Mahommedanism. In the north one great Visigoth family not only accepted Islam, but founded a dynasty, with its capital at Saragossa, which played a stirring part in the 8th and 9th centuries, the Beni-Casi, or Beni-Lope. To the mass of the population the conquest was, for the present, a pure gain. The Jews, escaped from brutal persecution, were the eager allies of the Arabs. As the conquerors swept away the Roman fiscal system, which the Visigoths had retained, and replaced it by a poll tax (which was not levied on old men, women, children, cripples or the very poor) and a land tax, the gain to the downtrodden serfs of the fisc was immense. They acquired personal freedom. Add to this that a slave who professed Islam could secure his freedom, at least from slavery to a Christian master, that Arianism had not been quite rooted out, that the country districts were still largely pagan, and it will not appear wonderful that within a generation Mahommedan Spain was full of renegades who formed in all probability a majority of its population and a most important social and political element. The Arabs at first were content to take a fifth of the land to constitute the public domain, or *khoms*, out of which fiefs held on military tenure were provided for the chiefs of the conquering army.

If this moderate policy had been or could have been steadily pursued, the invaders would in all probability have founded a lasting state. But it could not be pursued, since it required for its application a consistency, and a power to act on a definite political principle, of which the Mahommedan conquerors were absolutely destitute. Nor had Spain been conquered by a single race. The invaders were a coalition of Arabs, Syrians and Berbers. The Arab was incurably anarchical, and was a noble who had no political idea except the tribal one. That their personal dignity must be asserted and recognized was the first article in the creed of these descendants of the heroes of the desert. They looked down on the Syrian, they thought the Berber a lout and a plebeian, they scorned the renegade, and called him a slave and son of a slave. They fought out the old tribal rivalries of Arabia on the banks of the Guadalquivir and on the Vega of Granada: They planted the Berber down on the bleak, ill-watered, and wind-swept central plateau. He revolted, and they strove to subdue him by the sword. He deserted his poor share of the conquered land, and in many cases returned to Africa. The conflict for the caliphate (*q.v.*) between Omayyad and Abbasid removed all shadow of control by the head of the Mahommedan world, and Spain was given up to mere anarchy. The treaties made with the Christians were soon violated, and it seemed as if Islam would destroy itself. From that fate it was preserved by the arrival in Spain of Abdurrahman (Abdarrahman b. Moawiya) the Omayyad (758), one of the few princes of his house who escaped massacre at the hands of the Abbasides. With the help of his clansmen among the Arabs, and to a large extent of the renegades who counted as his clients, by craft, by the sword, by keeping down the fanatical Berber element, and by forming a mercenary army of African negroes, and after thirty years of blood and battle, Abdurrahman founded the independent amirate, which in the 10th century became the caliphate of Cordova. It was an Oriental monarchy like another, strong when the amir was a strong man, weak when he was not, but exceptionally rich in able men. Its rulers had to fight the Arab nobles as much as the Christians, and the real basis of their power was their slave army of negroes, or of Christian slaves, largely Slavonians sold by their German captors to the Jew slave traders of Verdun, and by them brought to Spain. These janissaries at first gave them victory, and then destroyed them.

Christian States of the North.

Such a kingdom as this needed only attack from a more solidly organized power to be shattered. The Christian enemies of the Mahommedans were for long weak and no less anarchical than themselves, but they were never altogether wanting, and they had, what the Arab and Berber had not, a tradition of law and a capacity for forming an organized polity and a state. They are to be sought for along the line of the mountains of the north. In the centre were the Basques, dwelling on both sides of the Pyrenees, who kept against the Mahommedan the independence they had vindicated against the Visigoth. On the east of the Basques, along the line of the Pyrenees, were others of kindred blood, who also kept a rude freedom on the slopes and in the valleys of the mountains. The Arab passed through them, going and returning to and from Gaul, but he never fully conquered them. The names of their leaders Garci Jeminez and Iñigo Arista are altogether legendary. But here were the roots of the kingdom of Navarre, of Sobrarbe and Aragon. In the earliest times their most pressing foe was not the Arab or Berber so much as the Carolingian. It was at their hands that Charlemagne (*q.v*), while returning from his expedition to Saragossa, suffered that disaster to his rearguard at Roncesvalles which is more famous in poetry than important in history. With the aid of the Spanish Moslem Beni-Casi the Basques drove off the counts and wardens of the marches of the Carolingians. On the eastern extremity of the Pyrenees the Franks found no native free population. Here, mainly under the leadership of Louis the Pious, they formed the Marca Hispanica, where Frankish counts and wardens of the marches gradually gained ground. By the reign of Charles the Fat a principality had been founded. Wilfred the Hairy—the *Comes Vellosus*, so called because his countship was poor and covered with scrub wood, and not because the palms of his hands were covered with hair as the legend has it—became the founder of the counts of Barcelona.

The greatest destiny was preserved for the Christian remnant which stood out to the west of the Basques, in the mountains of Asturias. Pelayo, whom they chose for king, and his victory of Covadonga, are well nigh as legendary, and are quite as obscure as Garci Jimenes and Iñigo Arista. Yet it is certain that in this region were planted the seeds of the kingdom of Castile and Leon, the dominant power of the Spain of the future. The total silence of the contemporary chronicle, called by the name of Isidore of Beja, shows that in the south of Spain, where the writer lived, nothing was known of the resistance made in the north. The next Christian authorities belong to the latter part of the 9th century. It is therefore with the warning that the dates can only be given as probably correct that the three first Christian kings can be said to have reigned from 718 to 757. Pelayo (718–737), his brother Favila (737–739)—of whom we only know that he is said to have been killed by a bear while hunting—and Alphonso I., the Catholic (739–757), stand as little more than names. While the invasion of Gaul was still going on Manuza, the chief of the Berbers settled in north-western Spain, had revolted against the caliph's lieutenants. In 740 came the great general revolt of the Berbers. In 750 plague, following on drought and famine, swept away thousands of conquered and conquerors alike. Amid the general desolation Alphonso I. duke of Cantabria and son-in-law of Pelayo, constituted the kingdom which the Arabs called Gallicia. It answered closely to the old Roman province of the same name—extending from the Bay of Biscay to the line of the Duero, from the ocean to the foot of the mountains of Navarre. Internally it was divided into two belts. Along the shores of the bay, and in the valleys of the mountains to the north and west it was inhabited;

Kingdom of Gallicia.

but a great belt of desolation separated it from the regions in which the Moslem were fighting out their own quarrels. Alphonso swept all through that region, already more than half depopulated, slaying the lingering remnants of the Berbers, and carrying hack the surviving Christians to the north. Behind that shield of waste the Christian kingdom developed; from the death of Alphonso I. to the reign of Ramiro II. (931–950) it was subject to no serious attack, though raids on the frontier never ceased. Norse pirates appeared on the coast in the 9th century, but made no permanent settlements. As the population grew, it pushed down to the plain of Leon and Castile. The advance is marked by the removals of the capital forward from Cangas de Oña to Oviedo, from Oviedo to Leon, and by the settlement of adventurous frontier men in the ancient Bardulia, which from their "peels," and towers of strength, gained the name of Castilla—the castles. Burgos became its centre. The Montaña (hill country) of Burgos, and in particular the district called the Alfoz of Lara, was the cradle of the heroes of the Castilian share in the reconquest—the count Porcellos, and the judge of the people, Lain Calvo, the infantes of Lara, the bastard Mudarra, and Ruy Diaz of Bivar, in whose lives legend and history are mingled beyond disentanglement, and of whom some are pure figures of romance. By a process which was going on elsewhere in Europe the frontier settled into a new political organism. As the Marca Hispanica on the east became the county of Barcelona, so the chiefs of Bardulia became the counts of Castile, then the count of Castile, the rival of the king at Leon, and in time the king of Castile, and head of Christian Spain.

There is much in the internal history of that kingdom which stands apart from the general development of western Europe, from which it was shut out. In all the long period from Pelayo to Ramiro II. only one event occurred which had much tendency to bring the Christians of the north-west into close relations with their neighbours of the same faith north of the Pyrenees. This was the discovery, or, in strict ecclesiastical language, the "invention" of the body of St James the Apostle in the reign of Alphonso II. the Chaste (789–842). The shrine at Santiago in Gallicia was accepted in an age when evidence and criticism were words of no meaning, and it attracted pilgrims, who brought trade. But, apart from this opening for foreign influence, the Christians were left to develop their order untouched by alien examples, and they developed from the Visigoth monarchy. The men who raised Pelayo on the shield believed themselves to be electing a successor to Roderic, and indeed they were. They continued for a time to call themselves Goths, and to claim Gothic descent, which had become for them very much what descent from the companions of the conqueror was to Englishmen of the 14th or 15th centuries and later—another name for nobility of blood. There was the same king possessing theoretically almost absolute power, both administrative and legislative; the same nobles who limited his effective power by rebellion, their constant effort to keep the crown elective, and his no less steady, and by the 10th century victorious, effort to make it hereditary; the same distinction between the few free, who are also the rich owners of land, and the many serfs, who are partial bondsmen, or the slaves pure and simple. But the fact that every arm was needed for the raids on the frontier, and to provide settlers who should also be garrison for the regained lands, worked for freedom. The serf, who was also a soldier, revolted against bondage. The chief who had to "people" a new and exposed township had to tempt men by freedom and secure rights to follow his banner. The influences which by the 13th century had abolished serfdom in western Spain were all at work before the reign of Ramiro II. In spite of revolts and of fratricidal struggles a state was formed. To the east of it, the Navarrese, having rid themselves of the Carolingian counts and marchers, had made a kingdom in their mountains, and beyond them the little free territories of the central Pyrenees were advancing, in subordination to the Navarrese king at Pamplona. The Arab called them the Christians of Al Frank, and distinguished them from the Gallicians.

The 10th century and the first years of the 11th saw a great set-back of the Christian revival. Dissensions among themselves coincided with an energetic rally of the Moslem power. From the foundation of the amirate by Abdurrahman I. (758–790) to the beginning of the reign of Abdurrahman III. (912–961) Mahommedan Spain had shared the usual fortunes of an Oriental monarchy. A strong amir, such as Abdurrahman I. or his grandson Hakam I. (796–822), could enforce obedience by arms, or by murder, but it was the rule of the most pugnacious and the hardest hitter. Even with him it was often only apparent. On the upper frontier, which is now Aragon, the "Visigoth" Beni-Casi ruled, doing homage and paying tribute intermittently, supported by a loyal population of native Mahommedans, whose Christian or nominally Christian fathers had been their followers before the conquest. The "Moors," so called, who afterwards filled the kingdom of Aragon were of native blood. Toledo, relying on the immense military strength of its position, was more often in rebellion than in subordination. The massacre which Hakam I. effected by a lavish use of fraud cowed it only for a time. Abdurrahman III. found it independent again when he came to the throne, and had to besiege it for two years before it yielded. The renegades grew in numbers, and in faith. Under the influence of orthodox Berber teachers their fanaticism was turned against the amir himself. Hakam, a winebibber much suspected of heterodoxy, had to expel thousands from his capital. Part went to people the town of Fez, newly founded in the Morocco, by the Idrisites. Part wandered eastward to found a Mahommedan state in Crete. Under the stimulus of Berber fanaticism the toleration first shown to the Christians was turned to persecution. A counter fanaticism was aroused in them, and for years the "Martyrs of Cordoba" continued to force the often reluctant cadis to behead them, by blaspheming the Prophet. The relations of the amir to the Christian bishops were very much those of the Ottoman sultan to the Greek patriarch. There were Spaniards who, like the Greeks of the Phanar, were the servile instruments of their Moslem master. Under Abdurrahman II. (822–852), who spent his life listening to a favourite and highly accomplished Persian tenor and in the company of dancing girls, and under Mahommed I. (852–886), the niggardly Mondhir (886–888), whose time was short, and Abdalla (888–912), who was feeble, the amirate was torn to fragments.

The Mahommedan Amirate. Period of Anarchy.

From this state of anarchy the amirate was saved by Abdurrahman III. (912–961), the Akbar of his race. He came to the throne when half a century of war and murder had produced exhaustion. The country was swarming with brigands, and the communications were so dangerous that seven years had been known to pass during which no caravan travelled from Cordova to Saragossa. There was a disposition on all hands, save among the irreconcilable Christians of the Sierra de Ronda, to accept peace under a capable master. The Arabs were beaten down, and the renegades had gained most of what they fought for when the aristocracy was cowed. Abdurrahman III., an Oriental ruler of the great stamp, industrious, resolute, capable of justice, magnificent, and free handed without profusion, was eminently qualified to give all that his people wanted. The splendour of his reign is a commonplace. He restored order even in the Ronda, and then he took the field against the Christians. He obeyed the rule which has called upon all the intelligent governors of Spain to make sure of the African coast by occupying it. He saw the Christian princes of the north become his vassals and submit to his judgment in their quarrels. But within a period not so long as his own life his dynasty was extinct and his kingdom in fragments.

Revival under Abdurrahman III.

Hakam II. (961–976), Abdurrahman's son, ascended the throne in mature years, and continued his father's policy. A lover of books, he gave protection to writers and thinkers who were not strictly orthodox. From his Christian neighbours he had nothing to fear. The anarchy which broke out in the north-west, the kingdom now called Leon, on the death of Ramiro II.—whose sons fought among themselves—and the endless conflicts between Leon and Castile, rendered the only formidable Christian kingdom powerless. Even on Hakam's death the power of the caliphate was exercised for some thirty years with great vigour. In his old age, one of his wives Sobh (the Daybreak), a Basque, bore him the first son born in his harem. To this son Hishām II. (976– ?) he left the crown. The rule went to the sultana, and her trusted agent Ibn Abī 'Amir Mahommed ben Abdallah—an Arab of noble descent, who in his early life was a scribe, and who rose by making himself useful first to the ministers and to the favourite wife. By them he was promoted, and in time he brought their ruin. By her he was made *hajib*—lord chamberlain, prime minister, great domestic, *alter ego*, in short, of the puppet caliph—for Hishām II. in all his long life was nothing else—and in due time he reduced the sultana to insignificance. The administration of Mahommed ben Abdallah, who took the royal name al-Mansur Billah ("the victorious through God") and is generally known as Mansur (*q.v.*), is also counted among the glories of the caliphate of Cordova. It was the rule of a strong man who made, and kept under his own control, a janissary army of slaves from all nations, Christian mercenaries from the north, Berbers and negroes from Africa. With that host he made fifty invasions into the Christian territory. A more statesmanlike conqueror leading a people capable of real civilization would have made five, and his work would have lasted. Mansur made raids, and left his enemies in a position to regain all they had lost. It mattered little that he desolated the shrine of St James at Compostella, the monastery of Cardeña in Castile, took Leon, Pamplona and Barcelona, if at the end he left the roots of the Christian states firm in the soil, and to his son and successor as *hajib* only a mercenary army without patriotism or loyalty. In later times Christian ecclesiastical writers, finding it difficult to justify the unbroken prosperity of the wicked to an age which believed in the judgment of God and trial by combat, invented a final defeat for Mansur at Calatañaxor. He died in 1002 undefeated, but racked by anxiety for the permanence of the prosperity of his house. His son Mozaffar, kept the authority as *hajib*, always in the name of Hishām II., who was hidden away in a second palace suburb of Cordova, Zahira. But Mozaffar lasted for a short time, and then died, poisoned, as it was said, by his brother Abdurrahman, called Sanchol, the son of Mansur by one of the Christian ladies whom he extorted for his harem from the fears of the Christian princes. Abdurrahman Sanchol was vain and feather-headed. He extorted from the feeble caliph the title of successor, thereby deeply offending the princes of the Omayyad house and the populace of Cordova. He lost his hold on his slaves and mercenaries, whose chiefs had begun to think it would be more to their interest to divide the country among themselves. A palace revolution, headed by Mahommed, of the Omayyad family, who called himself Al Mahdi Billah (guided by God), and a street riot, upset the power of the *hajib* at Cordova while he was absent on a raid against Castile. His soldiers deserted him, and he was speedily slaughtered. Then in the twinkling of an eye the whole edifice went into ruin. The end of Hishām II. is unknown, and the other princes perished in a frantic scramble for the throne in which they were the puppets of military adventurers. A score of shifting principalities, each ready to help the Christians to destroy the others, took the place of the caliphate.

Administration of Mansur.

Abdurrahman Sanchol.

End of the Empire of Abdurrahman III.

The fundamental difference between the Moslem, who know only the despot and the Koran, and a Christian people who have the Church, a body of law and a Latin speech, was well seen in the contrast between the end of the greatness of Mansur, and the end of the weakness of his Christian contemporaries. The first left no trace. The second attained, after much fratricidal strife, to the foundation of a kingdom and of institutions. The interval between the death of Ramiro II. in 950 and the establishment of the kingdom of Castile by Fernando I. in 1037 is on the surface as anarchical as the Mahommedan confusion of any time. The personages are not anywise heroic, even when like Alphonso V. (999–1027) they were loyal to their duty. Sancho the Fat, and Bermudo II. the Gouty, with their shameless feuds in the presence of the common enemy, and their appeals to the caliph, were miserable enough. But the emancipation of the serfs made progress. Charters began to be given to the towns, and a class of burghers, endowed with rights and armed to defend them, was formed; while the council of the magnates was beginning to develop into a Cortes. The council over which Alphonso V. of Leon and his wife Geloria (*i.e.* Elvira) presided in 1020, conferred the great model charter of Leon, and passed laws for the whole kingdom. The monarchy became thoroughly hereditary, and one main source of anarchy was closed. By the beginning of the 11th century the leading place among the Christian kings had been taken by Sancho El Mayor (the Great) of Navarre. He was married to a sister of Garcia, the last count of Castile. Garcia was murdered by the sons of Count Vela of Alava whom he had despoiled, and Sancho took possession of Castile, giving the government of it to his son Fernando, (Ferdinand I.), with the title of king, and taking the name of "king of the Spains" for himself. It was the beginning of attempts, which continued to be made till far into the 12th century, to obtain the unity of the Christians by setting up an emperor, or king of kings, to whom the lesser crowns should be subject. Fernando was married to a daughter of Alphonso V. of Leon. Her brother Bermudo, the last of his line, could not live in peace with the new king, and lost his life in the battle of Tamaron, in a war which he had himself provoked. Fernando now united all the north-west of Spain into the kingdom of Castile and Leon with Gallicia. Navarre was left by Sancho to another son, Garcia, while the small Christian states of the central Pyrenees, Aragon and Sobrarbe with the Ribagorza went to his other sons, Ramiro Sanchez and Gonzalo. Fernando, as the elder, called himself emperor, and asserted a general superiority over his brothers. That he took his position of king of kings seriously would seem to be proved by the fact that when his brother Garcia attacked him in 1054, and was defeated and slain at Atapuerca, he did not annex Navarre, but left his nephew, Garcia's son, on the throne as vassal. The Council of Coyanza, now Valencia de Don Juan (1050), at which he confirmed the charters of Alphonso V., is a leading date in the constitutional history of Spain. When he had united his kingdom, he took the field against the Mahommedans; and the period of the great reconquest began. So far the Christians had not gone much beyond the limits of the territory left to them at the end of the 8th century. They had only developed and organized within it. Under Fernando, they advanced to the banks of the Tagus in the south, and into Valencia on the south-east. They began to close round Toledo, the shield of Andalusia. The feeble Andalusian princes were terrified into paying tribute, and Fernando advanced to the very gates of Seville without finding an enemy to meet him in the field. His death in 1065 brought about a pause for a time. He left his three kingdoms to his three sons Sancho, Alphonso and Garcia. Alphonso, to whom Leon had fallen as his share, remained master after the murder of Sancho at Zamora, which he was endeavouring to take from his sister, and the imprisonment of Garcia of Gallicia. The reign of Alphonso VI., which lasted till 1109, is one of the fullest in the annals of Spain. He took up the work of his father, with less of the crusading spirit than was in Fernando, but with conspicuous ability. His marriage with Constance, daughter of Robert, duke of Burgundy, brought a powerful foreign influence into play in Castile. Constance favoured the monks of Cluny, and obtained her husband's favour for them. Under their leadership measures were taken to reform the Church, from which hitherto little had been expected save that it should be zealous and martial. The adoption of the Roman instead of the Gothic

French Influence.

ritual of Saint Isidore has been lamented, but it marked the assumption by Castile of a place in the community of the western European kingdoms. The Frenchmen, both monks and knights, who accompanied Constance brought to bear on Spain the ecclesiastical, architectural, literary and military influence of France, then the intellectual centre of Europe, as fully as it ever was exercised in later times. Castile ceased to be an isolated kingdom, and became an advance guard of Europe in not the least vital part of the crusades. Alphonso, who during his exile owed some good services to the Mahommedan king of Toledo, spared that city while his friend lived.

Alphonso overruns Mahommedan Spain.

But he carried the war forward elsewhere. He extorted tribute, and double and treble tribute from the princes of Andalusia. In 1082 he swept all through the valley of the Guadalquivir to Tarifa, where he rode his horse into the sea and claimed possession of the "last land in Spain." In 1084, his friend being dead, he made himself master of Toledo. The fall of the city resounded throughout Islam, and shocked the Mahommedan princes of Andalusia into gravity and a sense of their position. Their peoples began to look to Africa, where Yusuf ben Techufin was ruling the newly founded empire of the Almorâvides. The princes had cause to dread him; for Yusuf, the leader of a religious movement still in its first zeal, was known to have no friendly feeling for their religious indifference and elegant, dissipated habits. It was likely that, if he came as ally, he would remain as master.

Invasion of the Almorâvides.

But the case was excellently put by al-Motamid, amir of Seville, a brilliant cavalier, an accomplished Arab poet, and one of the most amiably spendthrift of princes. When the peril of appealing to Yusuf was put before him at durbar by his son, he acknowledged the danger, but added that he did not wish to be cursed throughout Islam as the cause of the loss of Spain and that, if choose he must, he thought it better to lead camels in Africa than to tend pigs in Castile. Yusuf came, and in 1086 inflicted a terrible defeat on Alphonso VI. at Zalaca near Badajoz. The immediate results of the stricken field were, however, but small. Yusuf was called back to Africa, and in his absence the Christians resumed the advance. When he returned he was chiefly employed in suppressing the Mahommedan princes. Alphonso was compelled to withdraw a garrison he had placed in Murcia, and Valencia was, by his decision, given up by the widow of the Cid (*q.v.*). But he kept his hold on Toledo, and though his last days were darkened by the death of his only son in the lost battle of Ucles (1108), he died in 1109 with the security that his work would last.

Decline of the Mahommedan Power under the Almorâvides.

The Almorâvides went round the fatal circle of Asiatic and African monarchy with exceptional rapidity. One generation of military efficiency and of comparative honesty in administration was followed by sloth and corruption as bad as that of the Arabs. To this the Almorâvides, who were Berbers and were largely mingled with pure negroes, added a dull bigotry and a hatred of thought and knowledge from which the Arab, anarchical and politically incapable as he was, was free. In Aragon the successors of Ramiro Sanchez had begun to press close on Saragossa when the Almorâvide invasion took place. The battle of Zalaca gave pause to the Aragonese, as it did for a short space to the Castilians. The interval of advance in the reconquest would have been shorter than it was but for the results of a most unfortunate attempt on the part of Alphonso VI. to unite the crowns of Aragon and Castile by the marriage of Alphonso I. (1104–1134) of Aragon with his daughter Urraca. Urraca (the name is a form of Maria) was dissolute and Alphonso was arbitrary.

Alphonso I. of Aragon, 1104–1134.

There was nothing in the manners of the 12th century to make a husband hesitate to beat his wife, and Urraca was beaten, and in the presence of witnesses. The marriage, too, was declared null by the pope, as the parties were within the prohibited degrees. Alphonso and Urraca came to open war, in which he claimed to be king of Castile by right of his marriage and his election by the nobles. The confusion was increased by the fact that Alphonso, Urraca's son by her first marriage with Raymond of Burgundy, was recognized as king in Gallicia, was bred up there by the able bishop Diego Gelmirez, and took an active part in the feuds of his mother and step-father. The death of Urraca in 1126 allowed her son to reunite the dominions of his grandfather. In the meantime his quarrels with Urraca had not deterred Alphonso, who is surnamed the Battler in Aragonese history, from taking Saragossa in 1118, and from defeating the Almorâvides at the decisive battle of Cutanda in 1120. In 1125 he carried out a great raid through Mahommedan Spain, camping in its midst for months, and returning with many thousands of the Christian *rayahs*, who, under the name of Mozárabes, had hitherto continued to live under Moslem rule. They now fled from the bigotry and negro brutality of the Almorâvides. The failure of Alphonso's attempt to take Braga in 1134 was speedily followed by his death. He left his kingdom by will to the Knights of the Temple and the Hospital, but the barons of Aragon paid no attention to his wish, and drew his brother Ramiro, a monk, from his cell to continue the royal line. Ramiro, having been first ex-claustrated by the pope, married Agnes of Aquitaine, and on the birth of his daughter Petronilla affianced her to Ramon Berenguer (Raymond Berenger), count of Barcelona, and then retired to his cell at Narbonne.[1]

Union of Aragon and Catalonia.

This marriage united Aragon and Catalonia for ever, and marks a great step forward in the constitution of a national unity in Spain.

Kingdom of Navarre.

Navarre, indeed, which had been united with Aragon since the fratricidal murder of its king Sancho in 1076, preferred to remain independent under a new ruler of its choice. It was henceforth a small state lying across the Pyrenees, dependent on France, and doomed inevitably to be partitioned between its great neighbours to north and south.

Alphonso VII., "Emperor in Spain."

Alphonso VII., the son of Urraca, was, during the twenty years between his mother's death and his own in 1157, the dominating sovereign of Spain. In 1135 he was crowned at Leon, in the presence of the new king of Navarre, of the counts of Barcelona and Toulouse, and of other princes, Christian and Mahommedan, "Emperor in Spain, and king of the men of the two religions." In his character of emperor and king of the men of the two religions Alphonso VII. seems to have aimed not at expelling, but at reducing the Moors to subjection as vassal communities. He took Cordova and conquered as far as Almeria, but left vassal Moslem princes in possession.

End of the "Empire."

His death was followed by another and, happily, a last division of Castile and Leon. Sancho, his eldest son, took the first and Fernando the second. The dream of the empire was speedily dissipated by the death of Sancho of Castile a year after his father; Portugal had already become a semi-independent state.

Alfonso VIII. of Castile, 1158–1214.

The complicated story of the Christian kingdoms of Spain during the next two generations can be best made intelligible by taking the king of Castile as the centre of the turmoil. His boyhood was filled by all the miseries which rarely failed to descend in the middle ages on the people whose king was a child. Alphonso VIII. married Leonora, daughter of Henry II. of England, who, as duke of Aquitaine, by right of his marriage with the duchess Eleanor, had a strong direct interest in Spanish politics. Castile, by its geographical position as the centre of Spain from Cantabria to the Sierra Morena, was the forefront of the struggle with the Moors.

War with the Almohâdes.

In Andalusia the downfall of the Almorâvides had opened the way to the Almohâdes, or followers of the Mahdi, an even more bigoted religious sect than the other. Alphonso had conquered Cuenca, in the hill country between Castile and Valencia, in 1177, with the help of the king of Aragon, also an Alphonso, the son of Petronilla and of Ramon Berenguer of Barcelona. With eminent good sense he rewarded his ally by resigning all claim to feudal superiority over Aragon.

[1] Raymond du Puy, grand master of the Hospitallers, came to terms with Count Raymond in the matter of the bequest. (See SAINT JOHN OF JERUSALEM, KNIGHTS OF.)

At a later period the two kingdoms defined their respective spheres of influence by a treaty.

Recognition of the independence of Aragon.

Aragon was left free to conquer the Balearic Islands and Valencia, while Murcia and Ardalusia were to fall to Castile. The Almohâdes took the field against Alphonso in force, and as his fellow Christian sovereigns failed him in the hour of need, he was defeated at Alarcos. But this wave of the ebbing Moslem tide had less force than the Almorâvide, and fell back both sooner and farther than its predecessor.

Organization of the Kingdom. The Military Orders.

Alphonso had leisure to punish his brother kings for deserting him, and to look to the organization of his kingdom. It was a great epoch of the granting of charters, and of the advance of the towns. To this age also belongs the formation of the great monastic military orders of Calatrava, Santiago and Alcántara. They supplied the Crown with a strong force of well-disciplined and well-appointed cavalry. To tighten the bond with Leon, Alphonso of Castile married his daughter Berengaria to its king Alphonso (1188–1230), the son of his uncle Fernando. The marriage was dissolved by the pope as being within the prohibited degrees, but the son born of it was recognized as legitimate. Berengaria, a woman of very noble character and eminent ability, deserved a better husband than her cousin of Leon, who was nicknamed El Baboso—the Slobberer—and who appears to have been epileptic. In 1212 the king of Castile reaped the reward of long years of patience. The Almohâdes threatened an invasion in force, and he organized a crusade against them. Aragon was represented by its king Peter II., Navarre by its king Sancho, and Portugal by a strong contingent of Templars and other knights.

Overthrow of the Almohâdes.

At the Navas de Tolosa, just south of the Sierra Morena, the Almohâdes received the final overthrow which laid Mahommedan Spain at the feet of the Christians. Alphonso died in 1214. His son Enrique (Henry) was killed by the fall of a tile three years later; and Berengaria, to whom the crown came, sent to Leon for her son Fernando, and abdicated in his favour.

Ferdinand III., 1217–1252.

Fernando (Ferdinand III.) who was in all ways worthy of his mother, took up the crusading duty of a king of Castile, and continued the advance into Andalusia. The Almohádes were in swifter decline than the Almorâvides. One of them, al-Mamun, even sought Fernando's help to regain his throne in Morocco, and ceded a suburb of the city to his Christian allies. In 1230 the death of Alphonso of Leon opened the way to a final union of the crowns. The "Baboso" had, indeed, left his kingdom by will to his daughters by Teresa of Portugal, but Fernando was saved from the necessity of enforcing his rights by his mother. She persuaded Teresa and the infantas to resign their claims in return for pensions and lordships.

Final Union of Castile and Leon.

Castile and Leon were united, never to be divided again. The work of the reconquest was now completed with swift steps. In 1236 Cordova was conquered, and Seville fell in 1248 with the help of a fleet from the Basque coast and of the Moorish king of Granada, who was Fernando's vassal, paying tribute and attending Cortes when summoned. Fernando died in May 1252. It will avoid repetition to note here that the Aragonese share of the reconquest was completed by James the Conqueror (1213–1276), the son of that king Peter who fought in the Navas de Tolosa. He conquered the Balearic Islands in 1229 and Valencia in 1238. In 1265 he entered Murcia, which, however, he agreed to occupy in the name of Castile.

Reconquest of Spain, except Granada.

Mahommedan Spain was reduced to Granada and a line of ports round to Cadiz. The Christian population had disappeared in Granada and Moslem refugees had peopled it closely. Its king was a vassal, and of itself it was no longer a danger.

Spain after the Reconquest.

The close of the period of the great reconquest, five centuries of struggle, left Spain divided between two states of different character. On the west of the Iberian range and south of the Guadarrama was the kingdom called, for short, Castile and Leon. In fact its sovereign was also king of Gallicia, Asturias, Estremadura, Jaen, Cordova and Seville. This multiplicity of titles was more than a mere formula of the royal chancery. It was the official recognition of a substantial political fact—namely, that the kingdom of Castile and Leon had been made up by the agglutination of separate political entities.

Castile and Leon.

The real bond between them lay in the common crown, the common creed. They were one only as subjects of the same lords and members of the same Church. But their territorial patriotism was local. The peoples were not Spaniards, save as a general term, but Gallicians, Asturians, Castilians, Andalusians. The great foreign question for them was the possibility, and from time to time the imminence, of renewed invasion from Africa. That peril did not cease till the defeat of the last formidable African invader at the battle of the Rio Salado in 1340. It is characteristic of the loose construction of the kingdom that the Cortes of Leon and of Castile continued, after the final union, to meet apart on some occasions until 1301.

Aragon.

On the eastern slope of the Iberian hills and the great central table-land was the kingdom called, again for short, Aragon. Its king was also a ruler of many titles—king in Aragon, in Valencia, and the Balearic Isles (with one interval of separation), count of Barcelona, and in Provence. Marriage and inheritance had given him territorial rights in the south-east of France. Thus he came in contact with the crusaders of Simon de Montfort and the expansion of the French monarchy. Another marriage, that of Peter, the son and successor of James the Conqueror, with Costanza, the daughter of Manfred of Beneventum, gave him claims on the Neapolitan and Sicilian inheritance of the Hohenstaufen. From the date of the Sicilian Vespers (1283) Aragon is found mixed in the politics of Italy. The commercial activity of Barcelona brought it into collision with Genoa and alliance with Venice. The curious double position of the king of Aragon is fully illustrated by the career of that king Peter who was the father of James the Conqueror. He fought as a crusader at the Navas de Tolosa, he went to Rome to be crowned, and did voluntary homage to the pope. Yet his interests as a prince of southern France compelled him to draw the sword in defence of the Albigenses, and, orthodox as he was in creed, he fell fighting for them at Muret in 1213. If the fortunes of Aragon were to be followed in an outline of Spanish history, it would be necessary to wander as far as Athens and Constantinople.

The difference of the relations of these two states towards the comity of nations had corresponding internal distinctions. It has been already noted that eastern Spain was feudal. Therefore the distinction of classes was far sharper in Aragon than in non-feudal Castile and Leon. Predial slavery, which had disappeared in Castile and Leon in the 13th century, existed unmodified in Aragon, and in its worst form, down to the Bourbon dynasty. When we are told of the freedom of Aragon, it is well to remember that it was enjoyed only by the small minority who were personally free and also privileged: by the citizens of the towns which had charters—called in Aragon the Universidades—the nobles, the gentry and the Church. The Catalans attained emancipation from feudal subjection by a succession of savage peasant revolts in the 15th and 16th centuries. In Valencia emancipation was finally brought by a measure which in itself was cruel—the expulsion of the Moriscoes in the 17th century. The landlords were compelled to replace them by free tenants. The prevalence of predial slavery in Aragon and Valencia can be largely explained by the number of Mudéjares, that is Mahommedans living under Christian rule, and of Moriscoes—converted Mohammedans.

Christianization of Spain.

If now we look at the internal history of Spain from the conclusion of the period of the reconquest, which may be put in the middle of the 13th century, down to the union of the crowns of Castile and of Aragon by the marriage of Ferdinand and Isabel in 1469, it will be found to be occupied with two great processes. These two processes are firstly, the christianization of Spain, a very different thing from its reconquest from Moslem masters—and, secondly, not its unification, for that is hardly attained even now, but its progress towards unification.

When Fernando (Ferdinand III.), the conqueror of Andalusia, died in 1252, he was indeed the king of the two, or even the three, religions. The Jews and the Mahommedans formed a very large part of his subjects. We have no means of estimating their numbers, but there is much probability that together they formed not much less than a half of the population. The Jews, who had suffered cruelly from the brutal fanaticism of the Almohâdes, had done a great deal to forward the conquest of Andalusia. They were repaid by the confidence of the king, and the period which includes the reign of Fernando and lasts till the end of the 14th century was the golden age of their history in Spain. In 1391 the preaching of a priest of Seville, Fernando Martinez, led to the first general massacre of the Jews, who were envied for their prosperity and hated because they were the king's tax collectors. But the history of the persecution and expulsion of the Jews is the same everywhere except in date. The story of the Mudéjares and Moriscoes is peculiarly Spanish. In the Christian advance they were from the beginning first subjected and then incorporated. As far north as Astorga there is still a population known as the Maragatos, and familiar to all Spain as carters and muleteers. This marked type of the Leonese of modern times represents a Berber colony cut off among the Christians, and christianized at an early date, who went on using Arab and Berber names long after their conversion. They are only the most conspicuous example of a process which was common to all the Peninsula. As the Christians worked down to the south they found an existing Mahommedan population. To reduce them to pure slavery would, in the case of Castile at least, have been dangerous, and would also have been offensive to the Christians, who were themselves fighting for emancipation. To expel them would have been to have the soil untilled. Therefore the king, the nobles, the Church and the military orders combined to give them protection. For them, as for the Jews, the 13th and 14th centuries were a golden age. By the end of the 14th the persecutions began. Forced conversion prepared the way for expulsion, which came in the reign of Philip III. (1598–1621). But before the end was reached all had been persuaded or forced into Christianity, had ceased to be Mudéjares, and had become Moriscoes. In the majority of cases the conversion had occurred so long ago that the memory of the time when they were Mahommedans was lost, and multitudes of the children of Mudéjares remained. The Mozárabes again—the Christians who had always lived under Mahommedan rule—were an element of importance in medieval Spain. They had learnt to write in Arabic, and used Arabic letters even when writing Latin, or the corrupt dialect of Latin which they spoke. The conquest of Toledo by Alphonso VI. first brought the Christians into contact with a large body of these Arabized Spaniards, and their influence was considerable. By Alphonso they were favoured. He stamped his name on his coins in Arabic letters. It is said with probability that one of the early kings of Aragon, Peter I., could write no other letters than the Arabic. The Mozárabes were treated under the kings of the reconquest as separate bodies with their own judges and law, which they had been allowed to keep by the Moslem rulers. That code was the *forum judicum* of the Visigoths, the *fuero juzgo*, as it was called in the "romance" of later times and in Castilian. The Mozárabes brought in the large Arabic element, which is one of the features of the Castilian language. A part of the work of christianizing the Spain of the 13th century, and not the least part, was done by the monks of Cluny introduced by the French wife of Alphonso VI. To them was due the impulse given to the reform of the church, and to education. The foundation of the *studium generale* of Palencia in 1212 by Alphonso IX. was an outcome of the movement. It fell in the troubles following his death, but Fernando III. revived it by the foundation of the university of Salamanca, which dates from 1245. The church and the university were the great promoters of the effort to secure religious unity which began in the 14th and produced its full effects in the 17th century. How far the character, habits and morality of the Christian Spaniards were affected by Oriental influences is not a question which it is easy to answer. To some extent they no doubt were coloured. Such a social institution as the form of marriage known by the name of *barragania* shows visible traces of Eastern influence. In so far as it was a mere agreement of a man and woman to live together as husband and wife, it had precedents both Roman and Teutonic. There was also Roman and Teutonic example for recognizing the children of such a union as having rights of inheritance. On the other hand the name is Arabic, and so is the term applied to the children, *hijos de ganancia*, sons of the strange woman. Moreover the Oriental character of this union, be its origin what it may, is visible from the fact that it was polygamous. The only insuperable barrier to a *barragania* was the previous marriage "with the blessing," the full religious marriage, of the woman to another man. A married man might be united in *barragania* to a woman other than his lawful wife, and the children of that connexion, though not fully legitimate, were not bastards. The most signal example among many which could be quoted is that of Peter the Cruel (1350–1367), who, though married to Blanche of Bourbon, was *abarraganado* to Maria de Padilla. He left his kingdom to the daughters she bore him, and their *quasi* legitimacy was recognized not only by the Cortes during King Peter's life, but abroad. John of Gaunt, duke of Lancaster, married the elder of the daughters of Maria de Padilla, and claimed the crown of Castile by right of his wife. The clergy, who were debarred from the religious marriage by the discipline of the church, were commonly *abarraganado* all through the middle ages. The sumptuary laws, which required the *barraganas* of priests to wear a red border to their dresses, recognized them as a known and tolerated class.

The Jews and Mahommedans.

Expulsion of the Moriscoes.

The Mozárabes.

Problem of the Unification of Spain.

The work of political unification was essentially more difficult than the christianization of Spain. The great common institution of the church, common enthusiasms, prejudices and envies, were available for the second. The first had to contend with deeply rooted differences of national character and of class. The Galician who spoke, and still speaks, a language of his own, was profoundly separated from the Andalusian. The Basque, who till much later times practically included the Navarrese, was a man of another nationality and another speech from the Castilian. And what is true of Castile and Leon applies equally to Aragon. Aragonese, Catalans and Valencians were as different as Galicians, Basques, Castilians and Andalusians. Aragon spoke a dialect of Castilian. Catalonia and Valencia, together with the Balearic Islands, spoke, and speak, dialects of the southern French, the so-called Limosé, though it was not the language of the Limousin. And the causes of division did not end here. The word "commonwealth" had no meaning either east or west of the Iberian range. Every one of the kingdoms grouped round the two sovereigns who shared modern Spain was itself a loose conglomeration of classes. Mention has already been made of the Jew and the Mudéjar. These were more or less forcibly absorbed or brutally expelled. But the distinctions between noble and not noble, between town and country, were in the very fibre of all the Spanish peoples. Expulsion was impossible and combination only attainable by mutual agreement, and that was never secured. High mountain barriers and deep river courses had separated the Spaniards locally. They were more subtly and incurably separated by traditional and legal status. Speaking generally, and with the proviso that though names might differ from region to region, the facts did not; it may be said that Spain could be classified as follows: Under the crown of Castile all the territory was either *abadengo*, *realingo*, *salariego*, *behetria*, or it belonged to some town, big or little, which had its *carta pueblo* or town charter, its own *fuero* (forum) or law. *Abadengo* was land of the church, *realingo* domain of the crown, *salariego* land of the nobles. *Behetria* is less easy to translate. The word is the romance form of *benefactoria*. Behetrias, called "plebeian lordships," were districts and townships of peasants who were bound to have a lord, and to make him payments in money or in kind, but who had a varying freedom of choice in electing their lord. Some were described as "from sea to sea, and seven times a day," that is to say they could take him anywhere in the king's dominions from the Bay of Biscay to the Straits of Gibraltar, and change him as often as they pleased. Others were *de linage*, that is to say, bound to take their lord from certain lineages. Their origin must probably be sought in the action of communities of Mozárabes, Christians living under Moslem rule as *rayahs*, who put themselves under Christian chiefs of the early days of the reconquest for the *benefice* of their protection. They were mainly in old Castile. By the end of the middle ages they had disappeared. The chartered towns, in Spain east and west, were practically republics living under their own *carta pueblo* with their own *fuero* or law. All charters were not granted by the king. Many of them were given by nobles or ecclesiastics, but required the confirmation of the king. And in this country, where all was local law usage and privilege, where uniformity was unknown, all charters were not held by towns. In many cases the serfs in the course of their struggle for freedom extorted charters and *fueros*. The greater chartered towns had their surrounding *comarcas*, answering to the "county" of an Italian city, over which they exercised jurisdiction. In time the villages dependent on a chartered city, as they grew to be towns themselves, fought for, and in many cases won, emancipation, which they then sought to have confirmed by the king and proceeded to symbolize by setting up their own gallows in the market-place. The church had won exemption from the payment of taxes by no general law, but by particular privilege to this or that chapter, bishopric or monastery. The nobles claimed, and were allowed, exemption from taxation. Church and nobles alike were for ever extending their borders by purchase, or trying to do so by force. They conferred their exemptions on the land they acquired, thus throwing the burden of taxation on the towns and the non-nobles with increasing weight. But in this land, where nothing was consistent, there was in reality no sharp division except in the smaller and feudal portion—called Aragon for convenience—and save as between Christian and non-Christian, noble and non-noble. The necessities of the reconquest made it obligatory that all the dwellers

The Clergy and the Nobles.

on the frontier should be garrison. Hence they were not only encouraged but required to possess arms. Those of them who could provide themselves with a charger, a mail shirt, a spear and sword were ranked as *milites*—and the *miles* was a *caballero*. Alphonso VII. especially authorized all men who could arm themselves, mount themselves, and serve "cavalierly" to live as and count themselves "cavaliers." Hence the formation of the class of *caballeros de fuero*, non-nobles living "nobly" with a right to wear the sword. The privilege survived the epoch of the reconquest, and was often extended to gilds which the king wished to encourage. Hence came the practice which caused so much surprise and amusement to French and German travellers of the 16th and 17th centuries—the wearing of the gentlemanly sword by the artisans of towns.

The Caballeros de Fuero.

No general law controlled these local usages and *fueros*. The *fuero juzgo* (*forum judicum*) was accepted by the Mozárabes, and had authority everywhere in cases not provided for by the charters, or where no privilege had been granted by the king. But it was subject to innumerable exceptions, and particular jurisdictions. There was no common tribunal. Nor was any material change introduced after the epoch of the reconquest. Alphonso X., El Sabio or Learned, made a *fuero real*, which was formed by combining the best parts of existing charters. It was accepted by towns and districts not already chartered, but by them only. The famous *siete partidas* (the seven divisions), drawn up about 1260, is often spoken of as a code of laws. It was never so treated till it was promulgated at the Cortes of Alcalá in 1338, in the reign of his great grandson, Alphonso XI. Even then it was subject to the restriction that it was not to prevail against any *fuero*, or the *fuero real*. The Cortes might have been expected to forward the work of unification. But without going into details on a subject which requires particular treatment, it may be noted that the Cortes was no more coherent, or fixed in constitution or working, and was no more national, than any other of the institutions of the country. The crown of Castile and Leon had indeed a common Cortes after 1301. Aragon never advanced so far. It, Catalonia and Valencia had each their Cortes, which never united. When King Philip IV. (1621–1665) wished to secure grants of money from these parts of his dominions he had to summon three separate Cortes, which sat in different frontier towns, and he had to negotiate simultaneously with all three. Then the Spaniards, in their carelessness of form and regularity, never fixed any rule as to the constitution of a Cortes. The third estate secured representation in the Cortes of Leon (1188), and then in Castile and the Common Cortes. In the kingdom of Aragon the right was secured about the same time. It was decided that no new tax could be imposed save with the consent of the commons, and that therefore they must be represented. But no rule was ever made as to whom the king was bound to summon, nor even that the presence of the clergy and the nobles was necessary to constitute a true Cortes. It was never claimed by the Cortes that its consent was necessary to the making of laws. The Roman maxim that what the "prince" wills has the force of law was not disputed—nor did the Spaniard doubt that the king acting by himself was "the prince." The check which the *justiza*, or chief justice, of Aragon imposed on the king was supported by the force of nobles and cities, but it was an exception in Spain. The representatives of the commons were the *personeros* and *procuradores*, *i.e.* attorneys of the cities. There was no knight of the shire in any Spanish Cortes. The great cities in Castile and Leon succeeded finally in reducing the right of representation to a privilege of eighteen among them, with the good will of the king, who found it easier to coerce or bribe the procurators of eighteen towns than the representatives of a hundred and fifty. The legislative work of such bodies was necessarily small. Their practical power might be great when the king was weak and necessitous, but only then.

Local Laws.

The Siete Partidas.

The Cortes.

It ought to have been easy for kings whose authority was confessedly so great to have made themselves effectively despotic amid all this division and weakness. Nor would they have failed so to do if the sovereigns of Castile had not been either incapable or short-lived, and if there had not been an extraordinary succession of long minorities; while the kings of Aragon were tempted to neglect their Spanish possessions because they were in pursuit of their claims and ambitions in Italy. Alphonso X. of Castile (1252–1284) was an admirable writer, and a man of keen intelligent interest in science and law. As a ruler he was at once weak, unstable and obstinate. He wasted much time and great sums of money in endeavouring to secure his election as emperor—not in Spain, but in the Holy Roman Empire. He did indeed add the town of Cadiz to his possessions with the help of his vassal, the Moorish king of Granada, but his reign is filled with quarrels between himself and his nobles. The nobles of Castile and Leon were not feudal vassals, but great landowners claiming and exercising rights of jurisdiction on their estates. Their name of *ricos hombres*, which first appears in written documents of the 12th century, has been credited with a Teutonic origin, but it was in all probability nothing but a "romance" or Castilian translation of the *seniores* and *senatores*, *potentiores* and *possessores* of the Visigoth councils and code. They represented a nobility of wealth and not of blood. In the earlier times their possessions were divided among their sons. It was only at the end of the 13th century and later that they began to form *mayorazgos* or entails, to preserve their name and family. It was then that *segundones*, or younger sons, began to be known in the social life of Spain. But whatever their position may have been legally, they were as grasping as any feudal nobility in Europe, and they were singularly destitute of any capacity for combined political action. In Aragon, indeed, the nobles did extort a promise from the king that they should not be put to death or deprived of their estates by his mere decision. In Castile they never went beyond begging or extorting grants of the crown lands, or pensions charged on the royal revenue. Alphonso X. ended his life in a civil war with his son Sancho, who claimed the succession in preference to the children of his elder brother, Fernando de la Cerda, and in virtue of a doctrine of which much was heard in the middle ages elsewhere than in Spain. He maintained that the younger son, being nearer to the father than the grandson, had a right to succeed in preference to the children of an elder brother who had died before the succession was open. Alphonso, after first accepting Sancho's claim, repudiated it, and made a will by which he not only left the crown of Castile to the eldest son of Fernando de la Cerda, but cut vassal kingdoms out of the southern parts of Spain for Sancho's younger brothers. The reign of Sancho IV., surnamed El Bravo, or the Fierce (1284–1296), was one constant struggle with the very nobles who had helped him against his father, with his younger brothers, and with the sons of Fernando de la Cerda. Murder and massacre were his familiar methods. He was succeeded by his infant son Fernando (Ferdinand IV.), whose long minority was an anarchy, tempered by the courage and the tact of his mother, Maria de Molina. Fernando, ungrateful to his mother and incapable as a king, died in 1312, leaving a son of less than a year old, Alphonso XI. (1312–1350). After another minority of confusion, Alphonso, surnamed "of the Rio Salado," from the great victory he won over an invading host from Africa, ruled with energy and real political capacity. He was indeed ferocious, but such actions as the murder of his great-uncle, Don Juan El Tuerto—the distorted in body and mind—did not seem to his subjects more than the exercise by "the prince" of that right to act for the good of the state *legibus solutus* which is inherent in sovereignty. But Alphonso did not use his freedom to act *legibus solutus* except against such hoary and incorrigible intriguers as Don Juan el Tuerto or the Caballero Diego Gil, whom he beheaded with seventeen of his men after promising them security for their lives. He did something to found the judicial and administrative unity of the country. His death at the age of thirty-eight, during the great plague, and while he was besieging Gibraltar, was a misfortune to Spain. His successor, Peter, surnamed the Cruel (1350–1368) was destined to show the Castilians exactly what the constant use by "the prince" of the reserved rights of the sovereign authority could be made to mean, when they were exercised by a passionate man maddened by suspicion of all about him. Administering the civil side of his government through Jewish tax-gatherers and farmers of the taxes, and surrounded by the Mudéjar guard, who were the executors of his justice, his path is marked by one long succession of murders. With all his appearance of energy, he shrank from action at the critical moment of his wars out of utter want of trust in all about him. His expulsion by his brother, Henry of Trastamara, the eldest son of Leonora de Guzman, his restoration by the Black Prince (*q.v.*), his treachery

to him, and his final defeat and murder at Montiel, are famous episodes. Henry of Trastamara, the beginner of the "new kings" (1368–1379), reigned by election. The nobles and the cities to whom he owed his crown had proportionate power. In his reign and those of his immediate successors the Cortes flourished, although it failed to establish checks on the absolute power of the king. Henry was on the whole a successful ruler. He forced his neighbours of Portugal to make peace, his fleet defeated an English squadron off Rochelle, and he restored internal order. The civic *hermandades*, or brotherhoods, enforced respect from the nobles. John I. (1379–1390), Henry's son and successor, had to contend with John of Gaunt, son of Edward III. of England, who had married the eldest daughter of Peter the Cruel, and claimed the crown of Castile in her name. John averted the danger by arranging a marriage between his son Henry and Constance, the eldest daughter of John of Gaunt, an alliance which united the two equally illegitimate lines representing Alphonso XI., and so closed the dispute as to the succession. He was less fortunate in his efforts to vindicate the rights of his wife Beatrix to the throne of Portugal. The defeat of the Castilians at the battle of Aljubarrota (1385) compelled the king to renounce his pretensions. The minority of his son, Henry III. (1390–1406) was long, and his effective reign short, but in the brief space allowed him the king, a weakly man surnamed El Doliente (the sufferer) did something to establish order. He recovered all the immense grants of crown lands and rents, impounded by the nobles during his minority. The first years of the minority of his infant son, John II. (1406–1454), were by a rare exception peaceful. The young king's uncle Ferdinand (called "of Antequera" because he was besieging that town, which he took from the Moors, when he heard in 1412 that he had been declared heir to the crown of Aragon by the Cortes of Caspe) acted as regent. Ferdinand was able and honest. His succession to the throne of Aragon is an event of capital importance in the history of the Peninsula.

John I., 1379–1390.

Henry III., 1390–1406.

John II., 1406–1454.

The kings of Aragon from the death of James the Conqueror in 1276 to the death of Martin I. in 1410 were so largely concerned in the struggle with the Angevin party in Naples and Sicily, that their history belongs rather to Italy than to their Peninsular kingdom. They were six in number: Peter III. (1276–1285), Alphonso III. (1285–1291), James II. (1291–1327), Alphonso IV. (1327–1336), Peter IV. (1336–1387), John I. (1387–1395), and Martin I. (1395–1410). In so far as their influence was felt in the internal affairs of their Spanish kingdoms, they had a double task to perform. The first was to reunite the Balearic Islands and Roussillon, which James the Conqueror had left by will to a younger son, to the crown of Aragon. This was finally achieved, after a hideous story of fratricidal hatred and murder by poison, by Peter IV. Their second task was to reduce their turbulent barons, in Aragon, Catalonia and Valencia alike, to the position of obedient subjects. In this task also it was Peter IV. who achieved success. The barons of Aragon and Valencia had extorted from his weak father the charter known as the Union, which not only recognized their just right not to be punished in life or property, except by process of law, but explicitly authorized them to elect the *justiza* or the chief justice, whose decisions were to be independent of royal confirmation, and to take up arms whenever they considered themselves aggrieved. Such an instrument was of course incompatible with the monarchical or any other form of government. The object of the life of Peter IV. was to force the barons to surrender their charter. After years of struggle and preliminary failures, Peter IV. defeated the "Union" utterly at the decisive battle of Epila (1348). He was a typical king of the 15th century, immeasurably false, and unspeakably ferocious, but he was not a mere blood-thirsty sultan like his enemy, Peter the Cruel of Castile. When he won he took indeed a brutal vengeance on individuals, and he extorted the surrender of the charter and destroyed it with his dagger in the presence of the Cortes at Saragossa. He cut his hand in his eagerness, and declared that the blood of a king was well shed in securing the destruction of such an instrument —whence his popular nickname of Peter of the Dagger (del Punejalet). But his use of the victory was statesmanlike. He fully confirmed the right of the nobles to trial by law and security against arbitrary punishment; he left the franchises of the city untouched, and respected the independence of the *justiza*. The result of his victory was to give Aragon and his other dominions a measure of internal peace unknown in Castile. The reigns of his sons and successors, John and Martin, were insignificant and tranquil. The death of Martin without children in 1410 left the succession open. The two years of discussion which followed are interesting as a proof that Aragon had reached a higher political level than Castile. The Cortes was able to administer in peace, and the question of the succession was debated as if it had been in a suit between private persons. The judges finally decided in favour of Ferdinand, on the ground that his mother, Eleanor, was the daughter of Peter IV., and that though a woman could not reign as a "proprietary queen" in Aragon, she could convey the right to her husband or transmit it to her son. On their own principles they ought to have given the crown to John of Castile as the son of Ferdinand's elder brother. But the countries were not ripe for union Nevertheless the choice of Ferdinand was a step forward towards union.

The Kings of Aragon.

Peter IV. and the "Union."

The Succession in Aragon.

From 1412 to 1479 the separation lasted with a growing approximation of the two states whose interests touched one another so closely. In Castile John II. (1406–1454), a man of amiable but indolent character and of literary tastes, was governed by his favourite, Álvaro de Luna, and harassed by his nobles. His reign is full of contentions which were not wars for a principle, but were scuffles for the control of the spigot of taxation. At the end of his life he sacrificed his favourite at the instigation of his second wife, an act which, it is said, justly embittered his last days. Of his son, Henry IV. (1454–1474) it is enough to say that he was called "the Impotent," and that there is every reason to believe that he deserved the description in all the senses of the word. His reign was an inferior copy of his father's. As the legitimacy of his alleged daughter Juana was disputed, his sister Isabella claimed the succession, and married her cousin, Ferdinand of Aragon, son of John I., in 1469 in defiance of her brother. In Aragon, Ferdinand I. "of Antequera" (1412–1416) was succeeded by Alphonso V. (1416–1458) the Magnanimous, whose brilliant life belongs to Italy. In Aragon he was represented by his brother John, who administered as lieutenant-general, and who reigned in his own right (1458–1479) when Alphonso V. died without legitimate heirs, leaving Naples by will to a bastard son. John I., a man of indomitable energy and considerable capacity, spent most of his life in endeavouring to enforce his claims to the kingdom of Navarre as the husband and heir of its queen Blanche. His conflict with his son by his first marriage, Charles, prince of Viana, was settled in his favour by the death of the prince. Then he had to contend with a national revolt in Catalonia, which endeavoured to make itself independent under three successive foreign princes. In the end the pertinacity of John triumphed. At the age of over eighty, blind and unconquerable, he transmitted his kingdom to Ferdinand, his son by his second marriage, with Juana Enriquez, of the family of the hereditary admirals of Castile. Navarre went to a daughter, and Roussillon was somewhat fraudulently retained by Louis XI. as security for a debt. Ferdinand conquered the Spanish half of Navarre later, and recovered Roussillon from Charles VIII., the successor of Louis XI.

Castile. John II., 1406–1454.

Henry IV., 1454–1474.

Aragon.

John II., 1458–1479.

With the death of John II. of Aragon in 1479 the history of Spain enters on an entirely new period. Hitherto it has been the story of a national development. The process did not cease, but, during the reign of Isabella the Catholic (1474–1504) until the death of her husband Ferdinand in 1516, was carried, not to completion, but to the stopping place at which it was destined to rest for two centuries. The voyage of Columbus in 1492, and the intervention of Ferdinand in the great conflict of France, the empire and the papacy for predominance in Italy, had, simultaneously, the effect of opening to her the world of conquest and adventure in America, and of committing her to incessant wars in the Italian Peninsula. The death of John, the only son of Ferdinand and Isabella, the worst misfortune which ever happened to Spain, opened the succession to all the crowns and coronets worn by the Catholic sovereigns to Charles of Habsburg—the emperor Charles V. From that day Spain became a part—the leader, then the paymaster, then the dupe—of the international monarchical confederation called "the illustrious House of Austria." The Spaniard became the swordsman and executioner of the counter-Reformation, because the power of the House of Austria depended on the imposition of religious unity in Europe. The decision of Charles V., king of Spain and emperor, to leave the Netherlands to his son Philip II., committed the Spaniards to conflict on the sea with England, and to the insane attempt to secure a safe road for their armies across Europe from the shores of the Mediterranean to the North Sea. Thereby they threatened the very national existence of France. The arrangement was made possible only by the hopeless divisions of Germany, the blind pride of Spain, and the utter political incapacity of both. It forced every patriotic ruler of England to oppose Spain on the sea, and every statesmanlike master of France to ruin her power on the land. Meanwhile the Spaniards were endeavouring to check the advance of the Turks in the Mediterranean, and to exclude all Europe from the waters of the New World. In the intensity of their struggle with the Reformation they subjected education to a censorship which, in order to exclude all risk of heresy, stifled thought and reduced knowledge to the repetition of safe formulas. With their eyes on the ends of the earth, and a ring of enemies from Constantinople to the Antilles, the Spaniards fought, with steadily diminishing material resources, with a character and intellect which shrivelled by swift degrees. When nearly bled to death for the illustrious House of Austria, they were transferred to the House of Bourbon, which in its turn dragged them into conflict with Austria in Italy and England on the sea. At the beginning of the 19th century they had fallen into such a state of weakness that Napoleon could, with some considerable measure of excuse, look upon their country as a species of no-man's-land into which his troops had only to march on police duty to secure immediate obedience. The history of the 19th century is the liquidation of an enormous bankruptcy, and the completion of the circle which confines the Spaniard once more to the soil of the Peninsula.

Spanish History after 1479.

Ferdinand and Isabella were proclaimed king and queen of Castile together, although the crown was hers alone, and although she never consented to part with her sovereign authority. In the purely internal affairs of Castile it was always she who decided on questions of administration. Some opposition was offered by a faction of the nobles who took up the claims of Henry's supposed daughter, commonly called Juana la Beltraneja, because her father was alleged to have been Don Beltran de la Cueva, who, however, fought for Isabella. Juana's party had the support of the king of Portugal, who arranged a marriage between her and his son. The defeat of the Portuguese at Toro made an early end of the war. The new sovereigns immediately began the work of establishing order and obedience in their dominions. The line of policy followed by the Catholic sovereigns[1] was to keep the old forms, but draw the substance of power to themselves. Thus, for instance, they organized a police to clear the country of brigands, and attached a special jurisdiction to it, but they gave it the old name of *Hermandad* and the very superficial appearance of a voluntary association of the cities and the gentry. It consisted of a force of well-appointed horsemen, in the proportion of one to every hundred families. Its merits as a police have perhaps been exaggerated, and in the war with Granada its bands were employed as soldiers. But an end was at least put to the existence of *peñas bravas* in the dominions of the crown of Castile. And this was the uniform model of their policy. The masterships of the military orders of Calatrava, St Iago and Alcántara were one by one annexed to the Crown. Their commandaries were used to pay, or pension, the servants of the sovereigns. No attack was made on the charters of the towns, but in Castile and Aragon alike royal officers were appointed to adjudicate on disputes within the corporations themselves, or between corporation and corporation. By them the old councils were rapidly reduced to a state of atrophy. The same course was followed with the Cortes. It continued to be summoned by the Catholic sovereigns and their successors of the Habsburg line, but it was needed only to grant money. The nobles and the clergy, who as exempt from taxation had no vote, became purely ornamental parts of the Cortes. The representatives of the third estate were confined by the indifference of the Castilians to eighteen towns, whose procurators were named by the councils either from among themselves in rotation, or from particular families. Moreover, they received pay from the Crown while the Cortes sat. For the work of legislation the Cortes was not needed, and never had been. It was not even summoned during the whole of the war with Granada. The Catholic sovereigns provided themselves with a revenue by the customary wholesale resumptions of grants made during the reigns of John II. and Henry IV., and by the suppression or reduction of the pensions they had granted with profusion. The nobles, having been brought to obedience by a frown, were left in possession of their estates, their social rank and the obligation to render military service. They were summoned to the royal council, but only as ornamental members, the real authority and the exclusive right to vote being confined to the *letrados*, or lawyers, chosen by the Crown from the class of the burghers. Encouragement of industry was not wanting; the state undertook to develop the herds of merino sheep, by issuing prohibitions against inclosures, which proved the ruin of agriculture, and gave premiums for large merchant ships, which ruined the owners of small vessels and reduced the merchant navy of Spain to a handful of galleons. *Tasas*, fixed prices, were placed on everything. The weaver, the fuller, the armourer, the potter, the shoemaker were told exactly how to do their own work. All this did not bear its full fruit during the reign of the Catholic sovereigns, but by the end of the 16th century it had reduced Spain to a state of Byzantine regulation in which every kind of work had to be done under the eye and subject to the interference of a vast swarm of government officials, all ill paid, and often not paid, all therefore necessitous and corrupt. When the New World was opened, commerce with it was limited to Seville in order that the supervision of the state might be more easily exercised. The great resource of the treasury was the *alcabalas* or excises—taxes (farmed by contractors) of 5 or 10% on an article every time it was sold—on the ox when sold to the butcher, on the hide when sold to the tanner, on the dressed hide sold to the shoemaker and on his shoes. All this also did not bear its full fruit till later times, but by the 17th century it had made Spain one of the two "most beggarly nations in Europe"—the other being Portugal.

Ferdinand and Isabella.

Government of the "Catholic Sovereigns."

The policy of the Catholic sovereigns towards the Church was of essentially the same character as their treatment of the nobles or the cities. They aimed at using it as an instrument of government. One of the first measures adopted by them in Castile, before the union with Aragon, was to stop the nomination of foreigners to Spanish benefices by the pope. But the most characteristic part of their ecclesiastical policy was the establishment of the Spanish Inquisition (*q.v.*). By the bull of Sixtus IV. of 1578 they obtained authority to appoint three inquisitors, whom they were empowered to remove or replace, and who were independent of, and superior to, the inquisitorial courts of the bishops.

The Spanish Inquisition.

[1] The name was not formally given to them by the pope till later, but it is convenient to use it at once.

The Spanish Inquisition was a department of the royal government, employed to enforce religious unity and obedience, because they were held to be indispensable in order to obtain national unity and to enforce the authority of the Crown. The Inquisition was at first established (in 1480) in the dominions of Castile only, but it was extended in 1486 to Catalonia and in 1487 to Aragon, in spite of strong protests. The first duties of the Inquisition were to deal with the converted Jews and Mahommedans, respectively known as Marranos and Moriscoes, and with those who still professed their religions. The latter were dealt with by expulsion, which in the case of the Jews was enforced in 1492, and in the case of the subject Mahommedans or Mudéjares in 1502. Both were industrious classes, and the loss of their services was disaster to Spain—the first of a long series of similar measures which culminated in the final expulsion of the Moriscoes in 1610. The converted Jews and Mahommedans presented greater difficulties to the Inquisition. Many of the higher ecclesiastics and of the nobility were of Jewish, or partially Jewish, descent. The landlords who found the Moriscoes useful tenants, and the commercial authorities of towns like Barcelona, who knew the value of the converted Jews, endeavoured to moderate the zeal of the inquisitors. But they were supported by the Crown, and there can be no question that the Holy Office was popular with the mass of the nation. It produced a wholesale flight of the converted Jews to France.

In social life the religious zeal favoured by the Inquisition led to such things as those public processions of flagellants which went on in Spain till the end of the 18th century. It aimed at preserving orthodoxy and developing sainthood on the medieval model. Of ordinary immorality it took little notice, and the triumph of its cause in the 16th and 17th centuries, while producing such types of ecstatic piety as St Theresa (*q.v.*), the Sor Mariade Jesus (Maria Agreda), (*q.v.*) and the Venerable Virgin Luisa de Carvajal (*q.v.*), was accompanied by an extraordinary development of moral laxity. The Holy Office showed equal zeal in extending its jurisdiction, and by the end of the 17th century had provoked a strong reaction. The most honourable passage in its history is the part it took in forwarding the great, though temporary, reform of the monastic orders, which was a favourite object with Queen Isabella.

Conquest of Granada, 1492.

Between 1481 and 1492 the Catholic sovereigns completed the work of the reconquest by subjugating the one surviving Mahommedan state of Granada. Their task was materially facilitated by dissensions among the Moors, whose princes intrigued against one another, and were to the last ready to aid the Christians in the hope of obtaining a small fragment of territory for themselves. The surrender of Granada on the 2nd of January 1492 was partly secured by promises of toleration, which were soon violated. A revolt had to be suppressed in 1501. Having secured the unity of their territory in the Peninsula, the Catholic sovereigns were free to begin the work of expansion. In 1492 Columbus (*q.v.*) sailed on his first voyage to the west. In 1493 Ferdinand secured the restoration of Roussillon from Charles VIII. of France by the fallacious treaty in which he undertook to remain neutral during the king's expedition to Italy. The voyage of Columbus had unforeseen consequences which led to diplomatic difficulties with Portugal, and the treaty of Tordesillas in 1494, which defined the respective spheres of influence of the two powers in the New World and in Asia.

Discovery of America.

Foreign Policy of Ferdinand and Isabella.

In 1497 Ferdinand, with the support of his wife, entered on those wars of Italy in which the Spanish regular soldiers first gained their reputation, and which made Spain for a time the dominant power in the Italian peninsula (see Córdoba, Gonzalo F. de). They endeavoured to strengthen themselves against France by marriages with the royal family of England (see Catherine of Aragon) and the Habsburgs. The marriage of Juana, called the Mad, with Philip of Habsburg, son of the emperor Maximilian (*q.v.*) brought a new dynasty to Spain. On the death of the queen in 1504 her son-in-law claimed the regency, and was supported by the Castilian nobles. His death in 1506 and the insanity of his widow left the Castilians no choice but to restore Ferdinand as regent. During the next ten years Ferdinand governed with the very able assistance of the archbishop of Toledo, Jimenes de Cisneros (*q.v.*). He annexed the southern part of Navarre, which was held by the representatives of his half-sister. The archbishop organized and directed the expedition which conquered Oran, Tripoli and other points on the African coast. Here beyond all doubt lay the proper field for the expansion of Spain. She was drawn from it on the death of Ferdinand in 1516. He was succeeded by his grandson Charles of Habsburg, and when Charles was elected to the empire in 1519 Spain was dragged into the wars and politics of central Europe.

Sole Reign of Ferdinand.

Charles I. of Spain, V. as Emperor.

Only the smaller part of the reign of Charles was spent in Spain. He came to it from Flanders, where he had received his education, unable to speak the language and surrounded by Flemish favourites. To him and them the country was only a source of supply from which money was to be obtained in order to bribe the German electors. The disregard which both showed for the interests of Spain and its constitutional rights led to the outbreak of the revolt of the cities—the *Comuneros*—which plunged Castile into confusion in 1519 and 1520 after the departure of Charles for Flanders. The rising of the *Comuneros* has often been spoken of as a struggle for freedom. But it has a very dubious right to the name. In many places the movement was simply an excuse for a revival of private wars between wealthy noble families. In others it was a struggle to enforce the claims of particular towns. It hardly extended as a political movement beyond the two Castiles. If its leaders had acted together, in combination with the nobles, the *Comuneros* could have imposed their own terms, for there was no royal army to oppose them. But they drifted into hostility with the nobles, and were defeated by them at Villalar. The movement then rapidly collapsed. Charles had no part in the suppression of the revolt. Throughout his reign he respected the claim of the Cortes that no new taxation should be raised without its consent, but as he had to deal only with the representatives of eighteen cities, who could generally be bribed, he rarely failed to secure what he demanded.

Revolt of the Comuneros, 1519–20.

Rising of the Germania in Valencia.

The outbreak of the *Comuneros* in Castile coincided with the social and agrarian revolt in Valencia known as the *Germania* or brotherhood, from the name of the directing committee appointed by the insurgents. It was in no sense a movement for political rights, but an attack by the sailors, the workmen of the towns, and the Christian peasants on the landowners and their Mudéjar and Morisco serfs. It was accompanied by murder and massacre and by forced conversions of the Mudéjares. After desolating Valencia for some three years it was put down by the help of troops from Castile.

Spain and the European Policy of Charles V.

The conquest of Mexico by Hernan Cortes (*q.v.*) and of Peru by Francisco Pizarro (*q.v.*) belong to this reign, but were immediately due to the adventurers in America. These conquests and the incessant wars into which Spain was drawn by the Aragonese claims in Italy, and its connexion with the empire, gave to the nation a great European position and to the Spanish soldiers of the time many opportunities to win renown. The capture of the French king at Pavia and his imprisonment at Madrid gratified the pride of the Spaniards, and did much to reconcile them to the sacrifices which the policy of the emperor imposed on them. Except, however, in the case of the successful attack on Tunis in 1535, and the attempt to take Algiers in 1541, his actions were not inspired by any regard for the interests of his Spanish kingdoms. He treated them simply as instruments to promote the grandeur of his house. His indifference to their good, or his utter inability to see where it lay, was conspicuously shown when, on his abdication in 1556, he left his hereditary Flemish possessions to his son Philip, and not to his brother Ferdinand.

Philip II., 1556–1598.

The reign of Philip II. (1556–1598) was a prolongation of the reign of his father, both in domestic and in foreign policy. In it the vices of this policy were displayed to the fullest extent. Philip's marriage with Mary Tudor (*q.v.*) in 1554 having proved barren, and her death in 1558 having placed Elizabeth on the throne of England, he was left without the support against France which this union was meant to secure. At the same time his inheritance of the Netherlands brought him into collision with their inhabitants, who feared his absolutist tendencies, and with the Reformation.

The revolt in the Low Countries was inevitably favoured by both France and England. Philip was consequently drawn into intervention in the religious wars of France (*q.v.*) and into war with England, which culminated in the great Armada (*q.v.*) of 1588. His relations with England were further complicated by the extension of English maritime enterprise to the New World (see HAWKINS, JOHN; and DRAKE, FRANCIS). In the Mediterranean he was equally forced by his position to take a part in resisting the Turks (see MALTA: *History*; and LEPANTO, BATTLE OF). But the key to his whole policy must be sought in his relations to his Flemish subjects. With his absolutist tendencies he was bound to wish to govern them as he did Castile, and the principle of religious toleration, which was not understood by any prince in Europe with the exception of the prince of Orange, William the Silent (*q.v.*), was peculiarly impossible for him. His reign was therefore one long struggle with forces which he was unable to master.

Spain and the Netherlands, France and England.

The burden of the struggle fell with crushing effect on his Spanish dominions and peculiarly on Castile. Aragon, which was poor and tenacious of its rights, would give little; Catalonia and Valencia afforded small help. The Flemish revenue was destroyed by the revolt. The Italian states barely paid their expenses. Resources for the incessant wars of the reign had been sought in the taxation of Castile and the revenue from the mines of America. They were wholly inadequate, and the result of the attempt to dominate all western Europe was to produce bankruptcy and exhaustion. In his internal government Philip was fully despotic. He made no pretence of consulting the Cortes on legislation, and though he summoned them to vote new taxes he established the rule that the old were to be considered as granted for ever, and as constituting the fixed revenue of the Crown. The nobles were excluded from all share in the administration, which was in the hands of boards (*juntas*) of lawyers and men of the middle class. All business was conducted by correspondence, and with a final reference to the king, and the result was naturally endless delay.

Character of Philip's Government.

The first years of the reign of Philip II. were occupied in concluding the last of his father's wars with France, to which was added a very unwelcome quarrel with the pope, arising out of his position as duke of Milan. He was unable to avoid sending an army under Alva against Paul IV., and was glad to avail himself of the services of Venice to patch up a peace. On the Flemish frontier, with the help of an English contingent and by the good generalship of Philibert of Savoy he defeated a French army at St Quentin on the 10th of August 1557, and again at Gravelines on the 13th of July 1558. But he did not follow up his successes, and the war was ended by the signing of the peace of Cateau Cambrésis on the 2nd of April 1559. The exhaustion of his resources made peace necessary to him, and it was no less desirable to the French government. Philip's marriage with Elizabeth, the daughter of Henry II. and of Catherine de Medici, together with their common fear of the Reformation, bound him for a time to the French royal house. In August 1559 he returned to Spain, which he never left for the rest of his life. The outcry of the Cortes, whether of Castile or of the other states, for relief from taxation was loud. In some cases the king went so far as to levy taxes in what he acknowledged was an illegal manner and excused under the plea of necessity. By 1567 the revolt in the Netherlands was flagrant, and the duke of Alva was sent with a picked army, and at the expense of Spain, to put it down. In the following year the tyranny of the Inquisition, encouraged by the king who desired to purge his kingdom of all taint of heterodoxy, led to the revolt of the Moriscoes, which desolated Granada from 1568 to 1570, and ruined the province completely. The Moriscoes had looked for help from the Turks, who were engaged in conquering Cyprus from Venice. The danger to Spain and to the Spanish possessions in Italy stimulated the king to join in the Holy League formed by the pope and Venice against the Turks; and Spanish ships and soldiers had a great share in the splendid victory at Lepanto. But the penury of the treasury made it impossible to maintain a permanent naval force to protect the coast against the Barbary pirates (*q.v.*). Andalusia, Murcia, Valencia, Catalonia and the Balearic Islands were subject to their raids throughout the whole of the 16th and 17th centuries. In 1581 Philip annexed Portugal, as heir to King Henry, the aged successor of Dom Sebastian. Philip endeavoured to placate the Portuguese by the fullest recognition of their constitutional rights, and in particular by favouring the *fidalgos* or gentry. The duke of Braganza, whose claims were better than Philip's, was bought off by immense grants. Spain seemed now to have reached a commanding height of power. But she was internally exhausted. Her real weakness, and the incompetence of her government, were shown when open war began with England in 1585. While a vast armament was being slowly collected for the invasion of England, Drake swept the West Indies, and in 1587 burnt a number of Spanish ships in their own harbour of Cadiz. The ruinous failure of the great Armada in 1588 demonstrated the incapacity of Spain to maintain her pretensions. In 1591 the support given by the Aragonese to Antonio Perez (*q.v.*) led to the invasion of their country by a Castilian army. The constitutional rights of Aragon were not entirely suppressed, but they were diminished, and the kingdom was reduced to a greater measure of submission. In his later years Philip added to all his other burdens a costly intervention in France to support the league and resist the succession of Henry IV. to the throne. He was compelled to acknowledge himself beaten in France before his death on the 13th of September 1598. He left the war with England and with the Netherlands as an inheritance to his son.

Foreign Policy of Philip.

Exhaustion of Spain.

The period of one hundred and two years covered by the reigns of Philip III. (1598–1621), Philip IV. (1621–1665) and Charles II. (1665–1700), was one of decadence, ending in intellectual, moral and material degradation. The dynasty continued to make the maintenance of the rights and interests of the House of Austria its main object. Spain had the misfortune to be saved from timely defeat by the weakness of its neighbours. The policy of James I. of England (*q.v.*), the civil wars of Charles I. (*q.v.*), the assassination of Henry IV. of France, the troubles of the minority and reign of Louis XIII. (*q.v.*) and the Fronde (*q.v.*), preserved her from concerted and persistent foreign attack. After a futile attempt to injure England by giving support to the earl of Tyrone in Ireland (see TYRONE, EARLS OF) peace was made between the powers in 1604. In 1609 a twelve years' truce was made with the Dutch. But the temporary cessation of foreign wars brought no real peace to Spain. In 1610 fears of the help which the Moriscoes might give to a Mahommedan attack from Africa combined with religious bigotry to cause their expulsion. The measure was thoroughly popular with the nation, but it was industrially more injurious than a foreign invasion need have been. The king was idle and pleasure-loving. He resigned the control of his government to the duke of Lerma (*q.v*), one of the most worthless of all royal favourites. The expenses of the royal household increased fourfold, and most of the increase was absorbed by the favourite and his agents. The nobles, who had been kept at a distance by Philip II., swarmed round the new king, and began to secure pensions in the old style. The pillage was so shameless that public opinion was stirred to revolt. Some of the lesser sinners were forced to restitution, and in 1618 Lerma fell from power, but only because he was supplanted by his son, the duke of Uceda, a man as worthless as himself. In that year was taken the step which was destined to consummate the ruin of Spain. The Thirty Years' War began in Germany, and Spain was called upon to support the House of Austria.

Philip III., 1598-1621.

The death of Philip III. on the 21st of March 1621 brought no real change. His son, Philip IV., was an abler man, and even gave indications of a wish to qualify himself to discharge his duties as king. But he was young, pleasure-loving, and wanted the strength of will to make his good intentions effective.

Philip IV., 1621–1665.

For twenty years the administration was really directed by his favourite the count of Olivares (*q.v.*) and duke of San Lucar, known as the "Conde Duque," the count-duke. Olivares was far more able and honest than Lerma. But he could only keep his place by supplying his master with the means of dissipation and by conforming to his dynastic sentiments. The truce concluded in 1609 with Holland ended in 1621, and was not renewed. The commercial classes, particularly in Portugal, complained that it subjected them to Dutch competition. War was renewed, and the Dutch invaded Brazil. As their fleets made it dangerous to send troops by sea to Flanders, Spain had to secure a safe road overland. Therefore she endeavoured to obtain full control of the Valtellina, the valley leading from Lombardy to Tirol, and from thence to the German ecclesiastical states, which allowed a free passage to the Spanish troops. War with France ensued. The failure of the treaty of marriage with England (see Charles I. and Buckingham, First Duke of) led to war, for the English court was offended by the Spanish refusal to aid in the restoration of the count palatine, son-in-law of James I., to his dominions. In Flanders the town of Breda was taken after a famous siege. The French conducted their campaign badly. The Dutch were expelled from Bahia in Brazil, which they had seized. An English attack on Cadiz in 1625 was repulsed. His flatterers called the king Philip the Great. A few years later it began to be a standing jest that he was great in the sense that a pit is great: the more that is taken from it the greater it grows. By 1640 the feebleness of the monarchy was so notorious that it began to fall to pieces. In that year Portugal fell away without needing to strike a blow. Then followed the revolt of Naples (see Masaniello) and of the Catalans, who were bitterly angered by the excesses of the troops sent to operate against the French in Roussillon. They called in the French, and the Spanish government was compelled to neglect Portugal. Olivares, who was denounced by the nation as the cause of all its misfortunes, was dismissed, and the king made a brief effort to rule for himself. But he soon fell back under the control of less capable favourites than Olivares. In 1643 the prestige of the Spanish infantry was ruined by the battle of Rocroy. At the peace of Münster, which ended the Thirty Years' War in 1648, Spain was cynically thrown over by the German Habsburgs for whom she had sacrificed so much. Aided by the disorders of the minority of Louis XIV., she struggled on till the peace of the Pyrenees in 1659, by which Roussillon was ceded to France. An attempt was now made to subdue Portugal, but the battle of Montesclaros in 1665 proved the futility of the effort. The news of the disaster was followed by the death of the king on the 17th of September 1665. Catalonia was saved by the reaction produced in it by the excesses of the French troops, and in Naples the revolt had collapsed. But Portugal was lost for ever, and the final judgment on the time may be passed in the words of Olivares, who complained that he could find "no men" in Spain. He meant no men fit for high command. The intellect and character of the nation had been rendered childish.

Charles II., 1665–1700.

During the whole of the reign of Charles II. (1665–1700), the son of the second marriage of Philip IV. with his niece Mariana of Austria, the Spanish monarchy was an inert mass, which Louis XIV. treated as raw material to be cut into at his discretion, and was saved from dismemberment only by the intervention of England and Holland. The wars of 1667–68, ended by the peace of Aix-la-Chapelle, those of 1672–78, ended by the peace of Nijmwegen, those of 1683–84, ended by the peace of Ratisbon, and the war of the League of Augsburg, 1689–96, were some of them fought wholly, and all of them partly, because the French king wished to obtain one or another portion of the dominions of the Spanish Habsburgs. But Spain took a subordinate and often a merely passive part in these wars. The king was imbecile. During his minority the government was directed by his mother and her successive favourites, the German Jesuit Nithard and the Granadine adventurer Fernando de Valenzuela. In 1677 the king's bastard brother, the younger Don John of Austria, defeated the queen's faction, which was entirely Austrian in sentiment, and obtained power for a short time. By him the king was married in 1679 to Marie Louise of Orleans, in the interest of France. When she died in 1689, he was married by the Austrian party to Mariana of Neuburg. At last the French party, which hoped to save their monarchy from partition by securing the support of France, persuaded the dying king to leave his kingdom by will to the duke of Anjou, the grandson of Louis XIV., and of Maria Teresa, daughter of Philip IV. by his first marriage. On the death of Charles II., on the 1st of November 1700, the duke of Anjou was proclaimed king.

The Bourbon Dynasty.—The decision of Louis XIV. to accept the inheritance left to his grandson by Charles II. led to a final struggle between him and the other powers of western Europe (see Spanish Succession, War of the), which was terminated in 1713 by the peace of Utrecht.

War of Spanish Succession, 1700–13.

The part taken by Spain in the actual struggle was mainly a passive one, and it ended for her with the loss of Gibraltar and the island of Minorca, which remained in the hands of England, and of all her dominions in Italy and Flanders. Another and a very serious consequence was that England secured the *Asiento* (*q.v.*), or contract, which gave her the monopoly of the slave trade with the Spanish colonies, as well as the right to establish "factories"—that is to say commercial agencies—in several Central and South American ports, and to send one cargo of manufactured goods yearly in a ship of 500 tons to New Carthagena. In internal affairs the years of the war were of capital importance in Spanish history.

Philip V., 1700–1746.

The general political and administrative nullity of the Spaniards of this generation led to the assumption of all real power by the French or Italian servants and advisers of the king. Under their direction important financial and administrative reforms were begun. The opposition which these innovations produced encouraged the separatist tendencies of the eastern portion of the Peninsula. Philip V. was forced to reduce Aragon, Catalonia and Valencia by arms. Barcelona was only taken in 1714, the year after the signing of the treaty of Utrecht. The local privileges of these once independent kingdoms, which had with rare exceptions been respected by the Austrian kings, were swept away. Their disappearance greatly promoted the work of national unification, and was a gain, since they had long ceased to serve any really useful purpose. The removal of internal custom-houses, and the opening of the trade with America, hitherto confined to Seville and to the dominions of the crown of Castile, to all Spaniards, were considerable boons. The main agents in introducing and promoting these changes were the French ambassadors, a very able French treasury official—Jean Orry, seigneur de Vignory (1652–1719)—and the lady known as the princess des Ursins (*q.v.*), the chief lady-in-waiting. Her maiden name was Anne Marie de la Trémoille, and she was the widow of Flavio Orsini, duke of Bracciano. Until 1714 she was the power behind the throne in Spain. On the death of Philip V.'s first wife Maria Louisa Gabriella of Savoy, in 1714, the king was married at once to Elizabeth Farnese of Parma, who expelled Mme des Ursins, obtained complete control over her husband, and used her whole influence to drag Spain into a series of adventures in order to obtain Italian dominions for her sons.

Queen Elizabeth Farnese and Alberoni.

Her first agent was the Italian priest Alberoni (*q.v.*), whose favour lasted from 1714 to 1719. Alberoni could not, and perhaps did not, sincerely wish to prevent the queen and king from plunging into an attempt to recover Sardinia and Sicily, which provoked the armed intervention of France and England and led to the destruction of the rising Spanish navy off Cape Pássaro (see Torrington, George Byng, Viscount). In 1731 Elizabeth secured the succession of her eldest son, Charles, afterwards Charles III. of Spain, to the duchy of Parma, by arrangement with England and the Empire. Apart from the Italian intrigues, the most important foreign affairs of the reign were connected with the relations of Spain with England. A feeble attempt to regain

Gibraltar was made in 1733, and a serious war was only averted by the resolute peace policy of Sir Robert Walpole. But in 1739 trade difficulties, which had arisen out of the *Asiento* in America, led to a great war with England, which became merged in the War of the Austrian Succession (*q.v.*). The king, who had become almost entirely mad at the end of his life, died on the 9th of July 1746. His successor, Ferdinand VI., the second son of his first marriage, whose reign lasted till the 10th of August 1759, was a retiring and modest man, who adopted a policy of peace with England.

Ferdinand VI., 1746–1759.

His ministers, of whom the most notable were Zenon de Somadevila, marquis of Ensenada, and Richard Wall, an Irish Jacobite, carried on the work of financial and administrative reform. The advance of the country in material prosperity was considerable. Foreign influences in thought and literature began to modify the opinions of Spaniards profoundly. The party known as the *Regalistas*, the lawyers who wished to vindicate the regalities, or rights of the Crown, against the encroachments of the pope and the Inquisition, gained the upper hand.

The new sovereign was one of the most sincere, and the most successful, of the "enlightened despots" of the 18th century.

Charles III., 1759–1788.

He had had a long apprenticeship in Naples, and was a man of forty-three when he came to Spain in 1759. Until his death on the 14th of December 1788 he was engaged in internal politics, in endeavouring to advance the material prosperity of Spain. His foreign policy was less wise. He had a deep dislike of England, and a strong desire to recover Minorca and Gibraltar, which she held. He had also a strong family feeling, which induced him to enter into the "Family Compact" with his French cousins. He made war on England in 1761, with disastrous results to Spain, which for the time lost both Havana and Manila. In 1770 he came to the verge of war with England over the Falkland Islands. In 1778 he joined France in supporting the insurgent English colonists in America. The most statesmanlike of his foreign enterprises, the attempt to take the piratical city of Algiers in 1775 (see Barbary Pirates), was made with insufficient forces, was ill executed, and ended in defeat. Yet he was able to recover Minorca and Florida in the War of American Independence, and he finally extorted a treaty with Algiers which put a stop to piratical raids on the Spanish coast. The worst result for Spain of his foreign policy was that the example set by the United States excited a desire for independence in the Spanish colonies, and was the direct incitement to the rebellions at the beginning of the 19th century. The king's domestic policy, on the contrary, was almost wholly fruitful of good. Under his direction many useful public works were carried out—roads, bridges and large schemes of drainage. The first reforms undertaken had provoked a disturbance in Madrid directed against the king's favourite minister, the Sicilian marquis of Squillacci. Charles, who believed that the Jesuits had promoted the outbreak, and also that they had organized a murder plot against him, allowed his minister Aranda (*q.v.*), the correspondent of Voltaire, to expel the order in 1766, and he exerted his whole influence to secure its entire suppression. The new spirit was otherwise shown by the restrictions imposed on the numbers of the religious orders and on the Inquisition, which was reduced to practical subjection to the lay courts of law. Many of the king's industrial enterprises, such as the Bavarian colony, established by him on the southern slope of the Sierra Morena, passed away without leaving much trace. On the other hand the shipping and the industry of Spain increased greatly. The population made a considerable advance, and the dense cloud of sloth and ignorance which had settled on the country in the 17th century was lifted. In this work Charles III. was assisted, in addition to Squillacci and Aranda, by Campomanes (*q.v.*), who succeeded Aranda as minister of finance in 1787, and by Floridablanca (*q.v.*), who ruled the country in the spirit of enlightened bureaucracy.

Charles III. was succeeded in 1788 by his son Charles IV. The father, though "enlightened," had been a thorough despot; the son was sluggish and stupid to the verge of imbecility, but the despotism remained. The new king was much under the influence of his wife, Maria Louisa of Parma, a coarse, passionate and narrow-minded woman; but he continued to repose confidence in his father's ministers.

Charles IV., 1788–1808.

Floridablanca was, however, unable to continue his earlier policy, in view of the contemporaneous outbreak of the Revolution in France. The revival of Spain depended on the restoration of her colonial and naval ascendancy at the expense of Great Britain, and for this the support of France was needed. But the "Family Compact," on which the French alliance depended, ceased to exist when Louis XVI. was deprived of power by his subjects. Of this conclusive evidence was given in 1791. Some English merchants had violated the shadowy claim of Spain to the whole west coast of America by founding a settlement at Nootka Sound. The Spanish government lodged a vigorous protest, but the French National Assembly refused to lend any assistance, and Floridablanca was forced to conclude a humiliating treaty and give up all hope of opposing the progress of Great Britain. This failure was attributed by the minister to the Revolution, of which he became the uncompromising opponent.

Spain and the French Revolution.

The reforms of Charles III.'s reign were abandoned and all liberal tendencies in Spain were suppressed. But Floridablanca was not content with suppressing liberalism in Spain; he was eager to avenge his disappointment by crushing the Revolution in France. He opened negotiations with the *émigrés*, urged the European powers to a crusade on behalf of legitimacy, and paraded the devotion of Charles IV. to the head of his family. This bellicose policy, however, brought him into collision with the queen, who feared that the outbreak of war would diminish the revenues which she squandered in self-indulgence. She had already removed from the ministry Campomanes and other supporters of Floridablanca, and had compelled the latter to restrict himself to the single department of foreign affairs. Early in 1792 she completed her task by inducing Charles IV. to banish Floridablanca to Murcia, and his place was entrusted to the veteran Aranda, who speedily found that he held office only by favour of the queen, and that this had to be purchased by a disgraceful servility to her paramour, Emanuel Godoy. Spain withdrew from the projected coalition against France, and sought to maintain an attitude of neutrality, which alienated the other powers, while it failed to conciliate the Republic. The repressive measures of Floridablanca were withdrawn; society and the press regained their freedom; and no opposition was offered to the propaganda of French ideas. Aranda's policy might have been successful if it had been adopted earlier, but the time for temporizing was now past, and it was necessary to choose one side or the other. In November 1792 the queen felt herself strong enough to carry out the scheme which she had been long maturing. Aranda was dismissed, and the office of first minister was entrusted to Godoy, who had recently received the title of duke of Alcudia.

Godoy.

Godoy, who was at once the queen's lover and the personal favourite of the king, had no experience of the routine of office, and no settled policy. Fortunately for him, the course now to be pursued was decided for him. The execution of Louis XVI. (Jan. 21, 1793) made a profound impression in a country where loyalty was a superstition. Charles IV. was roused to demand vengeance for the insult to his family, and Spain became an enthusiastic member of the first coalition against France. The number of volunteers who offered their services rendered conscription unnecessary; and the southern provinces of France welcomed the Spaniards as deliverers. These advantages, however, were nullified by the shameful incompetence and carelessness of the government. The troops were left without supplies; no plan of combined action was imposed upon the commanders; and the two campaigns of 1793 and 1794 were one long catalogue of failures. Instead of reducing the southern provinces of France, the Spaniards were driven from the strong fortresses that guarded the Pyrenees, and the French advanced almost to the Ebro; and at the same time the British were utilizing the war to extend their colonial power and were establishing more firmly that maritime supremacy which the Spanish government had been struggling for almost a century to overthrow. Under the circumstances the queen and Godoy hastened to follow the example set by Prussia, and concluded the treaty of Basel with France (1795). The terms were unexpectedly favourable, and so great was the joy excited in Madrid that popular acclamation greeted the bestowal upon Godoy of the title of "Prince of the Peace." But the moderation of the treaty was only a flimsy disguise of the disgrace that it involved. Spain found herself tied hand and foot to the French republic. Godoy had to satisfy his allies by the encouragement of reforms which both he and his mistress loathed, and in 1796 the veil was removed by the conclusion of the treaty of San Ildefonso. This was a virtual renewal of the "Family Compact" of 1761, but with terms far more disadvantageous to Spain. Each power was pledged to assist the other in case of war with twenty-five ships, 18,000 infantry and 6000 cavalry. The real object of the treaty, which was to involve Spain in the war against Great Britain, was cynically avowed in the 18th article, by which, during the present war, the Spanish obligations were only to apply to the quarrel between Great Britain and France. A scheme was prepared for a joint attack on the English coast, but it was foiled by the battle of St Vincent (*q.v.*), in which Jervis and Nelson forced the Spanish fleet to retire to Cadiz. This defeat was the more disastrous because it deprived Spain of the revenues derived from her colonies. Great Britain seized the opportunity to punish Spain for its conduct in the American War by encouraging discontent in the Spanish colonies, and in the Peninsula itself both nobles and people were bitterly hostile to the queen and her favourite. It was in vain that Godoy sought to secure the friendship of the reforming party by giving office to two of its most prominent members, Jovellanos and Saavedra. Spanish pride and bigotry were offended by the French occupation of Rome and the erection of a republic in the place of the papal government. The treatment of the duke of Parma by the Directory was keenly resented by the queen. Godoy found himself between two parties, the Liberals and the Ultramontanes, who agreed only in hatred of himself. At the same time the Directory, whose mistrust was excited by his attitude in the question of Parma, insisted upon his dismissal. Charles IV. could not venture to refuse; the queen was alienated by Godoy's notorious infidelities; and in March 1798 he was compelled to resign his office.

Godoy's office was entrusted to Saavedra, but the reformers did not obtain the advantages which they expected from the change. Jovellanos was compelled in August to retire on account of ill health—the result, it was rumoured—of attempts on the part of his opponents to poison him. His place was taken by Caballero, an ardent opponent of reform, who restored all the abuses of the old bureaucratic administration and pandered to the bigoted prejudices of the clergy and the court. The only advantage which Spain enjoyed at this period was comparative independence of France. The military plans of the Directory were unsuccessful during the absence of their greatest general in Egypt, and the second coalition gained successes in 1799 which had seemed impossible since 1793. But the return of Bonaparte, followed as it was by the fall of the Directory and the establishment of the Consulate, commenced a new epoch for Spain. As soon as the First Consul had time to turn his attention to the Peninsula, he determined to restore Godoy, who had already regained the affection of the queen, and to make him the tool of his policy. Maria Louisa was easily gained over by playing on her devotion to the house of Parma, and on the 1st of October 1800 a secret treaty was concluded at San Ildefonso. Spain undertook to cede Louisiana and to aid France in all her wars, while Bonaparte promised to raise the duke of Parma to the rank of king and to increase his territories by the addition either of Tuscany or of the Roman legations. This was followed by Godoy's return to power, though he left the department of foreign affairs to a subordinate. Spain was now more servile to France than ever, and in 1801 was compelled to attack Portugal in the French interests. The Spanish invasion, commanded by Godoy in person, met with no resistance, and the prince ventured to conclude a peace on his own authority by which Portugal promised to observe a strict neutrality on condition that its territories were left undiminished. But Bonaparte resented this show of independence, and compelled Charles IV. to refuse his ratification of the treaty. Portugal had to submit to far harsher terms, and could only purchase peace by the cession of territory in Guiana, by a disadvantageous treaty of commerce, and by payment of twenty-five million francs. In the preliminary treaty with Great Britain he ceded the Spanish colony of Trinidad without even consulting the court of Madrid, while he sold Louisiana to the United States in spite of his promise not to alienate it except to Spain.

Napoleon and Spain.

Godoy, since his return, had abandoned all connexion with the reforming party. The Spanish Church was once more placed in strict subjection to the Roman see, from which for a short time it had been freed. As soon as Bonaparte saw himself involved in a new war with England, he turned to Spain for assistance and extorted a new treaty (Oct. 9, 1803), which was still more burdensome than that of 1796. Spain had to pay a monthly subsidy of six million francs, and to enforce strict neutrality upon Portugal, this involving war with England. The last remnants of its maritime power were shattered in the battles of Cape Finisterre and Trafalgar, and the English seized Buenos Aires. The popular hatred of Godoy was roused to passion by these disasters, and Spain seemed to stand on the brink of revolution. At the head of the opposition was Ferdinand, the heir to the throne, as insignificant as his rival, but endowed with all good qualities by the credulous favour of the people. Napoleon was at this time eager to humble Great Britain by excluding it from all trade with Europe. The only country which had not accepted his "continental system" was Portugal, and he determined to reduce that kingdom by force. It was not difficult to bribe Godoy, who was conscious that his position could not be maintained after the death of Charles IV. In October 1807 Spain accepted the treaty of Fontainebleau. (See PORTUGAL: *History*.) The treaty was hardly concluded when a French army under Junot marched through Spain to Portugal, and the royal family of that country fled to Brazil. Ferdinand, whose wife had died in 1806, determined to imitate his rival by bidding for French support. He entered into secret relations with Eugène Beauharnais, Napoleon's envoy at Madrid, and went so far as to demand the hand of a Bonaparte princess. Godoy, who discovered the intrigue, induced Charles IV. to order his son's arrest (Oct. 27, 1807), on the charge of plotting to dethrone his father and to murder his mother and Godoy. The prince indeed was soon released and solemnly pardoned; but, meanwhile, Napoleon had seized the opportunity afforded by the effect of this public scandal in lowering the prestige of the royal family to pour his troops into Spain, under pretext of reinforcing Junot's corps in Portugal. Even this excuse was soon dropped, and by January and February 1808 the French invasion had become clearly revealed as one of conquest. Charles IV. and his minister determined on flight. The news of this intention, however, excited a popular rising at Aranjuez, whither the king and queen had gone from Madrid. A raging mob surrounded the palace, clamouring for Godoy's head; and the favourite's life was only saved by Charles IV.'s announcement of his abdication in favour of Ferdinand (March 17). Murat, however, who commanded the French, refused to be turned aside by this change of circumstances. He obtained from Charles IV. a declaration that his abdication had been involuntary, and occupied Madrid (March 23, 1808). Meanwhile Napoleon had advanced to Bayonne on the frontier, whither, at his orders, Murat despatched the old king and queen and their favourite Godoy. The emperor had already made up his mind to place one of his brothers on the Spanish throne; but in order to achieve this it was necessary to cajole the young king Ferdinand VII. and get him into his power. Ferdinand, instead of retiring to Andalusia and making himself the rallying point of national resistance, had gone to Madrid, where he was at the mercy of Murat's troops and whence he wrote grovelling letters to Napoleon. It was no difficult matter for the emperor's

Napoleon attacks Spain.

envoy, General Savary, to lure him by specious promises to the frontier, and across it to Bayonne, where he was confronted with his parents and Godoy in a scene of pitiful degradation. Struck and otherwise insulted, he was forced to restore the crown to his father, who laid it at the feet of Napoleon. The old king and queen, pensioned by the French government, retired to Rome; Ferdinand was kept for six years under strict military guard at Talleyrand's château of Valençay (see FERDINAND VII., King of Spain). On the 13th of May Murat announced to an improvised "junta of regency" at Madrid that Napoleon desired them to accept Joseph Bonaparte as their king.

Abdication of Charles IV.

Joseph Bonaparte proclaimed King.

But Spanish loyalty was too profound to be daunted even by the awe-inspiring power of the French emperor. For the first time Napoleon found himself confronted, not by terrified and selfish rulers, but by an infuriated people. The rising in Spain began the popular movement which ultimately proved fatal to his power. At first he treated the novel phenomenon with contempt, and thought it sufficient to send his less prominent generals against the rebels. Madrid was easily taken, but the Spaniards showed great capacity for the guerrilla warfare in the provinces. The French were repulsed from Valencia; and Dupont, who had advanced into the heart of Andalusia, was compelled to retreat and ultimately to capitulate with all his forces at Baylen (July 10). The Spaniards now advanced upon Madrid and drove Joseph from the capital, which he had just entered. Unfortunately the insurgents displayed less political ability than military courage. Godoy's agents, the ministers, were swept aside by the popular revolt, and their place was taken by local *juntas*, or committees, and then by a central junta formed from among them, which ruled despotically in the name of the captive king. In a country divided by sectional jealousies it was impossible to expect a committee of thirty-four members to impose unity of action even in a common cause; and the Spanish rising, the first fierceness of which had carried all before it, lacked the organizing force which alone would have given it permanent success. As it was, Napoleon's arrival in Spain was enough to restore victory to the French. In less than a week the Spanish army was broken through and scattered, and Napoleon restored his brother in Madrid. Sir John Moore, who had advanced with an English army to the relief of the capital, retired when he found he was too late, and an obstinate battle, in which the gallant general lost his life, had to be fought before the troops could secure their embarcation at Corunna. Napoleon, thinking the work accomplished, had quitted the Peninsula, and Soult and Victor were left to complete the reduction of the provinces. The capture of Seville resulted in the dissolution of the central junta, and the Peninsula was only saved from final submission by the obstinate resistance of Wellington in Portugal and by dissensions among the French. The marshals were jealous of each other, and Napoleon's plans were not approved by his brother. Joseph wished to restore peace and order among his subjects in the hope of ruling an independent nation, while Napoleon was determined to annex Spain to his own overgrown empire. So far did these disputes go that Joseph resigned his crown, and was with difficulty induced to resume it. Meanwhile, the dissolution of the central junta had given free play to the extremer reforming parties; on the 24th of September these met at Cadiz, which became the capital of what was left of independent Spain.

Cortes of 1810.

The Spanish Cortes had never been so entirely suspended as the states-general of France. Philip V., after suppressing the local institutions of the crown of Aragon, had given representation to some of the eastern cities in the general Cortes of Spain. This body had been summoned at the beginning of reigns to swear homage to the new king and his heir, or to confirm regulations made as to the succession. It sat in one house, and was composed of the nobles and churchmen who formed the great majority of procurators chosen by the town councils of a limited though varying number of towns, and of representatives of "kingdoms." The Cortes of 1810 was constructed on these lines, but with a very important difference in the proportion of its elements. The third estate of the commons secured 184 representatives, who were sufficient to swamp the nobles and the clergy. No intelligent scheme under which the representatives were to be elected had been fixed. In theory the members of the third estate had been chosen by a process of double election. In fact, however, since much of the country was held by the French, they were often returned by such natives of the regions so occupied as happened to be present in Cadiz at the time. The real power fell to those of the delegates who were influenced by the new ideas. Unhappily, they had no experience of affairs; and they were perfectly ready to make a constitution for Spain on Jacobin lines, without the slightest regard to the real beliefs and interests of Spaniards. Out of these mateiials nothing could be expected to come except such a democratic constitution as might have been made by a Jacobin club in Paris. In a country noted for its fanatical loyalty to the Crown and the Church, the kingship was to be deprived of all power and influence, and the clergy to be excluded as such from all share in legislation. As though to deprive the constitution of any chance of being made effective, the worst expedients dictated by the suspicious temper of the French convention of 1790 were adopted. Ministers were excluded from the chamber, thus rendering impossible any effective co-operation between the legislature and the executive; and, worst of all, a provision was introduced making members of the Cortes ineligible for re-election, an effective bar to the creation of a class of politicians possessing experience of affairs.

Spanish Constitution of 1812.

The Spaniards were so broken to obedience, and the manlier part of them so intent on fighting the French, that the Cortes was not at the time resisted. The suppression of the Inquisition and the secularization of the church lands—measures which had already been taken by the government of the intruding French king Joseph at Madrid—passed together with much else. But even before the new constitution was published and sworn, on the 19th of March 1812, large numbers of Spaniards had made up their minds that after the invaders were driven out the Cortes must be suppressed.

The liberation of Spain could hardly have been accomplished without the assistance of Great Britain. The story of the struggle, from the military point of view, is told in the article PENINSULAR WAR. In 1812 Wellington determined on a great effort. He secured his base of operations by the capture of Ciudad Rodrigo and Badajoz, and at Salamanca he completely routed the opposing army of Marmont. This victory enabled the English general to enter Madrid (Aug. 12), and Joseph retreated to Valencia. But further advance was prevented by the concentration of the French forces in the east, and Wellington found it advisable to retire for the third time to winter quarters on the Portuguese frontier. It was during this winter that Napoleon suffered his first and greatest reverse in the retreat from Moscow and the destruction of his grand army. This was the signal for the outbreak of the "war of liberation" in Germany, and French troops had to be withdrawn from Spain to central Europe. For the first time Wellington found himself opposed by fairly equal forces. In the spring of 1813 he advanced from Ciudad Rodrigo and defeated Jourdan at Vittoria, the battle which finally decided the Peninsular War. Joseph retired altogether from his kingdom, and Wellington, eager to take his part in the great European contest, fought his way through the Pyrenees into France. Napoleon, who had suffered a crushing defeat at Leipzig, hastened to recognize the impossibility of retaining Spain by releasing Ferdinand VII., who returned to Madrid in March 1814.

Restoration of Ferdinand VII., 1814.

Before entering Spain Ferdinand had undertaken to maintain the constitution of 1812, and when on the 22nd of March 1814 he reached Figueras, he was met by a demand on the part of the Cortes that he must accept all the terms of the constitution as a condition of his recognition as king. But Ferdinand had convincing proof of the true temper of the nation. He now refused to recognize the constitution, and was supported in his refusal not only by the army and the Church, but by the masses. There can be no doubt that Ferdinand VII. could have ruled despotically if he had been able to govern well. But, although possessed of some sardonic humour and a large measure of cunning, he was base, and had no real capacity. He changed his ministers incessantly, and on mere caprice. Governed by a *camarilla* of low favourites, he was by nature cruel as well as cowardly. The government under him was thoroughly bad, and the persecution of the "Jacobins," that is of all those suspected of Liberal sentiment, ferocious. Partial revolts took place, but were easily crushed. The revolt which overpowered him in 1820 was a military mutiny. During the war the American colonies had rebelled, and soldiers had been sent to suppress them. No progress had been made, the service was dreadfully costly in life, and it became intensely unpopular among the troops. Meanwhile the brutality of the king and his ministers had begun to produce a reaction. Not a few of the officers held Liberal opinions, and this was especially the case with those who had been prisoners in France during the war and had been inoculated with foreign doctrines.

Revolution of 1820.

These men, of whom the most conspicuous was Colonel Rafael Riego (*q.v.*), worked on the discontent of the soldiers, and in January 1820 brought about a mutiny at Cadiz, which became a revolution. Until 1823 the king was a prisoner in the hands of a section of his subjects, who restored the constitution of 1812 and had the support of the army. The history of these three miserable years cannot be told except at impossible length. It was a mere anarchy. The Liberals were divided into sub-sections, distinguished from one another by a rising scale of violence. Any sign of moderation on the part of the ministers chosen from one of them was enough to secure him the name of "Servile" from the others. The "Serviles" proper took up arms in the north. At last this state of affairs became intolerable to the French government of Louis XVIII. As early as 1820 the emperor Alexander I. of Russia had suggested a joint intervention of the powers of the Grand Alliance to restore order in the Peninsula, and had offered to place his own army at their disposal for the purpose.

The Congress of Verona and Spain.

The project had come to nothing owing to the opposition of the British government and the strenuous objection of Prince Metternich to a course which would have involved the march of a powerful Russian force through the Austrian dominions. In 1822 the question was again raised as the main subject of discussion at the congress assembled at Verona (see VERONA, CONGRESS OF). The French government now asked to be allowed to march into Spain, as Austria had marched into Naples, as the mandatory of the powers, for the purpose of putting a stop to a state of things perilous alike to herself and to all Europe. In spite of the vigorous protest of Great Britain, which saw in this demand only a pretext for reviving the traditional Bourbon ambitions in the Peninsula, the mandate was granted by the majority of the powers; and on the 7th of April 1823 the duke of Angoulême, at the head of a powerful army, crossed the Bidassoa.

French Intervention, 1823.

The result was a startling proof of the flimsy structure of Spanish Liberalism. What the genius of Napoleon had failed to accomplish through years of titanic effort, Angoulême seemed to have achieved in a few weeks. But the difference of their task was fundamental. Napoleon had sought to impose upon Spain an alien dynasty; Angoulême came to restore the Spanish king "to his own." The power of Napoleon had been wrecked on the resistance of the Spanish people; Angoulême had the active support of some Spaniards and the tacit co-operation of the majority. The Cortes, carrying the king with it, fled to Cadiz, and after a siege, surrendered with no conditions save that of an amnesty, to which Ferdinand solemnly swore before he was sent over into the French lines. As was to be expected, an oath taken "under compulsion" by such a man was little binding; and the French troops were compelled to witness, with helpless indignation, the orgy of cruel reaction which immediately began under the protection of their bayonets.

The events of the three years from 1820–1823 were the beginning of a series of convulsions which lasted till 1874. On the one hand were the Spaniards who desired to assimilate their country to western Europe, and on the other those of them who adhered to the old order. The first won because the general trend of the world was in their favour, and because their opponents were blind, contumacious, and divided among themselves.

The Spanish Colonies.

If anything could have recalled the distracted country to harmony and order, it would have been the object-lesson presented by the loss of all its colonies on the continent of America. These had already become *de facto* independent during the death-struggle of the Spanish monarchy with Napoleon, and the recognition of their independence *de jure* was, for Great Britain at least, merely a question of time. A lively trade had grown up between Great Britain and the revolted colonies; but since this commerce, under the colonial laws of Spain, was technically illegitimate, it was at the mercy of the pirates, who preyed upon it under the aegis of the Spanish flag, without there being any possibility of claiming redress from the Spanish government. The decision of the powers at the congress of Verona to give a free hand to France in the matter of intervention in Spain, gave the British government its opportunity. When the invasion of Spain was seen to be inevitable, Canning had informed the French government that Great Britain would not tolerate the subjugation of the Spanish colonies by foreign force. A disposition of the powers of the Grand Alliance to come to the aid of Spain in this matter was countered by the famous message of President Monroe (Dec. 2, 1823), laying the veto of the United States on any interference of concerted Europe in the affairs of the American continent. The empire of Brazil and the republics of Mexico and Colombia were recognized by Great Britain in the following year; the recognition of the other states was only postponed until they should have given proof of their stability. In announcing these facts to the House of Commons, George Canning, in a phrase that became famous, declared that he had "called a new world into existence to redress the balance of the old" and that "if France had Spain, it should at least be Spain without her colonies."

Reactionary Elements in Spain.

In Spain itself, tutored by misfortune, the efforts of the king's ministers, in the latter part of his reign, were directed to restoring order in the finances and reviving agriculture and industry in the country. The king's chief difficulties lay in the attitude of the extreme monarchists (*Apostolicos*), who found leaders in the king's brother Don Carlos and his wife Maria Francisca of Braganza. Any tendency to listen to liberal counsels was denounced by them as weakness and met by demands for the restoration of the Inquisition and by the organization of absolutist demonstrations, and even revolts, such as that which broke out in Catalonia in 1828, organized by the "supreme junta" set up at Manresa, with the object of freeing the king from "the disguised Liberals who swayed him." Yet the absolute monarchy would probably have lasted for long if a dispute as to the succession had not thrown one of the monarchical parties on the support of the Liberals.

Question of the Succession. The Pragmatic Sanction.

The king had no surviving children by his first three marriages. By his fourth marriage, on the 11th of December 1829, with Maria Christina of Naples he had two daughters. According to the ancient law of Castile and Leon women could rule in their own right, as is shown by the examples of Urraca, Berengaria, and Isabella the Catholic. In Aragon they could transmit the right to a husband or son. Philip V. had introduced the Salic Law, which confined the succession to males. But his law had been revoked in the Cortes summoned in 1789 by Charles IV. The revocation had not however been promulgated. Under the influence of Maria Christina Ferdinand VII. formally promulgated it at the close of his life, after some hesitation, and amid many intrigues.

Isabella II., Queen, 1833.

When he died on the 29th of September 1833, his daughter Isabella II. was proclaimed queen, with her mother Maria Christina as regent.

The immediate result of the dead king's decision was to throw Spain back into a period of squalid anarchy. Maria Christina would have ruled despotically if she could, and began by announcing that material changes would not be made in the method of government. But the Conservatives preferred to support the late king's brother Don Carlos, and they had the active aid of the Basques, who feared for their local franchises, and of the mountaineers of Navarre, Aragon, Catalonia and Valencia, who were either quite clerical, or who had become attached, during the French invasion and the troubles of the reign of Ferdinand, to a life of *guerrillero* adventure. Maria Christina had the support of the army, and the control of the machinery of government; while the mass of the people passively submitted to the powers that were, while as far as possible eluding their orders. The regent soon found that this was not enough to enable her to resist the active hostility of the Carlists and the intrigues of their clerical allies. She was eventually driven by the necessities of her position to submit to the establishment of parliamentary institutions. She advanced only when forced, first by the need for buying support, and then with the bayonet at her back. First the historic Cortes was summoned. Then in April 1834, under the influence of the minister Martinez de La Rosa, a charter (*Estatudo Real*) was issued establishing a Cortes in two *Estamentos* or Estates, one of senators (*próceres*) and one of deputies, but with no rights save that of petition, and absolutely dependent on the Crown. This constitution was far from satisfying the advanced Liberals, and the supporters of Christina—known as *Cristinos*—broke into two sections, the *Moderados*, or Moderates, and *Progressistas* or *Exaltados*, the Progressists or Hot-heads. In August 1836 a military revolt at the palace of La Granja in the hills above Segovia drove the regent by sheer violence to accept a democratic constitution, based on that of 1812, which was issued in 1837. Meanwhile Cristinos and Carlistas, the successors of the "Liberales" and "Serviles," were fighting out their quarrel. In 1835 a violent outbreak against the monastic orders took place. In some cities, notably in Barcelona, it was accompanied by cruel massacres. Though the measure was in itself repugnant to Maria Christina, the pressing needs of her government compelled her to consent when Juan Alvarez y Mendizabal (1790–1853), a minister of Jewish descent, forced on her by Liberals, secularized the monastic lands and used them for a financial operation which brought some relief to the treasury.

Regency of Christina.

Constitution of 1837.

The Carlist War lasted from the beginning of Isabella's reign till 1840. At first the Carlists were feeble, but they gathered strength during the disputes among the Cristinos. Their leaders, Tomas Zumalacarregui in Biscay and Navarre, and Ramon Cabrera in Valencia, were the ablest Spaniards of their time. The war was essentially a *guerrilleros* struggle in which the mountaineers held their ground among the hills against the insufficient, ill-appointed, and mostly very ill-led armies of the government, but were unable to take the fortresses, or to establish themselves in central Spain south of the Ebro; though they made raids as far as Andalusia. At last, in August 1839, exhaustion brought the Basques to recognize the government of Queen Isabella by the convention of Vergara in return for the confirmation of their privileges. The government was then able to expel Cabrera from Valencia and Catalonia. Great Britain and France gave some help to the young queen, and their intervention availed to bring a degree of humanity into the struggle.

The Carlist War.

Maria Christina, who detested the parliamentary institutions which she had been forced to accept, was always ready to nullify them by intrigue, and she was helped by the *Moderados*. In 1841 the regent and the *Moderados* made a law which deprived the towns of the right of electing their councils. It was resented by the Liberals and provoked a military rising, headed by the most popular of the Cristino generals, Baldomero Espartero. The queen regent having been compelled to sign a decree illegally revoking the law, resigned and left for France. Espartero was declared regent. He held office till 1843, during an agitated period, in which the Carlists reappeared in the north, mutinies were common, and a barbarous attempt was made to kidnap the young queen in her palace on the night of the 7th of October 1841. It was only defeated by the hard fighting of eighteen of the palace guards at the head of the main staircase. In 1843 Espartero, a man of much personal courage and of fitful energy, but of no political capacity, was expelled by a military rising, promoted by a combination of discontented Liberals and the Moderates. The queen, though only thirteen years old, was declared of age.

Revolt and Regency of Espartero.

The reign of Queen Isabella, from 1843 till her expulsion in 1868, was a prolongation of that of her mother's regency. It was a confused conflict between the constant attempt of the court to rule despotically, with a mere pretence of a Cortes, and the growing wish of the Spaniards to possess a parliamentary government, or at least the honest and capable government which they hoped that a parliament would give them. In 1845 the Moderates having deceived their Liberal allies, revised the constitution of 1837 and limited the freedom it gave. Their chief leader, General Ramon Narvaez, had for his guiding principle that government must be conducted by the stick and by hard hitting. In 1846 Europe was scandalized by the ignominious intrigues connected with the young queen's marriage. Louis Philippe, king of the French, saw in the marriage of the young queen a chance of reviving the family alliance which had, in the 18th century, bound Bourbon Spain to Bourbon France. The court of Madrid was rent by the intrigues of the French and the English factions; the former planning an alliance with a son of the French king, the latter favouring a prince of the house of Coburg. The episode of the Spanish marriages forms an important incident in the history of Europe; for it broke the *entente cordiale* between the two western Liberal powers and accelerated the downfall of the July monarchy in France. There can be no doubt, in spite of the apology for his action published by Guizot in his memoirs, that Louis Philippe made a deliberate attempt to overreach the British government; and, if the attempt issued in disaster to himself, this was due, not to the failure of his statecraft so much as to his neglect of the obvious factor of human nature. Palmerston, on behalf of Great Britain, had agreed to the principle that the queen should be married to one of her Bourbon cousins of the Spanish line, and that the younger sister should marry the duke of Montpensier, son of Louis Philippe, but not till the birth of an heir to the throne should have obviated the danger of a French prince wearing the crown of Spain. Louis Philippe, with the aid of the queen-mother, succeeded in forcing Isabella to accept the hand of Don Francisco d'Assisi, her cousin, who was notoriously incapable of having heirs; and on the same day the younger sister was married to the duke of Montpensier. The queen's marriage was miserable; and she consoled herself in a way which at once made her court the scandal of Europe, and upset the French king's plans by providing the throne of Spain with healthy heirs of genuine Spanish blood. But incidentally the scandals of the palace had a large and unsavoury part in the political troubles of Spain. Narvaez brought Spain through the troubled revolutionary years 1848 and 1849 without serious disturbance, but his own unstable temper, the incessant intrigues of the palace, and the inability of the Spaniards to form lasting political parties made good government impossible. The leaders on all sides were of small capacity. In 1854 another series of outbreaks began which almost ended in a revolution. Liberals and discontented Moderates, supported as usual by troops led into mutiny by officers whose chief object was promotion, imposed some restraint on the queen. Another revision of the constitution was undertaken, though not carried out, and Espartero was brought from retirement to head a new government. But the coalition soon broke up. Espartero was overthrown by General Leopold O'Donnell, who in 1858 formed the Union-Liberal ministry which did at last give Spain

Rule of Isabella II.

The "Spanish Marriages."

Ministry of O'Donnell.

five years of fairly good government. A successful war in Morocco in 1859 flattered the pride of the Spaniards, and the country began to make real progress towards prosperity. In 1863 the old scene of confusion was renewed. O'Donnell was dismissed. For the next five years the political history of Spain was the story of a blind attempt on the part of the queen to rule despotically, by the help of reckless adventurers of mean capacity, and by brute violence. The opposition took the form of successive military outbreaks accompanied by murder, and suppressed by massacre. In 1868 the government of Queen Isabella collapsed by its own rottenness. She had even lost the mob popularity which she had once gained by her jovial manners. All men of political influence were either in open opposition or, when they belonged to the Conservative parties, were holding aloof in disgust at the predominance of the queen's favourites, Gonzales Brabo, a mere ruffian, and Marfori, her steward, whose position in the palace was perfectly well known.

Misrule of Isabella.

In September 1868 the squadron at Cadiz under the command of Admiral Topete mutinied, and its action was the signal for a general secession. One gallant fight was made for the queen at the bridge of Alcolea in Andalusia by General Pavia, who was horribly wounded, but it was an exception. Gonzales Brabo deserted her in a panic. She went into exile, and her reign ended. The Revolution of 1868 was the first openly and avowedly directed against the dynasty. It became a familiar saying that the "spurious race of Bourbon" had disappeared for ever, and the country was called upon to make a new and a better government. But the history of the six years from September 1868 to December 1874 proved that the political incapacity of the Spaniards had not been cured. There was no definite idea anywhere as to how a substitute was to be found. A Republican party had been formed led by a few professors and coffee-house politicians, with the mob of the towns for its support, and having as its mouthpiece Don Emilio Castelar, an honest man of incredible fluency. The mass of the Spaniards, however, were not prepared for a republic. Besides them were the various monarchical parties: the *Alfonsistas*, who wished for the restoration of the queen's son with a regency, the partisans of the widower king consort of Portugal; those of the duke of Montpensier; the Carlists; and a few purely fantastic dreamers who would have given the crown to the aged Espartero. The real power was in the hands of the military politicians, Francisco Serrano (*q.v.*) and Juan Prim (*q. v.*), who kept order by means of the army. A constituent Cortes was assembled in 1869, and decided in favour of a monarchy. Serrano was declared regent until a king could be found, and it proved no easy task to find one. Ferdinand of Portugal declined. Montpensier was supposed to be unwelcome to Napoleon, and was opposed by Prim, who had also committed himself to the prophecy that the Bourbons would never return to Spain. Attempts to find a candidate in the Italian family failed at first. So did the first steps taken to find a king in the house of Hohenzollern-Sigmaringen. When the desired ruler was again sought in this family in 1870, the acceptance of the offer by Prince Leopold proved the immediate cause of the Franco-German War, in which Spain had a narrow escape of being entangled. At last, in August of 1870, Prince Amadeo of Savoy, second son of Victor Emmanuel II., consented to become candidate. He was elected on the 3rd of November. On the 27th of December 1870, on the very day on which the new king reached Carthagena, Prim was murdered by assassins who were never discovered.

Revolution of 1868. Deposition of Isabella.

Republican and Monarchical Parties.

Regency of Serrano.

Amadeo of Savoy accepts the Crown.

The nominal reign of Amadeo lasted till February 1873. It was a scandalous episode. The Italian prince had put himself into a thoroughly false position, in which the nearest approach to friends he could find were intriguing politicians who sought to use him as a tool, and where every man of honest principles, royalist or republican, looked upon him as an intruder. The Carlists began to collect in the mountains. Republican agitations went on in the towns. At last a dispute in regard to the officering of the artillery gave the king an honourable excuse for resigning a throne on which both he and his wife had been treated with the utmost insolence.

Resignation of Amadeo.

The Republicans entered the place he left vacant simply because there was nobody to oppose them. Until January of the following year the country was given up to anarchy. The Republicans had undertaken to abolish the conscription, and many of the soldiers, taking them at their word, disbanded. The Carlists increased rapidly in numbers, and were joined by many Royalists, who looked upon them as the last resource. Bands of ruffians calling themselves "volunteers of liberty" were found to defend the Republic, and to terrorize society. A new Cortes was collected and proved a mere collection of hysterical ranters. Three presidents succeeded one another within a year, Pi y Margall, Salmeron and Castelar. Ministries changed every few days. As the Republic was to be federal when finally organized many parts of Spain proceeded to act independently. One party went beyond federalism and proposed to split Spain into cantons. The Cantonalists, who were largely galley slaves and deserters, seized the important harbour of Carthagena and the ships in it. The ships were taken out of their hands by the British and German squadrons. The spectacle of anarchy, and the stoppage in payment of taxes frightened the Republican deputies into some approach to sanity. Salmeron allowed General Pavia to restore order in Andalusia. When he gave place to Castelar, the eloquent Republican deputy, who was left unchecked by the recess, threw all his most eagerly avowed principles to the wind, raised a great conscription, and provided the means of reducing Carthagena and pushing the war against the Carlists with vigour. When the Cortes met again in January 1874, the extreme parties voted against Castelar on the 3rd of the month. Hereupon General Pavia, the governor of Madrid, turned the Cortes into the streets, to the relief of all sane men in the country. Serrano was appointed as head of the executive, and was mainly employed during the year in efforts to save Bilbao from falling into the hands of the Carlists. It had now become clear that the restoration of the Bourbons in the person of Don Alphonso, Isabella's son, was the only way of securing a final settlement. His civilian agents would have preferred to see him brought in by a Cortes. But on the 29th of December 1874 General Martinez Campos caused him to be proclaimed king at Murviedro by a brigade of troops, and the example there set was followed everywhere. Don Alphonso XII. landed in Barcelona on the 10th of January 1875.

Republican Interlude.

Castelar's Presidency.

Alphonso XII. King, 1874.

The Restored Monarchy, 1874–1900.—The first act of Alphonso was a royal decree confirming the appointment of Canovas del Castillo as prime minister. A strong Conservative administration was formed, to which Canovas admitted some men of the old parties of Queen Isabella's reign side by side with men who had played a part in the Revolution before they became his active auxiliaries in the Alphonsist propaganda in 1872 and 1873. This cabinet gave its chief attention for fifteen months to the pacification of the Peninsula, adopting a Conservative and Catholic policy which contributed quite as much as the great display of military resources to make the Pretender lose adherents and prestige from the moment that his cousin reached Madrid. The Church, the nobility and the middle classes soon pronounced for the new state of things. The Alphonsist armies, led by Marshals Campos and Jovellar, swept the Carlist bands from the right bank of the Ebro to the Pyrenees, and took their last strongholds in the eastern provinces, Cantavieja and Seo de Urgel. Not a few of the Carlist leaders accepted bribes to go abroad, and others put their swords at the disposal of the government for employment against the Cuban rebels. Then all the forces of King Alphonso under Marshal Quesada gradually closed round the remainder of the Carlist army in Navarre and in the Basque Provinces at the beginning of 1876. The young king himself was present at the close of the campaign, which sent his rival a fugitive across the French frontier, with the few thousand followers who had clung to his cause to the very end.

Directly the Carlist War was over, the government used part of the large army at its disposal to reinforce the troops which had been fighting the Cuban insurgents since 1869. Marshal Jovellar was sent out to Havana as governor-general, with Marshal Martinez Campos as commander-in-chief of the forces. In about eighteen months they managed to drive the rebels into the eastern districts of the island, Puerto Principe and Santiago de Cuba, and induced all but a few irreconcilable chiefs to accept a convention that became famous under the name of the peace treaty of Zanjon. Marshal Campos, who very soon succeeded Jovellar as governor-general of Cuba, for the first time held out to the loyalists of the island the prospect of reforms, fairer treatment at the hands of the mother country, a more liberal tariff to promote their trade, and self-government as the crowning stage of the new policy. He also agreed to respect the freedom of the maroons who had fled from their masters to join the Cubans during the ten years' war, and this led to Spain's very soon granting gradual emancipation to the remainder of the slaves who had stood by their owners. Marshal Campos was not allowed to carry out his liberal and conciliatory policy, which the reactionary party in the colony, *el partido espanol*, resented as much as their allies in the Peninsula.

The Cuban Insurrection.

Though much of his time and energies had been devoted to the re-establishment of peace at home and in the colonies from 1875 to 1880, Señor Canovas had displayed considerable activity and resolution in the reorganization of the monarchy. Until he felt sure of the early termination of the struggle with the pretender, he ruled in a dictatorial manner without the assistance of parliament. Royal decrees simply set aside most of the legislation and reforms of the Spanish Revolution. Universal suffrage alone was respected for a while and used as the means to call into existence the first Cortes of the Restoration in 1876. The electors proved, as usual, so docile, and they were so well handled by the authorities, that Canovas obtained a parliament with great majorities in both houses which voted a limited franchise to take the place of universal suffrage. Immediately afterwards they voted the constitution of 1876, which was virtually a sort of compromise between the constitution of 1845 in the reign of Isabella and the principles of the democratic constitution of the Revolution in 1869. For instance, liberty of conscience, established for the first time in 1869, was reduced to a minimum of toleration for Protestant worship, schools and cemeteries, but with a strict prohibition of propaganda and outward signs of faith. Trial by jury was abolished, on the plea that it had not worked properly. Liberty of associations and all public meetings and demonstrations were kept within narrow limits and under very close surveillance of the authorities. The municipal and provincial councils were kept in leash by intricate laws and regulations, much resembling those of France under the Second Empire. The political as well as the administrative life of the country was absolutely in the hands of the wire-pullers in Madrid; and their local agents, the governors, the mayors and the electoral potentates styled *los Caciques*, were all creatures of the minister of the interior at the head of Castilian centralization. The constitution of 1876 had created a new senate, of which half the members were either nominees of the Crown or sat by right of office or birth, and the other half were elected by the provinces of the Peninsula and the colonies, the clergy, the universities and the learned societies and academies. The House of Deputies, composed of 456 members, was elected by the limited franchise system in Spain and by an even more restricted franchise in the colonies, five-sixths of the colonists being deprived of representation. From the beginning of the Restoration the great statesman, who was nicknamed at the time the Richelieu of Alphonso XII.'s reign, established a system of government which lasted for a quarter of a century. He encouraged the men of the Revolution who wanted to bow to accomplished facts and make the best of the restricted amount of liberty remaining, to start afresh in national politics as a Dynastic Liberal party. From the moment that such former revolutionists as Sagasta, Ulloa, Leon y Castillo, Camacho, Alonzo Martinez and the marquis de la Vega de Armijo declared that they adhered to the Restoration, Canovas did not object to their saying in the same breath that they would enter the Cortes to defend as much as possible what they had achieved during the Revolution, and to protest and agitate, legally and pacifically, until they succeeded in re-establishing some day all that the first cabinet of Alphonso XII. had altered in the Constitution of 1869. The premier not only approved Sagasta's efforts to gather round him as many Liberals and Democrats as possible, but did not even oppose the return of Emilio Castelar and a few Republicans. He also countenanced the presence in the Cortes for the first time of 15 senators and 42 deputies to represent Cuba and Porto Rico, including a couple of home rulers. Thus Canovas meant to keep up the appearance of a constitutional and parliamentary government with what most Spaniards considered a fair proportional representation of existing parties, except the Carlists and the most advanced Republicans, who only crept into the House of Deputies in some later parliaments. Canovas ruled his own coalition of Conservatives and Catholics with an iron hand, managing the affairs of Spain for six years with only two short interruptions, when he stood aside for a few months, just long enough to convince the king that the Conservative party could not retain its cohesion, even under such men as Marshals Jovellar and Campos, if he did not choose to support them.

Internal Changes.

In the early years of the Restoration the king and Canovas acted in concert in two most delicate matters. Alphonso XII. agreed with his chief counsellor as to the expediency of keeping military men away from active politics. Canovas boldly declared in the Cortes that the era of military *pronunciamientos* had been for ever closed by the Restoration, and the king reminded the generals more than once that he intended to be the head of the army. The king and his prime minister were equally agreed about the necessity of showing the Vatican and the Church sufficient favour to induce them to cease coquetting with the pretender Don Carlos, but not so much as to allow the pope and the clergy to expect that they would tolerate any excessive Ultramontane influence in the policy of the Restoration. In regard to foreign policy, the king and Canovas both inclined to assist national aspirations in Morocco, and jealously watched the relations of that empire with other European powers. This desire to exercise a preponderant influence in the affairs of Morocco culminated in the Madrid conference of 1880. Preponderant influence was not attained, but the conference led to a treaty which regulated the consular protection extended to the subjects of Morocco.

In 1878, in spite of the well-known hostility of his mother to the Montpensiers, and in spite of his ministers' preferences for an Austrian match, King Alphonso insisted upon marrying the third daughter of the duke of Montpensier, Doña Mercedes, who only survived her marriage five months. Barely seventeen months after the death of his first wife, the king listened to the advice of Canovas and married, in November 1879, the Austrian archduchess Maria Christina of Habsburg. In general matters the king allowed his ministers much liberty of action. From 1875 to 1881, when not too much engrossed in more pressing affairs, his governments turned their attention to the reorganization of the finances, the resumption of payment of part of the debt coupon, and the consolidation of the colonial and imperial floating debts. They swerved from the mild free trade policy which was inaugurated by Señor Figuerola and by Prim at the beginning of the Revolution, and to which was due the remarkable progress of the foreign trade. This

Marriage of Alphonso XII.

went on almost continuously as long as the régime of moderate tariffs and commercial treatises lasted, *i.e.* until 1890.

Liberal Administrations. In 1881 the Dynastic Liberals began to show impatience at being kept too long in the cold shade of opposition. Their chief, Sagasta, had found allies in several Conservative and Liberal generals—Campos, Jovellar, Lopez-Dominguez and Serrano—who had taken offence at the idea that Canovas wanted to monopolize power for civil politicians. These allies were said to be the dynastic and monarchical ballast, and in some sort the dynastic guarantees of liberalism in the eyes of the court. Canovas came to the conclusion that it was expedient for the Restoration to give a fair trial to the quondam revolutionists who coalesced under Sagasta in such conditions. He arranged with the king to moot a series of financial projects the acceptance of which by His Majesty would have implied a long tenure of office for the Conservatives, and so Alphonso XII. found a pretext to dissent from the views of his premier, who resigned on the spot, recommending the king to send for Sagasta. The Liberal administration which that statesman formed lasted two years and some months. The policy of Sagasta in domestic affairs resembled that of Canovas. The Liberals had to act cautiously and slowly, because they perceived that any premature move towards reform or democratic legislation would not be welcome at court, and might displease the generals. Sagasta and his colleagues therefore devoted their attention chiefly to the material interests of the country. They made several treaties of commerce with European and Spanish-American governments. They reformed the tariff in harmony with the treaties, and with a view to the reduction of the import duties by quinquennial stages to a fiscal maximum of 15% *ad valorem*. They undertook to carry out a general conversion of the consolidated external and internal debts by a considerable reduction of capital and interest, to which the bondholders assented. They consolidated the floating debt proper in the shape of a 4% stock redeemable in 40 years, of which £70,000,000 was issued in 1882 by Señor Camacho, the greatest Spanish financier of the century. Sagasta was not so fortunate in his dealings with the anti-dynastic parties, and the Republicans gave him much trouble in August 1883. The most irreconcilable Republicans knew that they could not expect much from popular risings in great towns or from the disaffected and anarchist peasantry in Andalusia, so they resorted to the old practice of barrack conspiracies, courting especially the non-commissioned officers and some ambitious subalterns. The chief of the exiles, Don Manuel Ruiz Zorilla, who had retired to Paris since the Restoration, organized a military conspiracy, which was sprung upon the Madrid government at Badajoz, at Seo de Urgel, and at Santo Domingo in the Ebro valley. This revolutionary outbreak was swiftly and severely repressed. It served, however, to weaken the prestige of Sagasta's administration just when a Dynastic Left was being formed by some discontented Liberals, headed by Marshal Serrano and his nephew, General Lopez-Dominguez. They were joined by many Democrats and Radicals, who seized this opportunity to break off all relations with Ruiz Zorilla and to adhere to the monarchy. After a while Sagasta resigned in order to let the king show the Dynastic Left that he had no objection to their attempting a mildly democratic policy, on condition that the Cortes should not be dissolved and that Sagasta and his Liberal majorities in both houses should grant their support to the cabinet presided over by Señor Posada Herrera, a former Conservative, of which the principal members were General Lopez-Dominguez and Señores Moret, Montero Rios and Becerra. The support of Sagasta did not last long, and he managed with skill to elbow the Dynastic Left out of office, and to convince all dissentients and free lances that there was neither room nor prospect for third parties in the state between the two great coalitions of Liberals and Conservatives under Sagasta and Canovas. When Posada Herrera resigned, the Liberals and Sagasta did not seem much displeased at the advent to power of Canovas in 1884, and soon almost all the members of the Dynastic Left joined the Liberal party.

Foreign Policy. From 1881 to 1883, under the two Liberal administrations of Sagasta and Posada Herrera, the foreign policy of Spain was much like that of Canovas, who likewise had had to bow to the king's very evident inclination for closer relations with Germany, Austria and Italy than with any other European powers. Alphonso XII. found a very willing minister for foreign affairs in the person of the marquis de la Vega de Armijo, who cordially detested France and cared as little for Great Britain. The Red-books revealed very plainly the aims of the king and his minister. Spanish diplomacy endeavoured to obtain the patronage of Italy and Germany with a view to secure the admission of Spain into the European concert, and into international conferences whenever Mediterranean and North African questions should be mooted. It prepared the way for raising the rank of the representatives of Spain in Berlin, Vienna, Rome, St Petersburg and London to that of ambassadors. In Paris the country had been represented by ambassadors since 1760. The Madrid foreign office welcomed most readily a clever move of Prince Bismarck's to estrange Spain from France and to flatter the young king of Spain. Alphonso XII. was induced to pay a visit to the old emperor William in Germany, and during his stay there, in September 1883, he was made honorary colonel of a Uhlan regiment quartered at Strassburg. The French people resented the act, and the Madrid government was sorely embarrassed, as the king had announced his intention of visiting Paris on his way back from Germany. Nothing daunted by the ominous attacks of the French people and press, King Alphonso went to Paris. He behaved with much coolness and self-possession when he was met in the streets by a noisy and disgraceful demonstration. The president of the Republic and his ministers had to call in person on their guest to tender an apology, which was coldly received by Alphonso and his minister for foreign affairs. After the king's return, the German emperor sent his son the crown prince Frederick, with a brilliant suite, to the Spanish capital, where they were the guests of the king for several days. Until the end of his reign Alphonso XII. kept up his friendly relations with the German Imperial family and with the German government.

The close of the reign of Alphonso XII. was marked by much trouble in domestic politics, and by some great national calamities and foreign complications, while the declining health of the monarch himself cast a gloom over the court and governing classes. The last Conservative cabinet of this reign was neither popular nor successful. When the cholera appeared in France, quarantine was so rigorously enforced in the Peninsula that the external trade and railway traffic were grievously affected. On Christmas night, 1884, an earthquake caused much damage and loss of life in the provinces of Granada and Malaga. Many villages in the mountains which separate those provinces were nearly destroyed. At Alhama, in Granada, more than 1000 persons were killed and injured, several churches and convents destroyed, and 300 houses laid in ruins. King Alphonso went down to visit the district, and distributed relief to the distressed inhabitants, despite his visibly failing health. He held on gallantly through the greater part of 1885 under great difficulties. In the Cortes the tension in the relations between the government and the opposition was growing daily more serious. Outside, the Republicans and Carlists were getting troublesome, and the tone of their press vied with that of the Liberals in their attacks on the Conservative cabinet. Then, to make matters worse, an outbreak of cholera occurred in the eastern provinces of the kingdom. The epidemic spread rapidly over the Peninsula, causing great havoc in important cities like Granada, Saragossa and Valencia. The authorities confessed that 105,000 persons died of cholera in the summer and autumn of 1885, being on an average from 41 to 56% of those attacked.

In September a conflict arose between Spain and Germany which had an adverse effect upon his health. Prince Bismarck looked upon the rights of Spain over the Caroline Islands in the Pacific as so shadowy that he sent some German war-ships to take possession of a port in the largest island of the group. The action of Germany caused great indignation in Spain, which led, in Madrid, to imposing demonstrations. The government got alarmed when the mob one night attacked the German embassy, tore the arms of the empire from the door of the consulate, and dragged the escutcheon to the Puerto del Sol, where it was burnt amid much uproar. The troops had to be called out to restore order. Alphonso alone remained cool, and would not listen to those who clamoured for a rupture with Germany. He elected to trust to diplomacy; and Spain made out such a good case for arbitration, on the ground of her ancient rights of discovery and early colonization, that the German emperor, who had no desire to imperil the dynasty and monarchy in Spain, agreed to submit the whole affair to the pope, who gave judgment in favour of Spain.

Death of Alphonso XII.

After his return to Madrid the king showed himself in public less than usual, but it was clear to all who came in contact with him that he was dying. Nevertheless, in Madrid, Canovas would not allow the press to say a word. Indeed, in the ten months before the death of Alphonso XII. the Conservative cabinet displayed unprecedented rigour against the newspapers of every shade. The Dynastic, Liberal and Independent press, the illustrated papers and the satirical weeklies fared no better than the Republicans, Socialists and Carlists, and in 60 days 1260 prosecutions were ordered against Madrid and provincial papers. At last, on the 24th of November 1885, the truth had to be admitted and on the morning of the 25th the end came.

Regency of Queen Christina.

It was no wonder that the death of a king who had shown so much capacity for rule, so much unselfish energy and courage, and so many amiable personal qualities, should have made Spaniards and foreigners extremely anxious about the prospects of the monarchy. Alphonso XII. left no male issue. He had two daughters, the princess of the Asturias, born in 1880, and the Infanta Maria Theresa, born in 1882. At the time of his death it had not been officially intimated that the queen was *enceinte*. The *Official Gazette* did not announce that fact until three months after the demise of the sovereign. On the 17th of May 1886, six months after the death of Alphonso XII., his posthumous son, Alphonso XIII., was born at the palace of Madrid. Six months before this event definitely settled the question of the succession to the throne, the royal family and its councillors assembled to take very important decisions. There could be no doubt that under the constitution of 1876 the widowed queen was entitled to the regency. Doña Maria Christina calmly presided over this solemn council, listening to the advice of Marshal Campos, always consulted in every great crisis; of Captain-General Pavia, who answered for the loyalty of the capital and of its garrison; of the duke de Sexto, the chief of the household; of Marshal Blanco, the chief of the military household; and of all the members of the cabinet and the presidents of the Senate and Congress assembled in the presence of the queen, the ex-queen Isabella, and the Infanta Isabella. All looked chiefly to Marshal Campos and Canovas del Castillo for statesmanlike and disinterested advice. The question was whether it would be expedient to continue the policy of the late king and of his last cabinet. Canovas assured the queen-regent that he was ready to undertake the task of protecting the new state of things if it was thought wise to continue the Conservative policy of the late king, but in the circumstances created by his death, he must frankly say that he considered it advisable to send for Señor Sagasta and ask him to take the reins of government, with a view to inaugurate the regency under progressive and conciliatory policy.

Sagasta was summoned to El Pardo, and the result of his interview with the queen-regent, Canovas and the generals, was the understanding ever afterwards known as the pact of El Pardo, the corner-stone of the whole policy of the regency, and of the two great statesmen who so long led the great dynastic parties and the governments of Doña Christina. It was agreed that during the first years of the regency, Canovas and Sagasta would assist each other in defending the institutions and the dynasty. Sagasta made no secret of the fact that it was his intention to alter the laws and the constitution of the monarchy so as to make them very much resemble the constitution of the Revolution of 1868, but he undertook to carry out his reform policy by stages, and without making too many concessions to radicalism and democracy, so that Canovas and his Conservative and Catholic followers might bow to the necessities of modern times after a respectable show of criticism and resistance. The generals assured the queen-regent and the leaders of the dynastic parties that the army might be counted upon to stand by any government which was sincerely determined to uphold the Restoration against Republicans and Carlists. Sagasta left the palace to form the first of several cabinets over which he presided continuously for five years. He took for colleagues some of the strongest and most popular statesmen of the Liberal party, virtually representing the three important groups of men of the Revolution united under his leadership—veteran Liberals like Camacho and Venancio Gonzalez; Moderates like Alonzo Martinez, Gamazo and Marshal Jovellar; and Democrats like Moret, Montero Rios and Admiral Beranger. The new cabinet convoked the Cortes elected under the administration of Canovas in 1884, and the Conservative majorities of both houses, at the request of Canovas, behaved very loyally, voting supplies and other bills necessary to enable the government to be carried on until another parliament could be elected in the following year, 1886.

Republican and Carlist Intrigues.

Pending the dissolution and general election, Sagasta and his colleagues paid most attention to public peace and foreign affairs. A sharp look-out was kept on the doings of the Republicans, whose arch-agitator, Ruiz Zorilla, in Paris displayed unusual activity in his endeavours to persuade the Federals, the Intransigeants, and even the Opportunists of Democracy that the times were ripe for a venture. Ruiz Zorilla found no response from the Republican masses, who looked to Pi y Margall for their watchword, nor from the Republican middle classes, who shared the views of Salmeron, Azcarate and Pedregal as to the inexpediency of revolutionary methods. Castelar, too, raised his eloquent protest against popular risings and barrack conspiracies. The Carlists showed equal activity in propaganda and intrigues. Sagasta derived much benefit from the divisions which made democracy powerless; and he was able to cope with Carlism chiefly because the efforts of the pretender himself abroad, and of his partisans in Spain, were first restrained and then decisively paralysed by the influence of foreign courts and governments, above all by the direct interference of the Vatican in favour of the Spanish regency and of the successor of Alphonso XII. The young and most impatient adherents of Carlism vainly pleaded that such an opportunity would not soon be found again, and threatened to take the law into their own hands and unfurl the flag of *Dios, Patria, y Rey* in northern and central Spain. Don Carlos once more showed his well-known lack of decision and dash, and the Carlist scare passed away. Pope Leo XIII. went even further in his patronage, for he consented to be the godfather of the posthumous son of Alphonso XII., and he never afterwards wavered in the steady sympathy he showed to Alphonso XIII. He was too well acquainted with the domestic politics of the Peninsula to suppose that Carlism could ever do more than disturb for a while the tranquillity of Spain. He did not wish to stake the interests of the Church on a cause which could only revive against her the old animosities of Spanish liberalism and democracy, so roughly displayed in the years 1836 and 1868. Doña Christina, apart from the dictates of gratitude towards the head of her Church for the kindness shown to her son and government, was a zealous Catholic. She proved all through her regency that she not only relied upon the support of the Vatican and of the prelates, but that she was determined to favour the Church and the religious foundations in every possible way. Her purse was always open to assist convents, monasteries, and religious works and societies of all kinds, as long as they were under the management of the Church. She became regent when Spain had felt the consequences of the expulsion of the Jesuits and other religious orders from France after the famous Jules Ferry laws, which aimed at placing these orders more under state control, to which they declined to submit. They selected Spain as an excellent field of enterprise; and it must be said that all the governments of the regency showed so much indulgence towards the Catholic revival thus started, that in less than a decade the kingdom was studded with more convents, monasteries, Jesuit colleges, Catholic schools, and foundations than had existed in the palmy days of the houses of Austria and Bourbon in the 17th and 18th centuries. A wave of Clericalism and ultra-Catholic influences swept over the land, affecting the middle classes, the universities and learned societies, and making itself very perceptible also among the governing classes and both dynastic parties, Liberals and Conservatives.

Europe and the Regency.

Next in importance to papal protection was the favourable attitude of all the European governments towards the queen-regent and, later, towards her son. The court and government of Germany vied with the Austrian and Italian royal families and governments in showing sympathy to the widow of Alphonso XII. Republican France and the tsar made as cordial demonstrations as Queen Victoria and her government, and Switzerland, Belgium, Holland and others followed suit. The Spanish foreign office received every assurance that friendly governments would watch the Carlists and Republicans, to prevent them from using their territories as a basis for conspiracies against the peace of Spain. The statesmen of both dynastic parties, from the beginning of the regency, agreed to observe strict neutrality in European affairs, in order to avoid complications fraught with evil consequences for the monarchy and the dynasty in the unsettled state of the country. This neutrality was maintained until the close of the 19th century.

Policy of Sagasta.

Sagasta conducted the first general election in 1886 much after the usual precedents. The Long Parliament of the regency was composed of considerable Liberal majorities in both houses, though Sagasta had allowed a larger share than Canovas was wont to do to the minorities, so much so that on the opposition benches the Republicans of various shades were represented by their most eminent leaders, the Carlists had a respectable group, and the Conservatives a strong muster, flanked by a group of dissentients. The first Cortes of the regency in five sessions did really good and substantial work. A civil code was carefully drawn up by Señor Alonzo Martinez, in order to consolidate the very heterogeneous ancient legislation of the monarchy and the local laws of many provinces, especially Catalonia, Aragon, Valencia, Navarre, and the Basque territory. Trial by jury was re-established for most crimes and offences. The laws regulating the rights of association and public meeting, the liberty of the press, and other rights of the subject were reformed on liberal and more tolerant lines. Finance and trade received attention. Some commercial treaties and agreements were made, including one with Great Britain, which proved highly beneficial to home trade, and the tariff was altered, in spite of much resistance on the part of the Protectionists. In his progressive policy Sagasta was actively and usefully supported by the chief of the moderate Republicans, Emilio Castelar, who recommended his partisans to vote with the Liberal party, because he confessed that bitter experience had taught him that liberties and rights were better attained and made stable by pacific evolution than by revolution. He laid most stress upon this axiom when, in September 1886, Ruiz Zorilla suddenly sprang upon Sagasta a military and revolutionary movement in the streets and barracks of Madrid. The military authorities acted with promptitude, the rebels being pursued, dispersed and arrested. General Marina and several other officers were condemned to death by court martial, but Queen Christina commuted the sentence into penal servitude, and the ministers of war and marine retired from the cabinet in consequence. Very shortly afterwards, another war minister, General Castillo, attempted to strike at the root of military insubordination, and simultaneously in every garrison of the kingdom the senior sergeants, more than 1000 in all, were given their discharge and ordered to start for their homes on the spot. The lesson produced a good result, as no trace of revolutionary work revealed itself among the non-commissioned officers after 1886. As time wore on, Sagasta found it difficult to maintain discipline in the ranks of the Liberal party. He was obliged to reconstruct the cabinet several times in order to get rid of troublesome colleagues like General Cassola, who wanted to make himself a sort of military dictator, and Camacho, whose financial reforms and taxation schemes made him unpopular He had more often to reorganize the government in order to find seats in the cabinet for ambitious and impatient worthies of the Liberal party—not always with success, as Señor Martos, president of the Congress, and the Democrats almost brought about a political crisis in 1889. Sagasta cleverly affected to resign and stand aside, so that Señor Alonzo Martinez might vainly attempt to form an intermediary cabinet. Canovas, who was consulted by the queen when Alonzo Martinez failed, faithfully carried out the pact of El Pardo and advised Her Majesty to send for Sagasta again, as he alone could carry out what remained to be done of the Liberal programme. Sagasta reconstructed his ministry for the last time, and announced his intention to make the re-establishment of universal suffrage the crowning act of the Liberal policy, knowing very well that he would thus rally round him all the Liberals, Democrats and Republicans in the last session of the Long Parliament. The Suffrage Bill was carried through the Senate and Congress in the spring of 1890 after protracted debates, in which the Conservatives and many military politicians who had previously been regarded as the allies of Sagasta did their best to obstruct the measure. Marshals Campos, Jovellar and Novaliches, and Generals Pavia, Primo de Rivera, Daban and others, were angry with Sagasta and the Liberals not only because they deemed their policy too democratic, but because they ventured to curb the insubordinate attitude of general officers, who shielded themselves behind the immunities of their senatorial position to write insolent letters to the war minister on purely professional questions. Spanish generals of *pronunciamiento* fame thought it perfectly logical and natural that sergeants and subalterns should be shot or sent to penal servitude for acts of indiscipline, but if an insubordinate general was sent to a fortress under arrest for two months they publicly demonstrated their sympathy with the offender, made angry speeches against their hierarchical chief, the war minister, in the Senate, and dared to call upon the queen-regent to make representations, which unfortunately were listened to, according to the worst precedents of the Spanish monarchy. The increasing violence of the Conservative press and opposition, the divisions developing in the ranks of liberalism, and the restlessness of the agricultural protectionists led by Señor Gamazo, did not weigh so much in the balance at court against Sagasta as the aggressive attitude of the military politicians. Sagasta held on as long as was necessary to secure the promulgation of the universal suffrage law, but he noticed that the queen-regent, when he waited upon her for the despatch of public business, showed almost daily more impatience for a change of policy, until at last, in July 1890, she peremptorily told him that she considered the time had come for calling the Conservatives and their military patrons to her councils. Sagasta loyally furnished the queen with a constitutional pretext for carrying out her desire, and tendered the resignation of the whole cabinet, so that Her Majesty might consult, as usual, the party leaders and generals on the grave question of the expediency of entrusting to new ministers or to the Liberals the mission of testing the new electoral system. Queen Christina on this occasion acted exactly as she henceforth did in all ministerial crises. She slowly consulted the magnates of all parties with apparent impartiality, and finally adopted the course which it was an open secret she had decided upon *in pectore* beforehand.

Canovas gathered round him most of the prominent Conservative and Catholic statesmen. The first step of the new cabinet was calculated to satisfy the protectionist aspirations which had spread in the kingdom about the same time that most Continental countries were remodelling and raising their tariffs. The Madrid government used an authorization which Sagasta had allowed his Long Parliament to vote, to please Señor Gamazo and the Liberal representatives of agricultural interests, empowering the government to revise and increase all tariff duties not covered by the then existing treaties of commerce. This was the case with most of the products of agriculture and with live stock, so Canovas and his finance minister made, by royal decree, an enormous increase in the duties on these classes of imports, and particularly on breadstuffs. Then, in 1891, they denounced all the treaties of commerce which contained clauses stipulating most-favoured-nation treatment, and they prepared and put in force in February 1892 a protectionist tariff which completely reversed the moderate free-trade policy which had been so beneficial to the foreign commerce of Spain from 1868 to 1892. Not a few nations retaliated with higher duties upon Spanish exports, and France raised her wine duties to such an extent that the exports of wines to that country dropped from £12,500,000 before 1892 to £2,400,000 in 1893 and the following years. The effects of a protectionist policy verging upon prohibition were soon sharply felt in Spain. Foreign exchanges rose, exports decreased, the railway traffic declined, and the commercial classes and consumers of foreign goods and products were loud in their protests. Industrial interests alone benefited, and imported more raw materials, chemicals, and coal and coke, which naturally influenced the exchanges adversely. Spain only attempted to make new treaties of commerce with Holland, Norway, Sweden, Denmark and Switzerland. The Great Powers contented themselves with securing by agreements the same treatment for their commerce in Spain as that granted by those five treaties. The Protectionists in 1893 wrecked a treaty of commerce with Germany in the Senate; and Spain subsequently persevered in her protectionist policy. During his two and a half years' stay in office Canovas had not so much trouble with the opposition as with the divisions which sprang up in the Conservative ranks, though he fancied that he had managed the general election in 1891 so as to secure the customary docile majorities. The split in the Conservative camp originated in the rivalry between the two principal lieutenants of Canovas, Romero Robledo and Francisco Silvela. The latter and a strong and influential body of Conservatives, chiefly young politicians, dissented from the easy-going views of Romero Robledo and of Canovas on the expediency of reforms to correct the notorious and old-standing abuses and corruption of the municipalities, especially of Madrid. When Canovas found himself deserted on so delicate a matter by a numerous section of his party, he resigned, and advised the queen to send for Sagasta and the Liberals.

A Protectionist Régime.

Sagasta took office very reluctantly, as he considered a change of policy premature. He conducted the general election with much regard for the wishes of the opposition, and out of 456 seats in the Lower House allowed them to have more than 170, the Conservatives getting nearly 100 and the Republicans 30. He had to settle some knotty questions, foremost a conflict with Morocco, which was the consequence of the aggression of the unruly Riff tribes upon the Spanish outposts around Melilla. Reinforcements were tardily sent out; and in a second attack by the Arabs the Spanish forces lost heavily, and their commander, General Margallo, was killed. Public opinion was instantly fired, and the press called so loudly for revenge that the government sent to Melilla no less a personage than Marshal Campos, at the head of 29 generals and 25,000 men. The sultan of Morocco lost no time in censuring the behaviour of the Riff tribes, and in promising that he would chastise them. Marshal Campos was sent to Fez to make a treaty, in which he obtained ample redress and the promise of an indemnity of £800,000, which Morocco punctually paid.

Difficulty with Morocco.

Colonial affairs gave Sagasta much to do. He had given seats in his cabinet to Señor Antonio Maura as colonial secretary and to Señor Gamazo, his brother-in-law, as finance minister. These two moderate Liberals acted in concert to grapple with colonial questions, which in 1894 had assumed a very serious aspect. Spain had received many ominous warnings. Marshal Campos, on returning from Cuba in 1879, had advocated some concessions to satisfy the legitimate aspirations of the majority of the colonists. In 1886, in the first parliament of the regency, Cuban autonomist deputies divided the house on a motion in favour of home rule and of an extension of the franchise in Cuba. This motion was negatived by all the Conservatives, by most of the Dynastic Liberals and by some of the Republicans. The majority of Spaniards were kept by the government and the press quite in the dark about the growth of disaffection in Cuba, so that they were loath to listen to the few men, soldiers and civilians, courageous enough to raise the note of alarm during the ten years before the final catastrophe. For no other reason did the minister for the colonies, Señor Maura, in 1894 fail to convince the Cortes, and even the Liberal party, that his very moderate Cuban Home Rule Bill was an indispensable and wise, though tardy, attempt to avert a conflict which many plain symptoms showed to be imminent in the West Indies. Maura was warmly supported in Congress by the Cuban home rulers and by some far-sighted Liberals and Republicans. Nevertheless, his bill did not find favour with the Conservatives or the majority of the Liberals, and Sagasta, trimming according to his inveterate habit, found a pretext to get rid of Maura and Gamazo. In the place of Maura he found a more pliant minister for the colonies, Señor Abarzuza, who framed a Cuban Reform Bill so much short of what his predecessor had thought an irreducible minimum of concessions, that it was censured in Havana by all the colonial Liberals and home rulers, and by their representatives in Madrid. The latter at the last moment recorded their votes in favour of the Abarzuza Bill when they perceived that a strange sort of eleventh-hour presentiment was about to make all the Spanish parties vote this insufficient reform. Before it could be promulgated, the tidings came of a separatist rising in the old haunts of Creole disaffection near Santiago de Cuba. Sagasta sent about 12,000 men to reinforce the 15,000 soldiers in Cuba under General Callaga, and was preparing more when a characteristically Spanish ministerial crisis arose. The subalterns of the Madrid garrison took offence at some articles published by Radical newspapers, and they attacked the editorial offices. Neither the war minister nor the commanders of the garrison chose to punish the offenders, and sooner than endorse such want of discipline, Sagasta and the Liberal party once more made way for Canovas. A very few days after he assumed office Canovas received information concerning the spread of the rising in Cuba which induced him to send out Marshal Campos with 30,000 men. He allowed Marshal Campos much liberty of action, but dissented from his views on the expediency of allowing him to offer the loyalists of Cuba as much home rule as would not clash with the supremacy of Spain. The prime minister declared that the Cubans must submit first, and then the mother country would be generous.

The Cuban Question.

Before a year had passed, in view of the signal failure of Marshal Campos, the Madrid government decided to send out General Weyler, who had made himself famous in the Philippines and at Barcelona for his stern and cruel procedure against disaffection of every kind. He showed the same merciless spirit in dealing with the Cubans; and he certainly cleared two-thirds of the island of Creole bands, and stamped out disaffection by vigorous military operations and by obliging all the non-combatants who sympathized with the rebels in arms to elect between joining them in the bush, La Manigua, or residing within the Spanish lines. This system might probably have succeeded if the United States had not

General Weyler's Campaign.

countenanced the sending of supplies of every kind to the rebels, and if American diplomacy had not again and again made representations against Weyler's ruthless policy. Canovas so fully comprehended the necessity of averting American intervention that he listened to the pressing demands of secretary Olney and of the American minister in Madrid, Hannis Taylor, and laid before the Cortes a bill introducing home rule in Cuba on a more liberal scale than Maura, Abarzuza and Sagasta had dared to suggest two years before. Canovas did not live to see his scheme put into practice, as he was assassinated by an anarchist at the baths of Santa Agueda, in the Basque Provinces, on the 9th of August 1897. The queen-regent appointed General Azcarraga, the war minister, as successor to Canovas; and a few weeks later President McKinley sent General Woodford as representative of the United States at the court of Madrid. At the end of September 1897 the American minister placed on record, in a note handed by him at San Sebastian to the minister for foreign affairs, the duke of Tetuan, a strongly-worded protest against the state of things in Cuba, and demanded in substance that a stop should be put to Weyler's proceedings, and some measures taken to pacify the island and prevent the prolongation of disturbances that grievously affected American interests. Less than a fortnight after this note had been delivered, the Conservative cabinet resigned, and the queen-regent asked Sagasta to form a new administration. The Liberal government recalled Weyler, and sent out, as governor-general of Cuba, Marshal Blanco, a conciliatory and prudent officer, who agreed to carry out the home-rule policy which was concerted by Señor Moret and by Sagasta, with a view to obtain the goodwill of the president of the United States. If things had not already gone too far in Cuba, and if public opinion in the United States had not exercised irresistible pressure on both Congress and president, the Moret home-rule project would probably have sufficed to give the Cubans a fair amount of self-government. All through the winter of 1897–1898 the Madrid government took steps to propitiate the president and his government, even offering them a treaty of commerce which would have allowed American commerce to compete on equal terms with Spanish imports in the West Indies and defeat all European competition. But the blowing up of the American cruiser "Maine" in the port of Havana added fuel to the agitation in the United States against Spanish rule in Cuba. When Congress met in Washington the final crisis was hurried on. Spain appealed in vain to European mediation, to the pope, to courts and governments. All, with the exception of Great Britain, showed sympathy for the queen-regent and her government, but none were disposed to go beyond purely platonic representations in Washington.

War with the United States.

At last, on the 20th of April 1898, when the Spanish government learned that the United States minister, General Woodford, had been instructed by telegraph to present an ultimatum demanding the cessation of hostilities in Cuba, with a view to prepare for the evacuation of the island by the Spanish forces, Sagasta decided to give General Woodford his passports and to break off official relations with the United States. It was an open secret that this grave decision was not taken at the cabinet council presided over by the queen without a solemn protest by Señor Moret and the ministers of war and marine that the resources of Spain were totally inadequate for a struggle with the United States. These protests were overruled by the majority of the ministers, who invoked dynastic and monarchical considerations in favour of a desperate stand, however hopeless, in defence of the last remnants of the colonial empire of Spain. Reckless as was the course adopted, it was in touch with the feelings of the majority of a nation which had been to the very end deceived by the government and by the press not only in regard to its own resources, but also in regard to those of the United States and of the colonists in arms in Cuba and in the Philippine Islands. The sequel is soon told. The Spanish fleet in the Far East was defeated in Manila Bay by Admiral Dewey. Admiral Cervera's squadron was destroyed outside the Bay of Santiago de Cuba by the American fleet under Admirals Sampson and Schley. All communication between Spain and her colonies was thus cut off. An American expedition landed near Santiago, and the Spanish garrison surrendered after a fortnight's show of resistance. Very shortly afterwards, at the end of July, Spain sued for peace through the mediation of French diplomacy, which did not obtain much from President McKinley. It was agreed that hostilities should cease on sea and land, but that Spain should evacuate Cuba and Porto Rico pending the negotiations for a peace treaty which were to begin in Paris at the end of September 1898. In the meantime Manila and its garrison had surrendered to the Americans. The agreement of the 9th of August, signed by M. Cambon, the French ambassador in Washington, in the name of Spain, clearly stipulated that her rule in the New World must be considered at an end, and that the fate of the Philippines would be settled at the Paris negotiations. Unfortunately, Spain indulged in the illusion that America would perhaps respect her rights of sovereignty in the Philippine Islands, or pay a considerable sum for their cession and recognize the debts of Cuba and of the Philippines. The American commission, presided over by secretary Day in Paris, absolutely refused to admit the Spanish contention that the United States or the new administration in Cuba and the Philippines should be saddled with several hundred million dollars of debts, contracted by the colonial treasuries, and guaranteed by Spain, almost entirely to maintain Spanish rule against the will of the Cubans and Filipinos. Spain could not help assenting to a treaty by which she renounced unconditionally all her rights of sovereignty over Cuba and Porto Rico and ceded the Philippine and Sulu Islands and the largest of the Marianne Islands in consideration of the payment of four millions sterling by America. Thus ended a struggle which only left Spain the Carolines and a few other islands in the Pacific, which she sold to Germany in 1899 for £800,000, and a couple of islands which were left out in the delimitation made by the Paris peace treaty of the 12th of December 1898, and for which America paid £20,000 in 1900.

Financial and Political Reorganization.

The consequences of the war and of the loss of the colonies were very serious for Spanish finance. The national debt, which consisted before the war of £234,866,500 of external and internal consols and redeemable debts, and £24,250,000 of home floating debt, was increased by £46,210,000 of Cuban and Philippine debts, which the Cortes had guaranteed, and by £60,000,000 of debts contracted at a high rate of interest, and with the national guarantee, to meet the expenses of the struggle with the colonies and of the war with the United States. These additional burdens rendered it necessary that taxation and the budget should be thoroughly reorganized. Sagasta and the Liberal party would gladly have undertaken the reorganization of Spain and her finances, but the issue of the war and the unavoidable peace treaty had so evidently damaged their popularity in the country and their credit at court, that the government seized the pretext of an adverse division in the Senate to resign. The Liberals left office after having done all that was morally and materially possible, considering the extremely difficult, indeed inextricable, situation in which they found the country in October 1897. The task of reorganization was confided by the queen-regent to Señor Silvela, who had been universally recognized as the leader of the Conservatives and Catholics after the death of Canovas del Castillo. Silvela endeavoured to unite in what he styled a Modern Conservative party the bulk of the followers of Canovas; the Ultramontanes, who were headed by General Polavieja and Señor Pidal; the Catalan Regionalists, whose leader, Duran y Bas, became a cabinet minister; and his own personal following, of whom the most prominent were the home secretary, Señor Dato, and the talented and energetic finance minister, Señor Villaverde, upon whose shoulders rested the heaviest part of the task of the new cabinet. Silvela lacked the energy and decision which had been the characteristics of Canovas. He behaved constantly like a wary and cautious trimmer, avoiding all extreme measures, shaking off compromising allies like the Ultramontanes and the Regionalists, elbowing out of the cabinet

General Polavieja when he asked for too large credits for the army, taking charge of the ministry of marine to carry out reforms that no admiral would have ventured to make for fear of his own comrades, and at last dispensing with the services of the ablest man in the cabinet, the finance minister, Señor Villaverde, when the sweeping reforms and measures of taxation which he introduced raised a troublesome agitation among the taxpayers of all classes. Villaverde, however, had succeeded in less than eighteen months in giving a decisive and vigorous impulse to the reorganization of the budget, of taxation and of the home and colonial debts. He resolutely reformed all existing taxation, as well as the system of assessment and collection, and before he left office he was able to place on record an increase of close upon three millions sterling in the ordinary sources of revenue. His reorganization of the national debt was very complete; in fact, he exacted even more sacrifices from the bondholders than from other taxpayers. The amortization of the home and colonial debts was suppressed, and the redeemable debts of both classes were converted into 4 % internal consols. The interest on all colonial debts ceased to be paid in gold, and was paid only in pesetas, like the rest of the internal debts, and like the external debt held by Spaniards. Alone, the external debt held by foreigners continued to enjoy exemption from taxation, under the agreement made on the 28th of June 1882 between the Spanish government and the council of foreign bondholders, and its coupons were paid in gold. The Cortes authorized the government to negotiate with the foreign bondholders with a view to cancelling that agreement. This, however, they declined to do, only assenting to a conversion of the 4 % external debt into a $3\frac{1}{2}$% stock redeemable in sixty-one years.

After parting with Villaverde, Silvela met with many difficulties, and had much trouble in maintaining discipline in the heterogeneous ranks of the Conservative party. He had to proclaim not only such important provinces as Barcelona, Valéncia and Bilbao, but even the capital of Spain itself, in order to check a widespread agitation which had assumed formidable proportions under the direction of the chambers of commerce, industry, navigation and agriculture, combined with about 300 middle-class corporations and associations, and supported by the majority of the gilds and syndicates of taxpayers in Madrid and the large towns. The drastic measures taken by the government against the National Union of Taxpayers, and against the newspapers which assisted it in advocating resistance to taxation until sweeping and proper retrenchment had been effected in the national expenditure, checked this campaign in favour of reform and retrenchment for a while. Silvela's position in the country had been much damaged by the very fact of his policy having fallen so much short of what the nation expected in the shape of reform and retrenchment. At the eleventh hour he attempted to retrieve his mistake by vague promises of amendment, chiefly because all the opposition groups, above all Sagasta and the Liberals, announced their intention of adopting much the same programme as the National Union. The attempt was unsuccessful, and on the 6th of March 1901 a Liberal government, under the veteran Sagasta, was once more in office. (A. E. H.)

Parties and Conflicts, 1900–1910.—The loss of nearly all that remained of her colonial empire, though in appearance a crowning disaster, in fact relieved Spain of a perennial source of weakness and trouble, and left her free to set her own house in order. In this the task that faced the government at the outset of the 20th century was sufficiently formidable. Within the country the traditional antagonisms, regional, political, religious, still lived on, tending even to become more pronounced and to be complicated by the introduction of fresh elements of discord. The old separatist tendencies were increased by the widening gulf between the interests of the industrial north and those of the agricultural south. The growing disposition of the *bourgeois* and artisan classes, not in the large towns only, to imitate the "intellectuals" in desiring to live in closer touch with the rest of Europe as regards social, economic, scientific and political progress, embittered the struggle between the forces of Liberalism and those of Catholicism, powerfully entrenched in the affections of the women and the illiterate masses of the peasantry. To these causes of division were added others from without: the revolutionary forces of Socialism and Anarchism, here, as elsewhere, so far as the masses were concerned, less doctrines and ideals than rallying-cries of a proletariat in revolt against intolerable conditions. Finally, as though to render the task of patriotic Spaniards wellnigh hopeless, there was little evidence of any cessation of that purely factious spirit which in Spanish politics has ever rendered stable party government impossible. A sketch of the political history of a country is necessarily concerned with the externals of politics—the shifting balance of parties, changes of ministries, the elaboration of political programmes; and these have their importance. It must, however, not be forgotten that in a country in which, as in Spain, the constitutional consciousness of the mass of the people is very little developed, all these things reflect only very imperfectly the great underlying forces by which the life of the nation is being moulded and its destiny determined. For a century politics in Spain had been a game, played by professionals, between the "ins" and "outs"; victory or defeat at the polls depended less on any intelligent popular judgment on the questions at issue than on the passing interests of the "wire-pullers" and "bosses" (*Caciques*) who worked the electoral machinery.

Conflicting Tendencies.

Spanish Politics.

Silvela's Conservative cabinet was succeeded in March 1901 by a Liberal government under the veteran Sagasta, who remained in office—save for two short interludes—until the 3rd of December 1902. He was at once faced with two problems, very opposite in their nature, which were destined to play a very conspicuous part in Spanish politics. The first was that presented by the growth of the religious orders and congregations, the second that arising out of the spread of Socialism and industrial unrest. Under the concordat of the 20th of March 1851, by which the relations of Spain and the Vatican are still governed, the law under which since 1836 the religious congregations had been banished from Spain was so far relaxed as to permit the re-establishment of the orders of St Vincent de Paul, St Philip Neri and "one other among those approved by the Holy See," so that throughout the country the bishops "might have at their disposal a sufficient number of ministers and preachers for the purpose of missions in the villages of their dioceses, &c." In practice the phrase "one other" was interpreted by the bishops, not as one for the whole of Spain, but as one in each diocese, and at the request of the bishops congregations of all kinds established themselves in Spain, the number greatly increasing after the loss of the colonies and as a result of the measures of secularization in France.[1] The result was what is usual in such cases. The regular clergy were fashionable and attracted the money of the pious rich, until their wealth stood in scandalous contrast with the poverty of the secular clergy. They also all of them claimed, under the concordat, exemption from taxes; and, since many of them indulged in commercial and industrial pursuits, they competed unfairly with other traders and manufacturers, and tended to depress the labour market. The Law of Associations of the 30th of June 1887 had attempted to modify the evil by compelling all congregations to register their members, and all, except the three already recognized under the concordat, to apply for authorization. This law the congregations, hotbeds of reactionary tendencies, had ignored; and on the 19th of July 1901, the queen-regent issued a decree, countersigned by Sagasta, for enforcing its provisions.

Question of the Religious Orders.

Meanwhile, however, more pressing perils distracted the attention of the government. The industrial unrest, fomented by Socialist agitation, culminated in January 1902 in serious riots at Barcelona and Saragossa, and on the 16th of February in the proclamation of a general strike in the former city. The government sent General Weyler, of Cuban notoriety, to deal with the

Industrial Unrest and Socialist Agitation.

[1] See "Church and State in Spain." *The Times*, July 15, 1910.

situation; and order was restored. The methods by which this result had been achieved were the subject of violent attacks on the government in the Cortes, and on the 13th of March Sagasta resigned, but only to resume office five days later. He now returned to the question of the religious orders, and on the 9th of April issued a decree proclaiming his intention of enforcing that of the 19th of July 1901. The attitude of the Church was practically one of defiance. The nuncio, indeed, announced that the papacy would be prepared to discuss the question of authorization, but only on condition that all demands for such authorization should be granted. To avoid a crisis at the time when the young king was about to come of age, the government yielded; and on the 10th of May Sagasta announced that a *modus vivendi* with the Vatican had been established.

Enthronement of Alphonso XIII., 1902.

King Alphonso XIII., whose enthronement took place with all the antique ceremonial on the 17th of May, was himself at the outset under clerical and reactionary influences, and his contemptuous treatment of ministers—who at the ceremonial functions were placed wholly in the background—seemed to argue an intention of ruling personally under the advice of the court *camarilla*.[1] This impression, due doubtless to the king's extreme youth and inexperience, was belied in the event; but it served to discredit the Liberal government still further at the time. Señor Antonio Maura y Montanes, who proved himself later a statesman of exceptional character, seceded to the Conservatives. On the 7th of November Sagasta himself resigned, resumed office temporarily on the 14th, and handed in his final resignation on the 3rd of December. On the 6th of December a Conservative cabinet was formed under Señor Silvela, Señor Villaverde, pledged to a policy of retrenchment, taking the portfolio of finance.

Resignation and Death of Sagasta.

The death of Sagasta, on the 5th of January 1903, temporarily broke up the Liberal party, which could not agree on a leader; its counsels were directed for the time by a committee, consisting of Señors Montero Rios and Moret, the marquis de la Vega de Armijo, Señor Salvador and Count Romanones. The Republicans, under Salmeron, also had their troubles, due to the growing influence of Socialism; and, finally, the Conservatives were distracted by the rivalries between Silvela, Villaverde and Maura. In the country, meanwhile, the unrest continued. At Barcelona the university had to be closed to stop the revolutionary agitation of the students; in April there were serious riots at Salamanca, Barcelona and Madrid. The result of the new elections to the Cortes, declared on the 26th of April, revealed tendencies unfavourable to the government and even to the dynasty; the large towns returned 34 Republicans. A ministerial crisis followed; Maura resigned; and though the elections to the senate resulted in a large Conservative majority, and though in the lower house a vote of confidence was carried by 183 to 81, Silvela himself resigned shortly afterwards. Señor Villaverde was now called upon to form a cabinet. His government, however, accomplished little but the suppression of renewed troubles at Barcelona. His programme included drastic proposals for financial reform, which necessarily precluded an adventurous policy abroad or any additional expenditure on armaments, principles which necessarily brought him into conflict with the military and naval interests. On the 3rd of December Villaverde was forced to resign, his successor being Señor Maura. Meanwhile, on the 24th of November, the Liberal party had been reconstructed, as the Democratic party, under Señor Montero Rios.

Break-up of Parties.

Villaverde Ministry, 1904.

Señor Maura, as was to be proved by his second administration, represented the spirit of compromise and of conservative reform. His position now was one of singular difficulty. Though a Catholic, he had to struggle against the clerical *coterie* that surrounded the king, and had not influence enough to prevent the appointment of Monsignor Nozaleda, formerly archbishop of Manila and a prelate of notoriously reactionary views, to the important see of Valencia. His concessions to the demands of the ministers of war and marine for additional estimates for the army and navy exposed him to the attacks of Villaverde in the Cortes; and still fiercer criticism was provoked by the measure, laid by him before the Cortes on the 23rd of June, for the revision of the concordat with Rome, and more especially by the proposal to raise a loan at 4% to indemnify the religious orders for their estates confiscated during the Revolution. Violent scenes greeted the attempt of the government to procure the suspension of the parliamentary immunities of 140 deputies, accused or suspected of more or less treasonable practices, and when, on the 4th of October, the Cortes reopened after the summer recess, Señor Romero Robledo, the president of the lower house, opened an attack on the ministry for their attempted breach of its privileges. Furious debates followed on this, and on the subject of Maura's financial proposals, which were attacked by the Conservative Villaverde and the Liberal Moret with impartial heat. On the 14th of December Maura resigned an impossible task and King Alphonso made General Azcarraga head of a narrowly Clerical-Conservative cabinet.

First Maura Ministry, 1904.

Azcarraga Ministry.

[1] *Ann. Register* (1902), p. 347.

The new ministry, confronted by a rapidly spreading revolutionary agitation and by a rising provoked by a crop failure and famine in Andalusia, survived scarcely a month. On the 26th of January 1905 Azcarraga resigned, and two days later Señor Villaverde once more became prime minister. He was in no hurry to summon the Cortes, partly because the elections to the provincial councils were due in March, and these had to be manipulated so as to ensure the return of a Senate of the right colour, partly because the convocation of the Cortes seemed at best a necessary evil. Already the discredit of parliamentary government was being evidenced in the increased personal power of the young king. Alphonso was now shaking himself loose from the deadening influence of the reactionary court, and was beginning to display a disconcerting interest in affairs, information about which he was apt to seek at first hand. The resignation of the see of Valencia by Archbishop Nozaleda was a symptom of the new spirit. This was none the less distasteful to the Republicans, who thundered against personal government, and to the Liberals, who clamoured for the Cortes and the budget. The Cortes met at last on the 14th of June, and the upshot justified Villaverde's reluctance to meet it. Attacked by Maura and Moret alike, the prime minister (June 20) accused his former colleague of acting through personal pique; on a motion of confidence, however, he was defeated by 204 votes to 54, and resigned. He died on the 15th of July following, within a few weeks of his former leader and colleague Silvela.

Villaverde Ministry, 1905.

The Liberals now once more came into power under Señor E. Montero Rios, Señor Moret having refused the premiership. The government programme, announced with a view to influencing the impending elections, included financial reform, reform of the customs, modification of the *octroi*, and the question of the concordat with Rome. The result of the elections was a substantial Liberal majority in both houses. The government was none the less weak. Quarrels broke out in the cabinet between Señor José Echeray, the distinguished banker and famous dramatist, who as minister of finance was intent on retrenchment, and General Weyler, who as minister of war objected to any starving of the army. On the 27th of October, scarcely a fortnight after the opening of the session, the government resigned. At the instance of the king, who was going abroad, Señor Montero Rios consented indeed to resume office; but his difficulties only increased. The price of corn rose, owing to the reimposition by the government, before the elections, of the import duties on corn and flour; and in November there was serious rioting in Seville, Granada, Oviedo, Bilbao and Valencia, while in Catalonia the Separatist movement gathered such force that on the 29th martial law was proclaimed throughout the province. The same day the government finally resigned. Señor Moret now accepted the

Montero Rios Ministry, 1905.

Moret Ministry.

premiership; he took over Señor Echeray's budget, while General Weyler was replaced at the war office by General Luque.

The great constitutional parties had broken up into quarrelling groups just at the time when, as it seemed, the parties of reaction were concentrating their forces. Not the least ominous symptom was the attitude of the officers, who, irritated by newspaper attacks on their conduct in Catalonia more especially, demanded that all crimes against the army should be tried by the councils of war. The prolonged controversies to which this gave rise were settled on the 18th of March by a compromise passed by the Cortes; under this act all cases of press attacks on officers were to be tried by the courts martial, while those against the army generally and the national flag were still to be reserved for the civil courts. The singular weakness of the government revealed by this abdication of part of the essential functions of the civil power would have led to its speedy downfall, but for the truce cried during the festivities connected with the marriage of the king with Princess Victoria Eugénie Ena of Battenberg, which took place on the 31st of May.

Alphonso XIII.

The king's marriage was in many respects significant. In spite of the young queen's "conversion" and the singular distinction conferred on her by the papal gift of the golden rose, the "Protestant" alliance marked a further stage in Alphonso XIII.'s emancipation from the tutelage of the Clerical-Conservative court. He was, indeed, increasingly displaying a tendency to think and act for himself which, though never over-stepping the bounds of the constitution, was somewhat disconcerting to all parties. His personal popularity, too, due partly to his youth and genial manners, was at this time greatly increased by the cool courage he had shown after the dastardly bomb attack made upon him and his young wife, during the wedding procession at Madrid, by the anarchist Matteo Morales.[1] Whatever his qualities, the growing entanglement of parliamentary affairs was soon to put them to the test. For the coronation was hardly over when Señor Moret resigned,

Lopez-Dominguez Ministry, 1906.

and on the 6th of July Captain-General Lopez-Dominguez became head of a cabinet with a frankly anti-clerical programme, including complete liberty of worship, the secularization of education, and the drastic regulation of the right of association. The signature by the king of an ordinance giving legal validity to the civil

Civil Marriage Question.

marriages of Catholics aroused a furious agitation among the clergy, to which bounds were only set by the threat of the government to prosecute the bishop of Tuy and the chapter of Cordova. In the session 1906–1907 the most burning subject of debate was the new Associations Law, drawn up by Señor Davila. Even in the Liberal ranks the question aroused furious differences of opinion; Señor Montero Rios, the president of the senate, denounced the "infamous attacks on the church"; the government itself showed a wavering temper in entering on long and futile negotiations with the Vatican; while in January 1907 the cardinal archbishop of Toledo presented a united protest of the Spanish episcopate against the proposed law. This and other issues produced complete disunion in the Liberal party. Already, on the 27th of November, Lopez-Dominguez had resigned; his

Vega de Armijo Ministry, 1906–1907.

successor, Moret, had at once suffered defeat in the house and been succeeded in his turn, on the 4th of December, by marquis de la Vega de Armijo. The question was now mooted in the cabinet of dropping the Associations Law; but on the 21st of January Señor Canalejas, president of the lower house, who was credited with having inspired the bill, publicly declared that in that event he would cease to support the government. By the 24th the cabinet had resigned, and a Conservative government was in office under Señor Maura as premier.

The administration of Señor Maura, which lasted till the 21st of October 1900 marks an important epoch in the history of modern Spain. The new premier was no mere party politician, but a statesman who saw the need of his country, on the one hand for effective government, on the other hand for education, so as to enable it ultimately to govern itself. Though a sincere Catholic, he was no Clerical, as was proved by his refusal to withdraw the ordinance on civil marriage. The main objects that he set before himself were, firstly, the maintenance of order; secondly, the reform of local government, so as to destroy the power of the *Caciques* and educate the people in their privileges and responsibilities. The dissolution of the Cortes produced a certain rearrangement of parties. The Liberal groups, as usual when in opposition, coalesced. The Republicans, on the other hand, split into sections; in Barcelona, Tarragona and Gerona they were Separatists, while a new party appeared under the name of Solidarists, consisting of Separatists, Carlists and Socialists. The elections in April resulted in a sweeping Conservative victory—the government secured a majority in the lower house of 88 over all other groups combined. As for the "dynastic opposition," it was reduced to a rump of 66 members, a result so unsatisfactory from the point of view of the monarchy that the government offered to quash certain Conservative returns in order to provide it with more seats. The dynastic opposition, however, considered that it had been unfairly dealt with in the conduct of the elections; and though, out of consideration for the dynasty (an heir to the throne having been born on the 10th of May), they attended the opening of the Cortes on the 13th of May, the Liberals refused to take part in the session that followed, which lasted till the 29th of July. When, however, the Cortes reopened on the 10th of October, the dynastic opposition was once more in its place. It was now that Señor Maura brought in his Local Administration Bill, a measure containing 429 clauses, the main features of which were that it largely increased the responsibility of the local elected bodies, made it compulsory for every elector to vote, and did away with official interference at the polls. The bill met with strenuous opposition, and on the 23rd of December 1907 the Cortes adjourned without its having been advanced.

Second Maura Administration, 1907.

Local Administration Reform.

At the close of the year an Anarchist outrage gave the excuse for the proclamation of martial law in Barcelona, and after the opening of the new session of the Cortes (January 23, 1908) a bill was introduced into the senate giving to the government the most drastic powers for the suppression of Anarchism. Its provisions practically amounted to a complete suspension of the guarantees for civil liberty, it met with the most strenuous opposition, and its final passing by the Senate (May 9) was followed by a serious crisis. Two months before (March 10–13) King Alphonso, with characteristic courage, had paid a surprise visit to Barcelona, and the general enthusiasm of his reception seemed to prove that the disaffection was less widespread or deep than had been supposed. In the circumstances, Señor Maura dropped the Suppression Bill, and the king issued an ordinance re-establishing constitutional guarantees in Catalonia.

This good feeling was unfortunately not destined to be of long duration; and in the following year the struggle between the antagonistic forces in Spain once more produced a perilous crisis. The Local Administration Bill, after being debated for two sessions, passed the lower house on the 13th of February 1909, having at the last moment received the support of the Liberal Señor Moret, though the Radicals as a whole opposed it as gratifying to Señor Cambò, the Regionalist leader, and therefore as tending to disintegration. Though ruling in the spirit of an enlightened despotism rather than in that of a constitutional government, Señor Maura had succeeded in doing a notable work for Spain. It was inevitable that in doing so he should incur unpopularity in many quarters. His efforts to reconstruct the Spanish navy were attacked both by the apostles of retrenchment and by those who saw in the shipbuilding contracts an undue favouring of the foreigner; the Marine Industries Protection Act was denounced as favouring the large shipowners and exporters at the expense of the smaller men; the

[1] The king's reckless daring was destined later to impair his popularity, for in an enthusiastic motorist blind courage is a quality apt to be exercised at the expense of others.

Compulsory Education Act as "a criminal assault on the rights of the family." His ecclesiastical policy also exposed him to the fate of those who take the middle way; the Liberals denounced the minister of education, Don F. Rodriguez San Pedro, for making concessions to the teaching orders, while the archbishops of Burgos and Santiago de Compostella fulminated against the government for daring to tax the congregations. In his reforming work Señor Maura had an active and efficient lieutenant in the minister of the interior, Señor La Cierva. Under his auspices laws were passed reforming and strengthening the police force, instituting industrial tribunals, regulating the work of women and children, introducing Sunday rest, early closing, and other reforms. In short, the government, whatever criticism might be levelled at its methods, had accomplished a notable work, and when on the 6th of June 1909 the Cortes adjourned, its position seemed to be assured.

Morocco Crisis. Its downfall was ultimately due to the development of the crisis in Morocco. This is described elsewhere (see MOROCCO: *History*); here it is only proposed to outline the effects of its reaction upon the internal affairs of Spain. The trouble, long brewing, broke out in July, with the attack by the Riff tribesmen upon the workmen engaged on the railway being built to connect Melilla with the mines in the hills, held by Spanish *concessionaires*. The necessity for strengthening the Spanish forces in Africa had for some time been apparent; but Señor Maura had not dared to face the Cortes with a demand for the necessary estimates, for which, now that the crisis had become acute, he had to rely on the authorization of the council of state. The spark was put to the powder by the action of the war minister, General Linares, in proposing to organize a new field force by calling out the Catalan reserves. This summoned up too vivid memories of the useless miseries of former over-sea expeditions. On the 26th of July a general strike was proclaimed at Barcelona, and a movement directed at first against the "conscription" rapidly developed into a revolutionary attack on the established order in church and state.

Barcelona Rising of July 1909. The city, a *colluvies gentium*, was seething with dangerous elements, its native proletariat being reinforced by emigrants returned embittered from failure in South America and a cosmopolitan company of refugees from justice in other lands. The mob, directed by the revolutionary elements, attacked more especially the convents and churches. From the city the revolutionary movement spread to the whole province. In Barcelona the rising was suppressed after three days' street fighting (July 27-29). On the 28th martial law was proclaimed throughout Spain; and now began a military reign of terror, which lasted until the end of September. In the fortress of Monjuich in Barcelona were collected, not only rioters caught red-handed, but many others—notably journalists—whose opinions were obnoxious. The greatest sensation was caused by the arrest, on the 31st of August, of Señor Ferrer, a theoretical anarchist well known in many countries for his anti-clerical educational work and in Spain especially as the founder of the "lay schools." He was accused of being the chief instigator of the Barcelona rising, was tried by court martial (Oct. 11-13), and shot. This tragedy, which rightly or wrongly aroused the most widespread indignation throughout Europe, produced a ministerial crisis in Spain. The opening of the October session of the Cortes was signalized by a furious attack by Señor Moret on Señores Maura and La Cierva, who were accused of having

Fall of Maura. sacrificed Ferrer to the resentment of their clerical task-masters. The government had been already weakened by the news of Marshal Marina's reverse in Morocco (Sept. 30); to this new attack it succumbed, Señor Maura resigning on the 21st of October 1909.

Moret Ministry, 1909-1910. On the 22nd the formation of a new cabinet under Señor Moret was announced. It was from the first in a position of singular weakness, without a homogeneous majority in the Cortes, and depending for its very existence on the uncertain support of the extreme Left and the Republicans. For three months it existed without daring to put forward a programme. It sent General Weyler to keep Barcelona in order, caused the release of most of the prisoners in Monjuich, reduced the forces in Morocco, reopened negotiations with Rome for a modification of the concordat, and on the 31st of December, the end of the financial year, was responsible for the issue of a royal decree stating that the budget would remain in force until the Cortes could pass a new one. But, meanwhile, the municipal elections, under the new Local Administration Law, had resulted in a triumph of the Liberals (Dec. 12). Señor Moret now considered the time ripe for a dissolution; the king, however, refused to consent, and on the 9th of February 1910 the ministry resigned. The new cabinet, with Señor Canalejas as president of the council, included members of the various Liberal and Radical groups: Garcia Prieto (foreign affairs), Count Sagasta (interior), General Aznar (war), the Democrat Arias Miranda (navy), Cobian, a strong Catholic though a Liberal (finance), Ruiz Valarino, a Democrat (justice), Calbeton (public works) and Count Romanones, who advocated a liberal settlement with the Church (education).

Canalejas Ministry, 1910.

Quarrel with the Vatican. Though at once denounced by Señor Moret as "a democratic flag being used to cover reactionary merchandise,"[1] the name of Canalejas was in itself a guarantee that the burning question of the relations of the state to Rome and the religious orders would at last be taken in hand, while the presence of so many moderate elements in his cabinet showed that it would be approached in a conciliatory spirit. A beginning was made with the issue of a circular by the minister of finance (March 18), ordering the collection of taxes from all religious bodies carrying on commercial and industrial enterprises. What more could be done would depend on the result of the elections necessitated by the dissolution of the Cortes on the 15th of April. Count Romanones, desiring to educate the electors, had been busy establishing schools; but the sweeping victory of the Liberals at the polls[2] was probably far more due to the fact that this was the first election held under Señor Maura's Local Administration Act, and that the ignorant electors, indignant at being forced to vote under penalty of a fine, where they did not spoil their ballot papers, voted against the Conservatives as the authors of their grievance.

The government was thus in a position vigorously to pursue its religious policy. On the 31st of May the official *Gaceta* published a decree setting forth the rules to which the religious associations would have to submit. It was pointed out that, in conformity with the decree of the 9th of April 1902, it had become necessary to coerce those congregations and associations which had not fulfilled the formalities prescribed by the law of 1887, and also those engaged in commerce and industry which had not taken out patents with a view to their taxation. It further ordered that all foreign members of congregations were to register themselves at their respective consulates, in accordance with the decrees of 1901 and 1902. On the 11th of June a further and still more significant step was taken. A royal ordinance was issued repealing that signed by Canovas del Castillo (Oct. 23, 1876), immediately after the promulgation of the constitution of 1876, interpreting the 11th article of the constitution, by which the free exercise of all cults was guaranteed in Spain. The article in question forbade "external signs or public manifestations of all religious confessions with the exception of that of the state," which was defined by Canovas del Castillo as meaning "any emblem, attribute or lettering which would appear on the exterior walls of dissident places of worship."[3] In the speech from the throne at the opening of the new Cortes (June 16) the king declared that his government would "strive to give expression to the

[2] The composition of the new parliament was as follows—Senate: Ministerialists, 103; Conservatives, 42; Regionalists, 5; Republicans, 4; Carlists, 3; miscellaneous groups, 11. **Lower House**: Ministerialists, 227; Conservatives, 105; Republicans, 42; Carlists, 9; Catalans, 7; Integrists, 2; Independents, 9; unattached, 3.

[3] *The Times* (June 13, 1910).

public aspirations for the reduction and control of the excessive number of orders and religious orders, without impairing their independence in spiritual matters," and in introducing a bill for the amendment of the law of 1887 Señor Canalejas declared that the government, "inspired by the universal spirit of liberty of conscience," had given to article xi. of the constitution "the full sense of its text."[1]

"Liberty of conscience," a principle condemned by the Syllabus of 1864 and sneered at in the encyclical *Pascendi gregis* of 1905, was hardly a phrase calculated to conciliate the Spanish clergy, still less the Vatican. A cry went up that to allow dissident churches to announce their presence was to insult and persecute the Catholic Church;[2] at Rome the decree was attacked as unconstitutional, and a breach of diplomatic propriety all the more reprehensible as negotiations for a revision of the concordat were actually pending. A violent clerical agitation, encouraged by the Vatican, was started, 72 Spanish archbishops and bishops presenting a joint protest to the government. Fuel was added to the fire by the introduction of a bill—known as the Cadenas bill—forbidding the settlement of further congregations in Spain until the negotiations with the Vatican should have been completed. This was denounced at Rome as a unilateral assertion on the part of the Spanish government of an authority which, under the concordat, belonged to the Holy See as well. As a preliminary to negotiation, the government was required to rescind all the obnoxious measures. This demand broke the patience of the prime minister, and on the 30th of July Señor de Ojeda, Spanish ambassador at the Vatican, was instructed to hand in his papers. In Vatican circles dark hints began to be dropped of a possible *rapprochement* with Don Jaime, who had succeeded his father Don Carlos, on the 18th of July 1909, as the representative of Spanish legitimacy and Catholic orthodoxy. The pretender, indeed, disclaimed any intention of stirring up civil war in Spain; his mission would be to restore order when the country should have wearied of the republican régime whose speedy advent he foresaw. The fulfilment of the first part of this prophecy seemed to some to be brought a step nearer by the overthrow of the monarchy in Portugal on the 5th of October 1910. For Spain its immediate effect was to threaten a great increase of the difficulties of the government, by the immigration of the whole mass of religious congregations expelled from Portugal by one of the first acts of the new régime.

(W. A. P.)

CHRONOLOGICAL TABLES OF CHRISTIAN DYNASTIES IN SPAIN.

Kings of the Visigoths, having relations with Spain, but not established within it:—

Ataulf	410–415	Entered the north-east of Spain, murdered at Barcelona.
Sigeric	415	His murderer, promptly murdered in turn.
Wallia	415–419	Elected king, was the ally (foederatus) of the empire. Defeated the Vandals and Alans. Migrated to south-west of France with all his people.
Theodoric I.	419–451	Made inroads into Spain, as ally of the empire. Killed in the battle with Attila.
Thorismund	451–453	All these kings had the seat of their government north of the Pyrenees. They made inroads in Spain and had a stronghold on the north-east. Alaric was killed by the Frankish king, Clovis, at Vouillé, 507.
Theodoric II.	453–466	
Euric	466–485	
Alaric II.	485–507	
Gesalic	507–511	Bastard son of Alaric, was murdered.
Amalaric	507–531	Reigned in south and south-east of France under protection of Theodoric, the Ostrogothic king in Italy. Fled before Franks to Barcelona at end of reign, and was murdered at Barcelona.

Kings of the Visigoths established in Spain:—

Theudis	531–548	An Ostrogoth, general of Theodoric. Murdered Amalaric, and was murdered in turn at Seville by Theudigesil.
Theudigisel	548–549	Murdered by Agila.
Agila	549–554	Murdered at Mérida.
Athanagild	554–567	Rebelled against Agila, evacuated Andalusia to secure aid of Imperial officers. Established the capital at Toledo.
Liuva I.	567–572	Elected at Narbonne. Associated his brother Leovigild with himself.
Leovigild	567–586	The first Visigoth king who assumed the diadem and purple, struck coins in his own name, and enforced recognition of his supremacy in all parts of Spain, except the south coast.
Reccared	586–601	Son. Associated with his father. The first Visigoth king who was a Catholic.
Liuva II.	601–603	Son. Soon murdered.
Witteric	603–610	Leader of Arian reaction.
Gunthemar	610–612	Obscure kings.
Sisebut	612–620	
Reccared II.	620–621	
Swintella	621–631	Associated his family with him on the throne. They were all deposed by the nobles.
Reccimer	621–631	
Sisinand	631–636	These kings were mainly supported by the clergy, and were engaged in endeavouring to make the crown hereditary, by associating their kinsmen with themselves.
Chintila	636–640	
Tulga	640–641	
Chindaswinth	641–652	
Recceswinth	649–672	
Wamba	672–680	Unrelated to his predecessor and elected by the nobles—was deposed and tonsured.
Erwic	680–687	The most obscure of the Visigoth kings. Egica and Witiza appear to have continued the struggle with the nobles, by whom Roderic was tumultuously elected, in opposition to Witiza's son Actula.
Egica	687–701	
Witiza	697–710	
Roderic	710–711	

Early kings of the Christian north-west of Spain, of uncertain chronology and relationship:—

Pelayo	718–737	Elected as "king of the Goths."
Favila	737–739	Brother of Pelayo.
Alphonso I.	739–757	Son-in-law of Pelayo.
Froila	757–768	Son of Alphonso I. Murdered by his brother.
Aurelio	768–774	Brother or cousin.
Silon	774–785	Brother-in-law of Aurelio.
Maurecat	785–789	Bastard son of Alphonso I.
Bermudo	789–792	Called the Deacon, descendant of Alphonso I., reigned for a very short time, and retired to a religious house.
Alphonso II.	792–842	Called the Chaste, son of Froila. Was perhaps chosen in opposition to Bermudo.
Ramiro I.	842–850	Son of Bermudo the Deacon.
Ordoño I.	850–866	Son of Ramiro.
Alphonso III.	866–914	Son of Ordoño.

Period of the small kingdoms, unions, separations and reunions; the sons of Alphonso III. having rebelled, and forced a division of the kingdom near the close of the king's reign:—

Garcia . .	910–913	Took Leon, which then included Bardulia, or Castile, as the eldest son.
Ordoño II. . .	913–923	Second son; became king in Gallicia which included northern Portugal and acquired Leon on the death of his brother Garcia.
Fruela . . .	923–924	Third brother; held Asturias, and was king of all north-west for a short time after death of Ordoño.
Alphonso IV. .	924–931	Son of Ordoño; became a monk at Sahagun, and was succeeded by his brother Ramiro.
Ramiro II. . .	931–950	In his reign Castile broke away from Leon, under the count Fernan Gonzales.
Ordoño III. .	950–955	Son of Ramiro.
Sancho I., "The Fat."	955–967	Half brother of Ordoño III. and son of Ramiro II. by his second marriage with a daughter of Sancho Abarca of Navarre. Was driven out by his nobles, in alliance with Fernan Gonzales, count of Castile, and restored by the caliph. The rebels put Ordoño, son of Alphonso IV., on the throne for a time.
Ramiro III. .	967–982	Son of Sancho. Succeeded as a boy. His reign was a period of anarchy.
Bermudo II., "The Gouty"	982–999	Son of Ordoño III., was supported against his cousin Ramiro III. by the nobles, and was placed on the throne by the Hajib Mansur.
Alphonso V. .	999–1027	Son of Bermudo. Began the restoration of the kingdom after the period of anarchy, and subjection to the caliphate. Killed at siege of Viseu.
Bermudo III. .	1027–1037	Son of Alphonso V.; was killed in battle at Tamaron with his brother-in-law Ferdinand, count and then first king of Castile.
Fernando I., or Ferdinand.	1027–1065	Son of Sancho el Mayor of Navarre, king of Castile by right of his mother, and of Leon and Gallicia by the sword.

Counts of Castile

The counts of Castile began, as a body, and not as a line of chiefs, in the reign of Alphonso the Chaste (789–842). They strove for independence from the first, and when one count had replaced several they achieved it.

Fernan Gonzales	923–968	Made himself independent of Leon. One of his daughters married Ordoño III. of Leon. By a second marriage with a daughter of Sancho Abarca of Navarre he had a son and successor.
Garcia Fernandez	968–1006	Son.
Sancho Garcia .	1006–1028	Son.
Garcia . . .	1028	Murdered. Castile then passed to Garcia's sister, the wife of Sancho el Mayor of Navarre.

Early Kings of Navarre

The early history of Navarre has been overlaid with fable, and with pure falsification, largely the work of the Benedictines of San Juan de la Peña near Huesca. Their object was to prove the foundation of their house by a king of Navarre, Aragon and Sobrarbe, in the 9th century. They were helped by the patriotism of the Aragonese, who wished to give their kingdom an antiquity equal to that of Leon. Hence much pure invention, bolstered up by forgery of charters, falsification of genuine ones, and construction of imaginary pedigrees.

Sancho Abarca, *i.e.* Brogues	906–926	Made himself independent king at Pamplona. He fought with the Carolingian counts of the marches, and in alliance with the Spanish Mahommedan Beni Casi of Saragossa.
Garcia Sanchez . Sancho Garcia . Garcia Sanchez "The Trembler"	926–966 966–993 993–1000	Very obscure. The most undoubted personality of the time is Tota (Theuda), widow of Sancho Abarca, who governed for her son and whose daughters were married to the kings of Leon and counts of Castile.
Sancho el Mayor	1000–1035	Son of "The Trembler." He married a daughter of Sancho Garcia, count of Castile. On the murder of Garcia, the last count, he took Castile by right of his wife. He inherited, or acquired, superiority over the central Pyrenean regions of Aragon and Sobrarbe. He divided his various dominions—Navarre to Garcia, Castile to Fernando, Sobrarbe to Gonzalo, and Aragon to Ramiro Sanchez, a natural son.
Garcia III. . .	1035–1054	Killed in battle with his brother Fernando of Castile and Leon at Atapuerca.
Sancho IV. . .	1054–1076	Son. Murdered by his natural brother Ramon at Peñalen. The Navarrese then chose Sancho Ramirez of Aragon as king. The kingdoms remained united till 1134.

Historic kingdom of Aragon:—

Ramiro Sanchez	1035–1067	Natural son of Sancho el Mayor of Navarre, who on the death of his legitimate brother Gonzalo, annexed Sobrarbe. The kingdom of Sobrarbe lasted only during the life of Gonzalo.
Sancho I. . .	1067–1094	Son of Ramiro. Was killed while besieging Huesca.
Pedro I. . . .	1094–1102	Son of Sancho.
Alphonso I. "The Battler."	1102–1134	Second son of Sancho. He took Saragossa from the Moors, and was married to Urraca, queen of Castile and Leon.
Ramiro II. . .	1134–1137	Third son of Sancho. A monk, who was exclaustrated after the death of Alphonso, but returned to the cloister on the birth of his daughter Petronilla.
Petronilla . .	1137–1164	Married to Ramon Berenguer, count of Barcelona, who became king by right of his wife.

The Early Counts of Barcelona

In the last years of the 8th and beginning of the 9th century, Charlemagne and Louis the Pius began conquering the north-east of Spain, which the Arabs had occupied as early as 713. By 811 the Franks had conquered as far as Tortosa and Tarragona. The territory gained was called the Marca Hispanica, and was governed by counts of Roussillon, Ampurias, Besaltu, Barcelona, Cerdeña, Pallars and Urgell. They became independent during the decadence of the Carolingians. The supremacy was acquired gradually by the counts of Barcelona who became independent with Wilfred I. by 874. He and his immediate descendants gradually subdued the other counts. They suffered much from the inroads of Mansur in the 10th century, but on the decline of the caliphate, they took part in the general advance.

Berenguer Ramon I.	1018–1035	Held Barcelona, Vich and Manresa with land conquered from the Moors to the south.
Ramon Berenguer, "The Old."	1035–1076	Son. His father had divided his possessions between his widow and all his sons, but Ramon Berenguer reunited them by force. He left his dominion to be held in common by his two sons.
Ramon Berenguer II. and Berenguer Ramon II.	1076–1082 1076–1082	Ramon Berenguer II. Cap d'estops ("Tow Pow") was murdered by Berenguer Ramon II., whose end is unknown.
Ramon Berenguer	1082–1131	Son of Ramon Berenguer II. By his marriage with Aldonza or Douce of Provence he acquired territory in south-eastern France. He inherited or subdued all the other countships of Catalonia, except Peralada.
Ramon Berenguer	1131–1162	Son. Inherited the Spanish possessions of his father, the French going to a brother. Was betrothed to Petronilla of Aragon, and married her in 1150, becoming king of Aragon.

Second period of the union, disunion and reunion of Castile and Leon from Fernando I. to Fernando III. Fernando I. divided his dominions among his three sons: to Sancho, the eldest, Castile; to Alfonso, the second son, Leon; to Garcia, the third son, Gallicia.

Sancho II.	1065–1072	He expelled Alphonso and Garcia, reuniting the three kingdoms. Murdered at Zamora.
Alphonso VI.	1065–1109	Returned from exile, obtained all the three kingdoms, and imprisoned Garcia for life.
Urraca	1109–1126	Daughter of Alphonso VI., and widow of Raymond of Burgundy.
Alphonso VII.	1126–1157	Son. Recognized as king in Gallicia during his mother's life. Divided his kingdoms between his sons; to the elder Sancho, Castile, to the younger, Fernando, Leon.
Sancho III.	1157–1158	In Castile.
Fernando II.	1157–1188	In Leon.
Alphonso VIII.	1158–1214	Castile. Son of Sancho III.
Alphonso IX.	1188–1230	Leon. Son of Fernando II. Is numbered IX. because he was junior to the cousin Alphonso of Castile.
Henry I.	1214–1217	Castile. Son of Alphonso VIII.
Berengaria	1217–	Daughter of Alphonso VIII. Married to Alphonso IX. of Leon, but the marriage was declared uncanonical by the pope. The children were declared legitimate. Berengaria resigned the crown of Castile to her son Fernando by the uncanonical marriage with Alphonso IX. of Leon.
Fernando III.	1217–1252	Inherited Leon on the death of his father Alphonso IX., and united the crowns for the last time, in 1230.

Castile and Leon till the Union With Aragon.

Fernando III. was king of Castile and Leon from 1230 to 1252.

Alphonso X.	1252–1284	Eldest son of Fernando III.
Sancho IV.	1284–1295	Second son of Alphonso X. Was preferred to the sons of his elder brother Ferdinand de la Cerda, who died in Alphonso's lifetime.
Ferdinand IV.	1295–1312	Son of Sancho.
Alphonso XI.	1312–1350	Son of Ferdinand IV.
Peter "The Cruel"	1350–1369	Son of Alphonso XI.
Henry II.	1369–1379	Natural son of Alphonso IX. He deposed and murdered Peter, and founded the line of the new kings.
John I.	1379–1390	Son of Henry II.
Henry III.	1390–1406	Son of John I.
John II.	1406–1454	Son of Henry III.
Henry IV. Isabella	1454–1474 1474–1504	Son. The legitimacy of the daughter of his second marriage was not recognized, and the crown of Castile passed to his sister, who married Ferdinand of Aragon. The marriage united the crowns in 1479.

Aragon, from the union with the county of Barcelona, to the union with Castile:—

Alphonso II.	1162–1196	Son and successor of Petronilla and Ramon Berenguer IV. Recovered the Provençal possessions of Ramon Berenguer II.
Peter II.	1196–1213	Son. Killed at Muret.
James I., "The Conqueror."	1213–1276	Son. Conquered the Balearic Islands and Valencia. Left the islands to his son James, from whom the title passed in succession to Sancho (d. 1324), his eldest son, to Sancho's nephew James (d. 1349), and to another James, his son (d. 1375); but the actual possession was recovered by the elder line before the extinction of the younger branch.
Peter III.	1276–1285	Eldest son. Conquered Sicily, claimed by right of his wife Constance, daughter of Manfred of Beneventum.
Alphonso III.	1285–1291	Eldest son. Succeeded to Spanish possessions.
James II.	1291–1327	Second son of Peter III. He had succeeded to Sicily, but resigned his rights, which were then assumed by his brother Frederick, who founded the Aragonese line of kings of Sicily.
Alphonso IV.	1327–1336	Son of James II.
Peter IV.	1336–1387	Finally reannexed the Balearic Islands.
John I.	1387–1395	Son by the marriage of Peter IV. with his cousin Eleanor of the Sicilian line.
Martin	1395–1410	Younger brother of John I. His son Martin was chosen king of Sicily, but died in 1409. The male line of the kings of Aragon of the House of Barcelona ended with Martin.
Ferdinand I.	1412–1416	Second son of Eleanor, sister of Martin, and wife of John I. of Castile. Succeeded by choice of the Cortes.
Alphonso V.	1416–1458	Son. Spent most of his life in Italy, where he was king of Naples and Sicily.
John II.	1458–1479	Brother of Alphonso V., whom he succeeded in the Spanish possessions, and Sicily, but not in Naples.
Ferdinand II.	1479–1516	Son. His marriage with Isabella united the crowns.

Navarre till the conquest of Ferdinand the Catholic: —

Garcia IV.	1134–1150	A descendant of Sancho el Mayor. Elected by the Navarrese on the death of Alphonso of Aragon without issue.
Sancho VI., called "The Wise"	1150–1194	Son. Father of Berengaria, wife of Richard Cœur de Lion.
Sancho VII.	1194–1234	Son. Died without issue.
Theobald I.	1234–1253	Husband of Blanche, daughter of Sancho "The Wise."
Theobald II.	1253–1270	Son. Died without issue.
Henry I.	1270–1274	Brother.
Jeanne I.	1274–1305	Daughter, wife of Philip IV. of France. Navarre was now absorbed in France, and so remained till 1328, when on the death of Charles IV. of France, the last of the house of Hugh Capet, it passed to his niece Jeanne, daughter of Louis X., and wife of Philip, count of Evreux.
Jeanne II.	1328–1349	
Charles II., called "The Bad"	1349–1387	Son. These two kings were much concerned with France, and little with Spain.
Charles III., "The Noble"	1387–1425	
John I. of Aragon	1425–1479	King of Navarre by right of his wife Blanche, daughter of Charles III. On his death Navarre passed to his daughter by Blanche, Eleanor, widow of Gaston IV., count of Foix. She died in the same year as her father, and Navarre passed to her grandson, Francis Phoebus.
Francis Phoebus	1479–1483	Died without issue, and was succeeded by his sister, the wife of Jean D'Albret. The Spanish part of Navarre was conquered by Ferdinand the Catholic in 1512.
Catherine	1483–1514	

Kings of United Spain

Joan, "The Mad"	1504–1520	Daughter of Isabella, whom she succeeded in Castile, with her husband Philip I., of Habsburg. After his death, her father Ferdinand was guardian and regent.
Charles I. in Spain	1516–1556	Son of Joan. Was recognized as king with his mother; elected to the empire as Charles V.
Philip II.	1556–1598	Son. Succeeded on abdication of Charles V.
Philip III.	1598–1621	Son.
Philip IV.	1621–1665	Son.
Charles II.	1665–1700	Son. Died without issue.
Philip V.	1700–1746	Succeeded by the will of Charles II., as grandson of Maria Teresa, daughter of Philip IV., and of Louis XIV., king of France. With him began the line of the Spanish Bourbons. He abdicated for a few months in 1724–1725 in favour of his son Louis, but resumed the crown when Louis died.
Ferdinand VI.	1746–1759	Son by Philip V.'s first marriage with Maria Louisa of Savoy. Died without issue.
Charles III.	1759–1788	Brother. Son of Philip V. by his second marriage with Elizabeth Farnese.
Charles IV.	1788–1808	Son. He abdicated under pressure in 1808 in favour of his son Ferdinand, and then resigned his rights to Napoleon.

Kings of United Spain (*continued*)

Ferdinand VII.	1808–1833	Was proclaimed king on the forced abdication of his father. Remained a prisoner in France during the Peninsular War. He repealed the Salic Law established by Philip V.
Isabella II.	1833–1868	Daughter. Her succession was resisted by her uncle Don Carlos, and the Carlist Wars ensued. Deposed.
Alphonso XII.	1875–1885	Son. His mother abdicated in his favour and he was restored.
Alphonso XIII.	1886–	Born after his father's death.

(D. H.)

Bibliography.—(1) *Sources*: There are several published collections of sources for Spanish history. Of these the oldest is R. Belus, *Rerum hispanicarum scriptores aliquot in bibliotheca Roberti Beli* . . . 3 vols. fol. (Frankfort, 1579–1581). In 1740–1752 was published at Madrid J. A. de Creu y Bertodano's *Coleccion de los tratados de paz, alianza, neutralidad, garanzia, proteccion, treguia y mediacion, &c., que han hecho los reyes de España con los pueblos, republicas y demas potencias y otras partes del mondo*, in 12 vols. folio. A *Coleccion de documentos inéditos para la historia de Espagna*, by Pidal and others, was published in 65 vols. (Madrid 1842–1876). In 1851 the Royal Academy of History of Madrid began the publication of its *Memorial histórica español*, a collection of documents, &c. See also Dionisio Hidalgo, *Diccionario general de bibliografia española*, 7 vols. (Madrid, 1862–1881).

(2) *Works*: The standard general history of Spain written by a Spaniard is that of Don Modesto Lafuente in 30 volumes (1850–1867; new ed., by Valera, 22 vols., Barcelona, 1888). It was written before the medieval period had been properly investigated, is wordy, and largely spoilt by displays of national vanity. A later and more critical writer of nearly the same name, Don Vicente de la Fuente, has published valuable *Estudios criticos sobre la historia y el derecho de Aragon* (1884–1886). No satisfactory general history of Spain has been written by a foreigner. The best is that of M. Romey, *Histoire d'Espagne* (1843). Don Rafael Altamira has published an *Historia de España y de la civilización española* (2 vols., Barcelona, 1900–1902), in which he sums up the results of later research. Among older writers Juan de Mariana, who ends with the Catholic sovereigns, professedly took Livy as a model, and wrote a fine example of a rhetorical history published in Latin (1592–1609), and then in Spanish translated and largely re-written by himself. It was continued to 1600 by Minana. An English translation, with supplements, was published by Captain J. Stephens in 1699. *The Anales de Aragon* of Gerónimo Zurita (1610) are very far superior to the history of Mariana in criticism and research. The great school of Spanish historians died out with the other glories of the nation in the 17th century. The later periods have been indifferently treated by them, but Don Antonio Cánovas del Castillo published some valuable studies on the later Austrian dynasty under the title *Estudios del reinado de Felipe IV.* (1889). The reader may also consult—for the earlier period—Florian de Ocampo and Ambrosio de Morales, whose combined works are known as the *Crónica general de España* (fol. editions, 1543–1586, republished in 10 small volumes at Madrid, 1791–1792). This was continued by Prudencio de Sandoval, bishop of Tuy and afterwards of Pampeluna, under the title of *Hist. de los reyes de Castilla y de Leon: Fernando I.–Alonso VII.* Both ancient and later times are dealt with in the *Historia general de España, escrita por individuos de la real academia de la historia* (Madrid, 1892 sqq.)—a series of studies by different hands; that on the reign of Charles III., by Señor Manuel Danvila, is very valuable for the later 18th century. An account of the troubled years of the 19th century has been written by Don Antonia Pirala, *Historia contemporánea* (1871–1879). The latest general history of Spain is Don Rafael Altamira y Crevea's *Historia de España y de la civilización española*, 3 vols(Barcelona 1902–1906). The standard authority for the Mahommedan side of Spanish history is the *Histoire des Musulmans d'Espagne, 711–1110*, by R. P. A. Dozy (4 vols., Leiden, 1861). It requires to be supplemented by Don Pascual de Gayongos's translation of Al Makkari's *History of the Mahommedan Dynasties in Spain* (1840–1843) and by Señor Francisco Codera's *Decadencia y desaparición de los Almoravides en España* (Saragossa, 1899) and *Estudios criticos de hist. arabe española* (ibid., 1903). See also Stanley Lane Poole, *The Moors in Spain* ("Story of the Nations" Series, 1887) and S. P. Scott, *Hist. of the Moorish Empire in Europe* (3 vols., Philadelphia and London, 1904). Other English works, on general Spanish history, are Martin A. S. Hume's *Spain, its Greatness and Decay, 1479–1788* (Cambridge, 1898) and *Modern Spain, 1788–1898* ("Story of the Nations" Series, 1899), and Butler Clarke's *Modern Spain, 1815–1898* (Cambridge, 1906). Excellent summaries of Spanish history year by year are published in the *Annual Register*.

The Spanish Language

The Iberian Peninsula is not a linguistic unit. Not to speak of the Basque, which still forms an island of some importance in the north-west, three Romance languages share this extensive territory: (1) Portuguese-Galician, spoken in Portugal, Galicia, and a small portion of the province of Leon; (2) Castilian, covering about two-thirds of the Peninsula in the north, centre, and south; (3) Catalan, occupying a long strip of territory to the east and south-east.

These three varieties of the *Romana rustica* are marked off from one another more distinctly than is the case with, say the Romance dialects of Italy; they do not interpenetrate one another, but where the one ends the other begins. It has only been possible to establish at the points of junction of two linguistic regions the existence of certain mixed jargons in which certain forms of each language are intermingled; but these jargons, called into existence for the necessities of social relations by bilinguists, have an essentially individualistic and artificial character. The special development of the vulgar Latin tongue in Spain, and the formation of the three linguistic types just enumerated, were promoted by political circumstances. From the 9th century onwards Spain was slowly recaptured from the Mahommedans, and the Latin spoken by the Christians who had taken refuge on the slopes of the Pyrenees was gradually carried back to the centre and ultimately to the south of the Peninsula, whence it had been driven by the Arab invasion. Medieval Spain divides itself into three *conquistas*—that of Castile (much the most considerable), that of Portugal, and that of Aragon. If a given province now speaks Catalan rather than Castilian, the explanation is to be sought simply and solely in the fact that it was conquered by a king of Aragon and peopled by his Catalan subjects.

1. *Catalan.*—This domain now embraces, on the mainland, the Spanish provinces of Gerona. Barcelona, Tarragona and Lérida (the old principality of Catalonia), and of Castellon de la Plana, Valencia and Alicante (the old kingdom of Valencia), and, in the Mediterranean, that of the Balearic Islands (the old kingdom of Majorca). Catalan, by its most characteristic features, belongs to the Romance of southern France and not to that of Spain; it is legitimate, therefore, to regard it as imported into Spain by those *Hispani* whom the Arab conquest had driven back beyond the mountains into Languedoc, and who in the 9th century regained the country of their origin; this conclusion is confirmed by the fact that the dialect is also that of two French provinces on the north of the Pyrenees—Roussillon and Cerdagne. From the 9th to the 12th century Catalan spread farther and farther within the limits of Catalonia, properly so called; in 1229 it was brought to Majorca by Jaime el Conquistador, and in 1238 the same sovereign carried it to Valencia also. Even Murcia was peopled by Catalans in 1266, but this province really is part of the Castilian conquest, and accordingly the Castilian element took the upper hand and absorbed the dialect of the earlier colonists. The river Segura, which falls into the Mediterranean in the neighbourhood of Orihuela, a little to the north of Murcia, is as nearly as possible the southern boundary of the Catalan domain; westward the boundary coincides pretty exactly with the political frontier, the provinces of New Castile and Aragon not being at all encroached on. Catalan, which by the reunion of Aragon and the countship of Barcelona in 1137 became the official language of the Aragonese monarchy—although the kingdom of Aragon, consisting of the present provinces of Saragossa, Huesca and Teruel, has always been Castilian in speech—established a footing in Italy also, in all parts where the domination of the kings of Aragon extended, viz. in Sicily, Naples, Corsica and Sardinia, but it has not maintained itself here except in a single district of the last-named island (Alghero); everywhere else in Italy, where it was not spoken except by the conquerors, nor written except in the royal chancery, it has disappeared without leaving a trace.

In the 13th century the name given to the vulgar tongue of eastern Spain was *Catalanesch* (*Catalaniscus*) or *Catalâ* (*Catalanus*)—the idiom of the Catalans.[1] By Catalanesch or Catalâ was understood, essentially, the spoken language and the language of prose, while that of poetry, with a large admixture of Provençal forms, was early called *Lemosi*, *Limosi* or language of Limousin—Catalan grammarians, and particularly the most celebrated of them, Ramon Vidal de Besalú, having adopted *Lemosi* as the generic name of the language of the troubadours. These grammarians carefully distinguish the vulgar speech, or *pla Catalâ*, from the refined *trobar* idiom, which originally is a modified form of Provençal. Afterwards, and especially in these parts of the Catalan domain outside of Catalonia which did not acknowledge that they derived their language from that province, *Lemosi* received a more extensive signification, so as to mean the literary language in general, whether of verse or of prose. To this hour, particularly in Valencia and the Balearics, *Lemosi* is employed to designate on the one hand the old Catalan and on the other the very artificial and somewhat archaizing idiom which is current in the *jochs florals*; while the spoken dialect is called, according to the localities, *Valenciâ* (in Valencia), *Majorquí* and *Menorquí* (in Majorca and Minorca), or *Catalâ* (in Catalonia); the form *Catalanesch* is obsolete.

The principal features which connect Catalan with the Romance of France and separate it from that of Spain are the following: (1) To take first its treatment of the final vowels—Catalan, like French and Provençal, having only oxytones and paroxytones, does not admit more than one syllable after the tonic accent: thus *anima* gives *arma*, *câmera* gives *cambra*. All the proparoxytones of modern Catalan are of recent introduction and due to Castilian influence. Further, the only post-tonic Latin vowel preserved by the Catalan is, as in Gallo-Roman, *a* : *mare* gives *mar*, *gratu* (*s*) gives *grat*, but *anima* gives *arma;* and, when the word terminates in a group of consonants requiring a supporting vowel, that vowel is represented by an *e*: *arb(o)rem*, Cat. *abre* (Prov. and Fr. *arbre*, but Cast. *árbol*); *pop(u)l(us)*, Cat. *poble* (Prov. *poble*, Fr. *peuple*, but Cast. *pueblo*); sometimes, when it is inserted between the two consonants instead of being made to follow them, the supporting vowel is represented by an *o* : *escândol* (scândalum), *frévol* (frivolus), *circol* (circulus). In some cases a post-tonic vowel other than *a* is preserved in Catalan, as, for example, when that vowel forms a diphthong with the tonic (*Deu*, Deus; *Ebriu*, Hebreus); or, again, it sometimes happens, when the tonic is followed by an *i* in hiatus, that the *i* persists (*dilúvi*, dilúvium; *servici*, servicium; *lâbi*, lâbium; *ciri*, cereus); but in many cases these ought to be regarded as learned forms, as is shown by the existence of parallel ones, such as *servey*, where the atonic *i* has been attracted by the tonic and forms a diphthong with it (*servíci*, *servii*, *servey*). What has just been said as to the treatment of the final vowels in Catalan must be understood as applying only to pure Catalan, unaltered by the predominance of the Castilian, for the actual language is no longer faithful to the principle we have laid down; it allows the final *o* atonic in a number of substantives and adjectives, and in the verb it now conjugates *canto*, *temo*, *sento*—a thing unknown in the ancient language. (2) As regards conjugation only two points need be noted here: (*a*) it employs the form known as the inchoative, that is to say, the lengthening of the radical of the present in verbs of the third conjugation by means of the syllable *ex* or *ix*, a proceeding common to Italian, Walachian, Provençal and French, but altogether unknown in Hispanic Romance; (*b*) the formation of a great number of past participles in which the termination is added, as in Provençal, not to the radical of the verb, but to that of the perfect: *tingut* from *tinch*, *pogut* from *poch*, *conegut* from *conech*, while in Castilian *tenido* (formerly also *tenudo*), *podido*, *conocido*, are participles formed from the infinitive.

As for features common to Catalan and Hispanic (Castilian and Portuguese) Romance, on the other hand, and which are unknown to French Romance, only one is of importance; the conservation, namely, of the Latin *u* with its original sound, while the same vowel has assumed in French and Provençal,

[1] The origin of the name *Catalanus* is unknown.

from a very early period—earlier doubtless than the oldest existing monuments of those languages—a labio-palatal pronunciation (*ü*). It is not to be supposed that the separation of Catalan from the Gallo-Roman family occurred before the transformation had taken place; there is good reason to believe that Catalan possessed the *ü* at one time, but afterwards lost it in its contact with the Spanish dialects.

Catalan being a variety of the *langue d'oc*, it will be convenient to note the peculiarities of its phonetics and inflexion as compared with ordinary Provençal.

Tonic Vowels.—With regard to *a*, which is pronounced alike in open and close syllables (*amar*, a m a r e; *abre*, a r b o r), there is nothing to remark. The Latin *ē*, which is treated like *ĭ*, gives *e*, sometimes close, sometimes open. On this point Catalan is more hesitating than Provençal; it does not distinguish so clearly the pronunciation of *e* according to its origin; while *ē* (*ĭ*) is capable of yielding an open *e*, the *ĕ* is often pronounced close, and the poets have no difficulty in making words in *e* close and in *e* open rhyme together, which is not the case in Provençal. The Latin *ĕ* never yields *ie* in Catalan as it does in French and occasionally in Provençal; s e d e t becomes *seu* (where *u* represents the final *d*), p e d e m makes *peu*, and e g o *eu*; in some words where the tonic *ĕ* is followed by a syllable in which an *i* occurs, it may become *i* (*ir*, h ĕ r i; *mig*, m ĕ d i u s; *mils*, m ē l i u s); and the same holds good for *ē* in a similar situation (*ciri*, c ē r i u s, c ē r e u s; *fira*, f ē r i a), and for *e* in a close syllable before a nasal (*eximpli*, e x e m p l u m; *mintré* for *mentiré*, *gint* for *gent*). *I* tonic long and *ĭ* short, when in hiatus with another vowel, produce *i* (*amich*, a m i c u s; *via*, v ĭ a). *O* tonic long and *o* short are represented by *o* close and *o* open (*amor*, a m o r e m; *poble*, p o p u l u s). *O* short is never diphthongized into *uo* or *ue*; such a treatment is as foreign to Catalan as the diphthongization of *ĕ* into *ie*. Just as *e* before a syllable in which an *i* occurs is changed into *i*, so in the same circumstances *o* becomes *u* (*full*, f o l i u m; *vull*, v o l i o for v o l e o) and also when the accented vowel precedes a group of consonants like *cl*, *pl*, and the like (*ull*, o c ' l u s; *escull*, s c o p ' l u s). Latin *u* persists with the Latin pronunciation, and, as already said, does not take the Franco-Provençal pronunciation *ü*. Latin *au* becomes *o* (*cosa*, c a u s a; *or*, a u r u m); Old Catalan has kept the diphthong better, but possibly we should attribute the examples of *au* which are met with in texts of the 13th and 14th centuries to the literary influence of Provence. Latin *ua* tends to become *o* (*cor*, q u a r e).

Atonic Vowels.—As for the Latin post-tonic vowels already spoken of, it remains to be noted that *a* is often represented in writing by *e*, especially before *s*; in old Catalan, the substantives, adjectives and participles readily form their singular in *a* and their plural in *es*: *arma*, *armes* (a n i m a, a n i m a s); *bona*, *bones* (b o n a, b o n a s); *amada*, *amades* (a m a t a, a m a t a s). This *e* is neither open nor close, but a surd *e* the pronunciation of which comes very near *a*. In the same way the supporting vowel, which is regularly an *e* in Catalan, is often written *a*, especially after *r* (*abra*, a r b o r e m; *astra*, a s t r u m; *para*, p a t r e m); one may say that in the actual state of the language post-tonic *e* and *a* become indistinguishable in a surd sound intermediate between the French *a* and mute *e*. Before the tonic the same change between *a* and *e* constantly takes place; one finds in manuscripts *enar*, *emor* for *anar*, *amor* (the same extends even to the case of the tonic syllable, *ten* and *sent* from t a n t u m and s a n c t u m being far from rare), and, on the other hand, *antre*, *arrar*, for *entre*, *errar*. *I* atonic is often represented by *e* even when it is long (*vehi*, v i c i n u s). *O* atonic close, which in genuine Catalan exists only before the tonic, has become *u*; at the present day *truvar*, *cuntradir* is the real pronunciation of the words spelt *trovar*, *contradir*, and in the final syllables, verbal or other, where under Castilian influence an *o* has come to be added to the normal Catalan form, this *o* has the value of a *u*: *trovo* (genuine Catalan, *trop*) is pronounced *trovu*; *bravo* (genuine Catalan, *brau*) is pronounced *bravu*. *U* atonic keeps its ground.

The only strong diphthongs of the spoken language are *ái*, *áu* (rather rare), *éi*, *éu*, *íu*, *ói*, *óu*, *úi*, *uu*. *Ai* produced by *a*+*i* or by *a*+a palatal consonant has for the greater part of the time become an *e* in the modern language; *factum* has yielded *fait*, *feit*, and then *fet*, the last being the actual form; *arius* has given *er* alongside of *aire*, *ari*, which are learned or semi-learned forms. Of the two weak diphthongs *ió* and *uá*, the latter, as has been seen, tends to become *o* close in the atonic syllable, and is pronounced *u*: *quaranta* has become *coranta*, then *curanta*. After the tonic *ua* often becomes *a* in the Catalan of the mainland (*ayga*, a q u a, *llenga*, l i n g u a), while in Majorca it becomes *o* (*aygo*, *llengo*).

Consonants.—Final *t* readily disappears after *n* or *l* (*tan*, t a n t u m; *aman*, *venin*, *partin*, for *amant*, *venint*, &c.; *mol*, m u l t u m; *ocul*, o c u l t u m); the *t* reappears in composition before a vowel (*fon*, f o n t e m, but *Font-alba*). On the other hand, a *t* without etymological origin is frequently added to words ending in *r* (*cart* for *car*, *quare*; *mart* for *mar*, *mare*; *amart*, *ohirt*, infinitive for *amar*, *ohir*), and even to some words terminating in a vowel (*genit*, i n g e n i u m; *premit*, p r e m i u m), or the addition of the *t* has taken place by assimilation to past participles in *it*. The phenomenon occurs also in Provençal (see *Romania*, vii. 107, viii. 110). Median intervocal *d*, represented by *s* (*z*) in the first stage of the language, has disappeared: f i d e l i s gave *fesel*, then *feel*, and finally *fel*; v i d e t i s became *vezets*, then *veets*, *vets* and *veu*. Final *d* after a vowel has produced *u* (*peu*, p e d e m; *niu*, n i d u m; *mou*, m o d u m); but when the *d*, in consequence of the disappearance of the preceding vowel, rests upon a consonant, it remains and passes into the corresponding surd; f r i g i d u s gives *fred* (pronounced *fret*). The group *dr*, when produced by the disappearance of the intermediate vowel, becomes *ur* (*creure*, c r e d e r e; *ociure*, o c c i d e r e; *veure*, v i d ĕ r e; *seure*, s e d ĕ r e). Final *n*, if originally it stood between two vowels, drops away (*bo*, b o n u m; *vi*, v i n u m), but not when it answers to *mn* (thus d o n u m makes *do*, but d o m n u m *don*; s o n u m makes *so*, but s o m n u m *son*). *Nd* is reduced to *n* (*demanar*, *comanar* for *demandar*, *comandar*). Assibilated *c* before *e*, *i* is treated like *d*: within a word it disappears after having been represented for a while by *s* (l u c e r e gives *llusir*, *lluhir*; r e c i p e r e gives *rezebre*, *reebre*, *rebre*); at the end of a word it is replaced by *u* (*veu*, v i c e m; *feu*, f e c i t). The group *c'r* gives *ur*, just like *d'r* (*jaure*, j a c ĕ r e; *naure*, n o c ĕ r e; *plaure*, p l a c ĕ r e; but f a c e r e, d i c e r e, d u c e r e, make *far* (*fer*), *dir*, *dur*. Initial *l* has been preserved only in certain monosyllables (the article *lo*, *los*); everywhere else it has been replaced by *l* mouillée (Prov. *lh*), which in the present orthography is written *ll* as in Castilian, but formerly used to be represented by *ly* or *yl* (*lletra*, l i t e r a *llengua*, l i n g u a). *P* readily disappears after *m*, like *t* after *n* (*cam*, c a m p u m; *tems*, t e m p u s). *B* is replaced by the surd *p* at the end of a word (*trobar* in the infinitive, but *trop* in the present tense); so also in the interior of a word when it precedes a consonant (*supventr*, s u b v e n i r e, *sopte*, s u b ' t o). Median intervocalic *f* gives *v* (*Estéve*, S t e p h a n u s); it has disappeared from p r o f u n d u s, which yielded the form *preon*, then *pregon* (*g* being introduced to obviate the hiatus). *V*, wherever it has been preserved, has the same pronunciation as *b*; at the end of a word and between vowels it becomes vocalized into *u* (*suau*, s u a v i s; *viure*, v i v e r e). *C* guttural, written *qu* before *e* and *i*, keeps its ground as a central and as a final letter; in the latter position it is generally written *ch* (*amich*, a m i c u m; *joch*, j o c u m). *G* guttural is replaced as a final letter by surd *c* (*longa*, but *lonc*; *trigar*, but *trich*). *Tj* after a consonant gives *ss* (*cassar*, c a p t i a r e); between vowels, after having been represented by soft *s*, it has disappeared (r a t i o n e m gave *razó*, *raysó*, then *rahó*); at the end of every word it behaves like *ts*, that is to say, changes into *u* (*preu*, p r e t i u m); instead of *ts* the second person plural of the verb—a t(i)s, e t(i)s, it(i)s—now has *au*, *eu*, *iu* after having had *ats*, *ets* *its*. *Dj* gives *ĝ* between vowels (*verger*, v i r i d i a r u m), and *c* as a terminal (written either *ig* or *tx*: *goig*, g a u d i u m *mig*, *mitx*, m e d i u m). *Stj* and *sc* before *e* and *i*, as well as *x* and *ps*, yield the sound *sh*, represented in Catalan by *x* (*angoxa*, a n g u s t i a; *coneixer*, c o g n o s c e r e; *dix*, d i x i t; *mateix*, m e t i p s e). *J* almost everywhere has taken the sound of the French *j* (*jutge*, &c.). *Lj* and *ll* give *l* mouillée (*ll* in the present orthography: *fill*, f i l i u m; *consell*, c o n s i l i u m; *null*, n u l l u m). In the larger portion of the Catalan domain this *l* mouillée has become *y* almost everywhere *fiy* is pronounced for *fill*, *consey* for *consell*. *Nj* and *nn* give *n* mouillée (*ny* in both old and modern spelling: *senyor*, s e n i o r e m; *any*, a n n u m). Sometimes the *ny* becomes reduced to *y*; one occasionally meets in manuscripts with *seyor*, *ay*, for *senyor*, *any*, but this pronunciation has not become general, as has been the case with the *y* having its origin in *ll*. Lingual *r* at the end of a word has a tendency to disappear when preceded by a vowel: thus the infinitives a m a r e, t e m e r e, *l e g i r e are pronounced *amá*, *temé*, *llegí*. It is never preserved except when protected by the non-etymological *t* already spoken of (*llegirt* or *llegí*, but never *llegír*); the *r* reappears, nevertheless, whenever the infinitive is followed by a pronoun (*donarme*, *dirho*). *Rs* is reduced to *s* (*cos* for *cors*, c o r p u s). *H* is merely an orthographic sign; it is used to indicate that two consecutive vowels do not form a diphthong (*vehi raho*), and, added to *c*, it denotes the pronunciation of the guttural *c* at the end of a word (*amich*).

Inflexion.—Catalan, unlike Old Provençal and Old French, has never had declensions. It is true that in certain texts (especially metrical texts) certain traces of case-endings are to be met with, as for example *Deus* and *Deu*, *amors* and *amor*, *clars* and *clar*, *forts* and *fort*, *tuyt* and *tots*, *abduy* and *abdos*, *senyer* and *senyor*, *emperaire* and *emperador*; but, since these forms are used convertibly, the nominative form when the word is in the objective, and the accusative form when the word is the subject, we can only recognize in these cases a confused recollection of the Provençal rules known only to the literate but of which the transcribers of manuscripts took no account. Catalan, then, makes no distinctions save in the gender and the number of its nouns. As regards the formation of the plural only two observations are necessary. (1) Words which have their radical termination in *n* but which in the singular drop that *n*, resume it in the plural before *s*: *homin-em* makes *ome* in the singular and *omens* in the plural; *asin-um* makes *ase* and *asens*. (2) Words terminating in *s* surd or sonant and in *x* anciently formed their plural by adding to the singular the syllable *es* (*bras*, *brasses*; *pres*, *preses*; *mateix*, *mateixes*), but subsequently, from about the 15th century, the Castilian influence substituted *os*, so that one now hears *brassos, presos, mateixos*. The words in *tx, sc, st* have been assimilated to words in *s* (*x*); from *bosch* we originally had the plural *bosches*, but now *boscos*; from *trist, tristes*, but now *tristos*. For these last in *st* there exists a plural formation which is more in accordance with the genius of the language, and consists in the suppression of the *s* before the *t*; from *aquest*, for example, we have now side by side the two plurals *aquestos*, in the Castilian manner, and *aquets*. The article is *lo, los* (pronounced *lu, lus* in a portion of the domain), fem. *la, les* (*las*). Some instances of *li* occur in the ancient tongue, applying indifferently to the nominative and the objective case; *el* applying to the singular is also not wholly unknown. On the north-western border of Catalonia, and in the island of Majorca, the article is not a derivative from *ille* but from *ipse* (sing. masc. *es* or *so*, fem. *sa*; pl. masc. *es*, and also *ets*, which appears to come from *istos*—*ets* for *ests*, like *aquets* for *aquests*—fem. *sas*). Compare the corresponding Sardinian forms *su, sa*, pl. *sos, sas*. On the pronouns it has only to be remarked that the modern language has borrowed from Castilian the composite forms *nosaltres* and *vosaltres* (pronounced also *nosaltros* and *nosatrus*), as also the form *vosté, vusté* (Castilian *usted* for *vuestra merced*).

Conjugation.—Catalan, and especially modern Catalan, has greatly narrowed the domain of the 2nd conjugation in ē r e; a large number of verbs of this conjugation have been treated as if they belonged to the 3rd in ĕ r e; d e b e r e makes *deure*, v i d e r e, *veure*, and alongside of *haber*, which answers to h a b ē r e, there is a form *heure* which points to h a b ĕ r e. A curious fact, and one which has arisen since the 15th century, is the addition of a paragogic *r* to those infinitives which are accented on the radical; in a portion of the Catalan domain one hears *creurer, veurer*. Some verbs originally belonging to the conjugation in ē r e have passed over into that in *ir*; for example t e n ē r e gives *tenir* alongside of *tindre*, r e m a n ē r e *romanir* and *romandre*. In the gerundive and in the present participle Catalan differs from Provençal in still distinguishing the conjugation in *ir* from that in *er, re*—saying, for example, *sentint*. As in Provençal, the past participle of a large number of verbs of the 2nd and 3rd conjugations is formed, not from the infinitive, but from the perfect (*pogut, volgut, tingut* suggest the perfects *poch, volch, tinch*, and not the infinitives *poder, voler, tenir*). In the present indicative and subjunctive many verbs in *ir* take the inchoative form already described, by lengthening the radical in the three persons of the singular and in the third person of the plural by means of the syllable *esc* (*isc*). *agrahir* has the present indicative *agraesch, agraheixes, agraheix, agraheixen*, the present subjunctive *agraesca, -as, -a, -an* (or more usually now *agraesqui, -is, -i, -in*). The old perfect of the conjugation in *ar* had *é* (also *i*) in the 1st pers. sing. and *-á* in the 3rd; alongside of the *-á*, which is proper to Catalan exclusively, we also find, in the first period of the language, *-et* as in Provençal. Subsequently the perfect of the three conjugations has admitted forms in *-r* (*amáres, amárem, amáreu, amáren*), derived from the ancient pluperfect *amara*, &c., which has held its ground down to the present day, with the meaning of a conditional in some verbs (one still hears *fora, haguera*). But the simple perfect is no longer employed in the spoken language, which has substituted for it a periphrastic perfect, composed of the infinitive of the verb and the present of the auxiliary *anar*: *vaig pendre*, for example, does not mean "I am going to take," but "I have taken." The earliest example of this periphrastic perfect carries us back to the 15th century. The most usual form of the subj. pres. in spoken Catalan is that in *-i* for all the three conjugations (*ami, -is, -i, -em, -eu -in*; *temi, -is*, &c.; *senti, -is*, &c.); it appears to be an abbreviation from *-ia*, and in effect certain subjunctives, such as *cántia, témia, tínguia, vinguia* (for *cante, tema, tinga, vingia*), evidently formed upon *sia* (subj. of *esser*), have been and still are used. The same *i* of the present subjunctive, whatever may be its origin, is still found in the imperfect: *amés, -essis, -es, -essium*, &c.

Catalan Dialect of Alghero (*Sardinia*).—As compared with that of the mainland, the Catalan of Alghero, introduced into this portion of Sardinia by the Aragonese conquerors and colonists, does not present any very important differences; some of them, such as they are, are explicable by the influence of the indigenous dialects of Sassari and Logudoro. In phonetics one observes—(1) the change of *lj* into *y* as an initial before *i* (*yitx, yigis*; *lego, legis*), a change which does not take place in the Catalan of the mainland except in the interior, or at the end of the word; (2) the frequent change of *l* between vowels and of *l* after *c, g, f, p* or *b* into *r* (*taura tabula*; *candera, candela*; *sangrot, singultum*; *frama, flama*). In conjugation there are some notable peculiarities. The 1st pers. sing. does not take the *o* which continental Catalan has borrowed from Castilian (*cant*, not *canto*, &c.); the imp. ind. of verbs of the 2nd and 3rd conjugations has *eva, iva* instead of *ia*, a form which also occurs in the conditional (*cantariva, drumiriva*); the simple perfect, of which some types are still preserved in the actual language (*e.g. anighé, aghé*), has likewise served for the formation not only of the past participle but also of the infinitive (*agher, habere*, can only be explained by *ach*, 3rd person of the perfect); the infinitives with *r* paragogic (*viurer, seurer, plourer*) are not used (*viure, seure, ploure* instead); in the conjugation of the present of the verb *essar* or *esser*, the 2nd pers. sing. *ses* formed upon the persons of the plural, while continental Catalan says *ets* (anciently *est*), as also, in the plural, *sem, seu*, instead of *som, sou*, are to be noted; *tenere* has passed over to the conjugation in *re* (*trenda* = *tendre*), but it is at the same time true that in ordinary Catalan also we have *tindrer* alongside of *tenir* the habitual form; *dicere* gives not *dir* but *diure*, which is more regular.

2. *Castilian.*—This name is the most convenient designation to apply to the linguistic domain which comprises the whole of central Spain and the vast regions of America and Asia colonized from the 16th century onwards by the Spaniards. We might also indeed call it the *Spanish* domain, narrowing the essentially geographical meaning of the word *Español* (derived, like the other old form *Españon*, from *Hispania*), and using it in a purely political sense. But the first expression is to be preferred, all the more because it has been long in use, and even the inhabitants of the domain outside the two Castiles fully accept it and are indeed the first to call their idiom *Castellano*. It is agreed on all hands that Castilian is one of the two branches of the vulgar Latin of Spain, Portuguese-Galician being the other; both idioms, now separated by very marked differences, can be traced back directly to one common source—the Hispanic Romance. One and the same vulgar tongue, diversely modified in the lapse of time, has produced Castilian and Portuguese as two varieties, while Catalan, the third language of the Peninsula, connects itself, as has already been pointed out, with the Gallo-Roman.

Within the Castilian domain, thus embracing all in Spain that is neither Portuguese nor Catalan, there exist linguistic varieties which it would perhaps be an exaggeration to call dialects, considering the meaning ordinarily attached to that word, but which are none the less worthy of attention. Generally speaking, from various circumstances, and especially that of the reconquest, by which the already-formed idiom of the Christian conquerors and colonists was gradually conveyed from north to south, Castilian has maintained a uniformity of which the Romance languages afford no other example. We shall proceed in the first instance to examine the most salient features of the *normal Castilian*, spoken in the provinces more or less closely corresponding to the old limits of Old and New Castile, so as to be able afterwards to note the peculiarities of what, for want of a better expression, we must call the Castilian dialects.

In some respects Castilian is hardly further removed from classical Latin than is Italian; in others it has approximately reached the same stage as Provençal. As regards the tonic, accent and the treatment of the vowels which come after it, Castilian may be said to be essentially a paroxytonic language, though it does not altogether refuse proparoxytonic accentuation and it would be a mistake to regard vocables like *lámpara, lágrima, rápido*, &c., as learned words. In this feature, and in its almost universal conservation of the final vowels *e, i, u* (*o*), Castilian comes very near Italian, while it separates from it and approaches the Gallo-Roman by its modification of the consonants.

Vowels.—Normal Castilian faithfully preserves the vowels ē, ī, ō, ū; the comparatively infrequent instances in which ē and ō are treated like ĕ and ŏ must be attributed to the working of analogy. It diphthongizes ĕ in *ie*, ŏ in *ue*, which may be regarded as a weakening of *uo* (see *Romania*, iv. 30). Sometimes *ie* and *ue* in the modern language are changed into *i* and *e*: *silla* from s ĕ l l a (Old Cast. *siella*), *víspera* from v ĕ s p e r a (Old Cast. *viespera*), *castillo* from c a s t ĕ l l u m (Old Cast. *castiello*), *frente* from f r o n t e m (Old Cast. *fruente*), *fleco* from f l ŏ c c u s (Old Cast. *flueco*). The words in which ĕ and ŏ have kept their ground are either learned words like *médico, mérito*, or have been borrowed from dialects which do not suffer diphthongization. In many cases the old language is more rigorous; thus, while modern Castilian has given the preference to *mente, como, modo*, we find in old texts *miente, cuemo, muedo*. Lat. a u makes *o* in all words of popular origin (*cosa, oro*, &c.).

Consonants.—On the liquids *l, m, n, r* there is little to be remarked, except that the last-named letter has two pronunciations—one soft (voiced), as in *amor, burla*, the other hard (voiceless), as in *rendir, tierra* (Old Cast. in this case goes so far as to double the initial consonant: *rrendir*)—and that *n* is often inserted before *s* and *d*: *ensayo, mensage, rendir* (r e d d e r e). *L* mouillée (written *ll*) represents not only the Latin *l, ll, lj*, but also, at the beginning of words, the combinations *cl, gl, pl, bl, fl*: *llama* (f l a m m a), *llave* (clavis), *llorar* (plorare); the tendency of the modern language is, as in Catalan, to reduce *ll* to *y*; thus one readily hears *yeno* (plenum). *N* mouillée (*ñ*) corresponds to the Lat. *nn, mn, nj*, and sometimes to initial *n*: *año* (annum), *daño* (damnum), *ñudo* (nodum). Passing to the dentals, except as an initial, *t* in words that are popularly current and belong to the old stock of the language, can only be derived from Lat. *tt, pt*, and sometimes *ct*, as in *meter* (mittere), *catar* (captare), *punto* (punctum); but it is to be observed that the habitual mode of representing *ct* in normal Castilian is by *ch* (pron. *tch*), as in *derecho* (directum), *pecho* (pectus), so that we may take those words in which *t* alone represents *ct* as secondary forms of learned words; thus we have *bendito, otubre, santo* as secondary forms of the learned words *bendicto, octubre, sancto*, alongside of the old popular forms *bendicho, ochubre, sancho*. *D* corresponds in Castilian to Latin *t* between vowels, or *t* before *r*: *amado* (amatus), *padre* (patrem). At the present day the *d* of the suffixes *ado, ido* is no longer pronounced throughout the whole extent of the domain, and the same holds good also of the final *d*: *salú, poné*, for *salud, poned* (from salutem, ponite). Sometimes *d* takes the interdental sound of *z* (English *th*), or is changed into *l*; witness the two pronunciations of the name of the capital—*Madriz* and *Madril* (adj. *Madrileño*). The study of the spirants, *c, z, s; g, j* is made a very delicate one by the circumstance that the interdental pronunciation of *c, z* on the one hand, and the guttural pronunciation of *g, j* on the other, are of comparatively recent date, and convey no notion of the value of these letters before the 17th century. It is admitted, not without reason, that the spirants *c, z*, which at present represent but one interdental sound (a lisped *s*, or a sound between *s* and Eng. *th* in thing), had down till about the middle of the 16th century the voiceless sound *ts* and the voiced sound *dz* respectively, and that in like manner the palatal spirants *g, j, x*, before assuming the uniform pronunciation of the guttural spirant (=Germ. *ch* in *Buch*), had previously represented the voiced sound of *ž* (Fr. *j*) and the voiceless sound of *š* (Fr. *ch*), which are still found in Portuguese and in the Castilian dialects of the north-west. The substitution of these interdental and guttural sounds for the surd and sonant spirants respectively did certainly not take place simultaneously, but the vacillations of the old orthography, and afterwards the decision of the Spanish Academy, which suppressed *x* (=*š*; *x* was retained for *cs*) and allows only *c* and *g* before *e* and *i*, *z* and *j* before *a, o, u*, make it impossible for us to follow, with the help of the written texts, the course of the transformation. *S* now has the voiceless sound even between vowels: *casa* (pronounced *cassa*); final *s* readily falls away, especially before liquids: *todo los* for *todos los*, *vamono* for *vamos nos*. The principal sources of *j* (*g*) are—Lat. *j* and *g* before *e* and *i* (*juego*, jocum; *gente*, gentem); Lat. initial *s* (*jabon*, saponem); Lat. *x* (*cojo*, coxum); *lj, cl* (*consejo*, consilium; *ojo*, oc'lum). The sources of *z* (*c*) are Lat. *ce, cj, tj, s* (*cielo*, caelum; *calza*, calcea; *razon*, rationem; *zampoña*, symphonia). As regards the spirants *f* and *v*, it is to be observed that at the beginning of a word *f* has in many instances been replaced by the aspirated *h* (afterwards silent), while in others no less current among the people the transformation has not taken place; thus we have *hijo* (filium) alongside of *fiesta* (festa). In some cases the *f* has been preserved in order to avoid confusion that might arise from identity of sound: the *f* in *fiel* (fidelis) has been kept for the sake of distinction from *hiel* (fel). As for *v*, it has a marked tendency to become confounded, especially as an initial letter, with the sonant explosive *b*; Joseph Scaliger's pun—*bibere est vivere*—is applicable to the Castilians as well as to the Gascons. *H* is now nothing more than a graphic sign, except in Andalusia, where the aspirate sound represented by it comes very near *j*. Words beginning in *hue*, where the *h*, not etymologically derived, marks the inseparable aspiration of the initial diphthong *ue*, are readily pronounced *güe* throughout almost the whole extent of the domain: *güele* for *huele* (olet); *güeso* for *hueso* (os). This *güe* extends also to words beginning with *bue*: *güeno* for *bueno* (bonum).

Inflexion.—There is no trace of declension either in Castilian or in Portuguese. Some nominative forms—*Diós* (anciently *Díos*, and in the Castilian of the Jews *Dío*), *Cárlos, Márcos, sastre* (sártor)—have been adopted instead of forms derived from the accusative, but the vulgar Latin of the Peninsula in no instance presents two forms (subjective and objective case) of the same substantive. The article is derived from ille, as it is almost everywhere throughout the Romance regions: *el, la*, and a neuter *lo*; *los, las*. The plural of the first and second personal pronoun has in the modern language taken a composite form—*nosotros, vosotros*—which has been imitated in Catalan. *Quien*, the interrogative pronoun which has taken the place of the old *qui*, seems to come from quem.

Conjugation.—The conjugation of Castilian (and Portuguese) derives a peculiar interest from the archaic features which it retains. The vulgar Latin of Spain has kept the pluperfect indicative, still in current use as a secondary form of the conditional (*cantára, vendiéra, partiéra*), and, what is more remarkable still, as not occurring anywhere else, the future perfect (*cantáre, vendiére, partiére*, formerly *cantáro, vendiéro, partiéro*). The Latin future has been replaced, as everywhere, by the perirphasis (cantare habeo), but it is worth noticing that in certain old texts of the 13th century, and in the popular songs of a comparatively ancient date which have been preserved in Asturias, the auxiliary can still *précede* the infinitive (habeo cantare), as with the Latin writers of the decadence: "Mucho de mayor preçio a seer el tu manto Que non será el nuestro" (Berceo, *S. Laur.*, str. 70), where *a seer* (habet sedere) corresponds exactly to *será* (sedere habet). The vulgar Latin of the Peninsula, moreover, has preserved the 2nd pers. pl. of the imperative (*cantad, vended, partid*), which has disappeared from all the other Romance languages. Another special feature of Castilian-Portuguese is the complete absence of the form of conjugation known as inchoative (intercalation, in the present tense, of the syllable *isc* or *esc* between the radical and the inflexion), although in all the other tenses, except the present, Spanish shows a tendency to lay the accent upon the same syllable in all the six persons, which was the object aimed at by the inchoative form. Castilian displaces the accent on the 1st and 2nd pers. pl. of the imperfect (*cantábamos, cantábais*), of the pluperfect indicative (*cantáramos, cantárais*), and of the imperfect subjunctive (*cantásemos, cantáseis*); possibly the impulse to this was given by the forms of future perfect *cantáremos, cantáreis* (*cantarīmus, cantarītis*). The 2nd persons plural were formerly (except in the perfect) *-ades, -edes, -ides*; it was only in the course of the 16th century that they got reduced, by the falling away of *d*, to *ais, eis* and *is*. The verb essere has been mixed, not as in the other Romance languages with stare, but with sedere, as is proved by older forms *seer, siedes, sieden, seyendo*, obviously derived from sedere, and which have in the texts sometimes the meaning of "to be seated," sometimes that of "to be," and sometimes both. In old Latin charters also sedere is frequently met with in the sense of esse: *e.g.* "*sedeat* istum meum donativum quietum et securum" (anno 1134), where *sedeat*=*sit*. The 2nd pers. sing. of the present of *ser* is *eres*, which is best explained as borrowed from the imperfect (*eras*), this tense being often used in Old Spanish with the meaning of the present; alongside of *eres* one finds (but only in old documents or in dialects) *sos*, formed like *sois* (2nd pers. pl.) upon *somos*. The accentuation in the inflexion of perfects in the conjugation called strong, like *hubiéron hiziéron*, which correspond to habuērunt, fecērunt (while in the other Romance languages the Latin type is ĕrunt: Fr. *eurent, firent*), may be regarded as truly etymological, or rather as a result of the assimilation of these perfects to the perfects known as weak (*amáron*), for there are dialectic forms having the accent on the radical, such as *dixon, hizon*. The past participle of verbs in *er* was formerly *udo* (utus) in most cases; at present *ido* serves for all verbs in *er* and *ir*, except some ten or twelve in which the participle has retained the Latin form accented on the radical: *dicho, hecho, visto*, &c. It ought to be added that the past participle in normal Castilian derives its theme not from the perfect, but from the infinitive: *habido, sabido*, from *haber, saber*, not from *hubo, supo*.

Castilian Dialects.—To discover the features by which these are distinguished from normal Castilian we must turn to old charters and to certain modern compositions in which the provincial forms of speech have been reproduced more or less faithfully.

Asturian.—The Asturian idiom, called by the natives *bable*, is differentiated from the Castilian by the following characters. *Ie* occurs, as in Old Castilian, in words formed with the suffix *ellum* (*castiellu, portiellu*), while modern Castilian has reduced *ie* to *i*. *E, i, u*, post-tonic for *a, e, o*: *penes* (*penas*), *gracies* (*gracias*), *esti* (*este*), *frenti* (*frente*), *llechi* (*leche*), *nuechi* (*noche*), *unu* (*uno*), *primeru* (*primero*). There is no guttural spirant, *j*, but, according to circumstances, *y* or *x* (*š*); thus Lat. *cl, lj* gives *y*: *veyu* (*veclus), *espeyu* (spec'lum), *conseyu* (consilium); and after an *i* this *y* is hardly perceptible, to judge by the forms *fiu* (filium), *escoidos* (Cast. *escogidos*), *Castia* (*Castilla*); Lat. *g* before *e* and *i*, Lat. initial *j*, and Lat. *ss, x*, give *x* (*š*)—*xiente* (gentem), *xudiu* (Judaeus), *baxu* (bassus), *coxu* (coxus), *floxu* (fluxus). Lat. initial *f* has kept its ground, at least in part of the province: *fiu, fueya* (Cast. *hijo, hoja*). A very marked feature is the habitual "mouillure" of *l* and *n* as initial letters: *lleche, lleer, lluna, llutu*; *ñon, ñunca, ñueve, ñube*. With respect to inflexion the following forms may be noted: personal pronouns: *i* (*illi*), *yos* (*illos*); possessive pronouns: *mió*, pl. *miós*; *to, tos*; *so, sos* for both masc. and fem.; verbs: 3rd pers. pl. imp. of the 2nd and 3rd conjugations in *in* for *ien* (Cast. *ian*); *train, tenin, facin* (from *facer*), *fiin* (from *fer*), and even some instances of the 2nd pers. sing. (*abis*; Cast. *habias*); instances of pres. subj. in *ia* for *a* (*sírvia, métia, sépia*). The verb *ser* gives *yes* (sometimes *yeres*) in the 2nd pers. sing., *ye* in the 3rd. Facere appears under two forms—*facer* and *fer*—and to the abridged form correspond *feis, fiendo, fiin*, &c. Ire often appears under the form *dir* (*antes de diros*=*antes de iros*), which it is not necessary to explain by *de-ire* (see H. Schuchardt, *Ztschr. f. rom. Philol.*, v. 312).

Navarrese-Aragonese.—In its treatment of the post-tonic vowels this dialect parts company with normal Castilian and comes nearer Catalan, in so far as it drops the final *e*, especially after *nt, rt* (*mont, plazient, muert, fuert, parents, gents*); and, when the atonic *e* has dropped after a *v*, this *v* becomes a vowel—*breu* (brevem), *grieu* (*grevem), *nueu* (novem). Navarrese-Aragonese has the diphthongs *ie, ue* from tonic *ĕ* and *ŏ*, and adheres more strictly to them than normal Castilian does—*cuende* (cŏmitem), *huey* (hŏdie), *pueyo* (pŏdium), *yes* (ĕst), *yeran* (ĕrant), while

Castilian says *conde, hoy, poyo, es, eran*. The initial combinations *cl, pl, fl*, have withstood the transformation into *ll* better than in Castilian: *plano, pleno, plega, clamado, flama* are current in old documents; and at the present day, although the *l* has come to be "mouillée," the first consonant has not disappeared (*plluma, pllorá, pllano*—pronounced *pljuma*, &c.). Lat. *ct* gives *it*, not *ch* as in Castilian: *nueyt* (n o c t e m), *destruito* (d e s t r u c t u m), *proveito* (p r o v e c t u m), *dito* for *diito* (d i c t u m). *D* between vowels kept its ground longer than in Castilian: documents of the 14th century supply such forms as *vidieron, vido, hudio, provedir, redemir, prodeza, Benedit, vidiendo*, &c.; but afterwards *y* came to be substituted for *d* or *dj*: *veyere* (v i d e r e), *seyer* (s e d e r e), *seya* (s e d e a t), *goyo* (g a u d i u m), *enueyo* (i n o d i u m). Initial *f* does not change into *h*: *fillo, feito*. Navarrese-Aragonese does not possess the guttural spirant (*j*) of Castilian, which is here rendered according to circumstances either by *g* (Fr. *j*) or by *ll* (*l* mouillée), but never by the Asturian *x*. Certain forms of the conjugation of the verb differ from the Castilian: *dar, estar, haver, saber, poner* readily form their imperfects and imperfect subjunctives like the regular verbs in *ar* and *er*—*havieron* (Cast. *hubieron*), *estaron* (Cast. *estubieron*), *sabió* (Cast. *supo*), *dasen* (Cast. *diesen*), *poniese* (Cast. *pusiese*); on the other hand, past participles and gerundives formed from the perfect are to be met with—*fisiendo* for *faciendo* (perf. *fiso*), *tuviendo* and *tuvido* for *teniendo, tenido* (perf. *tuvo*). In the region bordering on Catalonia the simple perfect has given way before the periphrastic form proper to Catalan: *voy cayer* (I fell), *va fé* (he has done), *vamos ir* (we went), &c.; the imperfects of verbs in *er, ir*, moreover, are found in *eba, iba* (*comeba, subiba*, for *comia, subia*), and some presents also occur where the Catalan influence makes itself felt: *estigo* (Cat. *estich*), *vaigo* (Cat. *vaig*), *veigo* (Cat. *veig*). Navarrese-Aragonese makes use of the adverb *en* as a pronoun: *no les en daren pas, no'n hi ha*.

Andalusian.—The word "dialect" is still more appropriately applied to Andalusian than either to Asturian or Navarrese-Aragonese. Many peculiarities of pronunciation, however, are commonly called Andalusian which are far from being confined to Andalusia proper, but are met with in the vulgar speech of many parts of the Castilian domain, both in Europe and in America. Of these but a few occur only there, or at least have not yet been observed elsewhere than in that great province of southern Spain. They are the following: *L, n, r, d* between vowels or at the end of a word disappear: *sá* (*sal*), *só* (*sol*), *viee* (*viene*), *tiee* (*tiene*), *paa* and *pa* (*para*), *mia* (*mira*), *naa* and *na* (*nada*), *too* and *to* (*todo*). *D* is dropped even from the beginning of a word: *e* (*de*), *inero* (*dinero*), *on* (*don*). Before an explosive, *l, r, d* are often represented by *i*: *saiga* (*salga*), *vaiga* (*valga*), *laigo* (*largo*), *maire* (*madre*), *paire* (*padre*). Lat. *f* is more rigorously represented by *h* than in normal Castilian, and this *h* here preserves the aspirate sound which it has lost elsewhere; *hablá, horma* (*forma*), *hoder*, are pronounced with a very strong aspiration, almost identical with that of *j*. The Andalusians also very readily write these words *jablá, jorma, joder*. This aspirate, expressed by *j*, often has no etymological origin; for example, *Jándalo*, a nickname applied to Andalusians, is simply the word *Andaluz* pronounced with the strong aspiration characteristic of the inhabitants of the province. *C, z* are seldom pronounced like *s*; but a feature more peculiar to the Andalusians is the inverse process, the softened and interdental pronunciation of the *s* (the so-called *ceceo*): *zeñor* (*señor*), &c. Before a consonant and at the end of a word *s* becomes a simple aspiration: *mihmo* (*mismo*), *Dioh* (*Dios*), *do reales* (*dos reales*). In the inflexion of the verb there is nothing special to note, except some instances of 2nd pers. sing. of the perfect in *tes* for *te*: *estuvistes, estuvites*, for *estuviste*—evidently a formation by analogy from the 2nd pers. of the other tenses, which all have *s*.

It is with the Andalusian dialect that we can most readily associate the varieties of Castilian which are spoken in South America. Here some of the most characteristic features of the language of the extreme south of Spain are reproduced—either because the Castilian of America has spontaneously passed through the same phonetic transformations or because the Andalusian element, very strongly represented in colonization, succeeded in transporting its local habits of speech to the New World.

Leonese.—Proceeding on inadequate indications, the existence of a Leonese dialect has been imprudently admitted in some quarters; but the old kingdom of Leon cannot in any way be considered as constituting a linguistic domain with an individuality of its own. The fact that a poem of the 13th century (the *Alexandro*), and certain redactions of the oldest Spanish code, the *Fuero Juzgo*, have a Leonese origin has been made too much of, and has led to a tendency to localize excessively certain features common to the whole western zone where the transition takes place from Castilian to Galician-Portuguese.

3. Portuguese.—Portuguese-Galician constitutes the second branch of the Latin of Spain. In it we must distinguish—(1) Portuguese (*Portuguez*, perhaps a contraction from the old *Portugalez* = Portugalensis), the language of the kingdom of Portugal and its colonies in Africa, Asia and America (Brazil); (2) Galician (*Gallego*), or the language of the old kingdom of Galicia (the modern provinces of Pontevedra, La Coruña, Orense, and Lugo) and of a portion of the old kingdom of Leon (the territory of Vierzo in the province of Leon). Portuguese, like Castilian, is a literary language, which for ages has served as the vehicle of the literature of the Portuguese nation constituted in the beginning of the 12th century. Galician, on the other hand, which began a literary life early in the middle ages—for it was employed by Alfonso the Learned in his *Cantigas* in honour of the Virgin—decayed in proportion as the monarchy of Castile and Leon, to which Galicia had been annexed, gathered force and unity in its southward conquest. At the present day Gallego, which is simply Portuguese variously modified and with a development in some respects arrested, is much less important than Catalan, not only because the Spaniards who speak it (1,800,000) are fewer than the Catalans (3,500,000), but also because, its literary culture having been early abandoned in favour of Castilian, it fell into the vegetative condition of a provincial patois. Speaking generally, Portuguese is further removed than Castilian from Latin; its development has gone further, and its actual forms are more worn out than those of the sister language, and hence it has, not without reason, been compared to French, with which it has some very notable analogies. But, on the other hand, Portuguese has remained more exclusively Latin in its vocabulary, and, particularly in its conjugation, it has managed to preserve several features which give it, as compared with Castilian, a highly archaic air. Old Portuguese, and more especially the poetic language of the 13th century, received from the language of the troubadours, in whose poetry the earlier Portuguese poets found much of their inspiration, certain words and certain turns of expression which have left upon it indelible traces.

Vowels.—Lat. *ĕ, ŏ* with the accent have not been diphthongized into *ie, uo, ue*: *pé* (p e d e m), *dez* (d e c e m), *bom* (b o n u s), *pode* (p o t e t). On the other hand, Portuguese has a large number of strong diphthongs produced by the attraction of an *i* in hiatus or the resolution of an explosive into *i*: *raiba* (r a b i a), *feira* (f e r i a), *feito* (f a c t u m), *seixo* (s a x u m), *oito* (o c t o). A quite peculiar feature of the language occurs in the "nasal vowels," which are formed by the Latin accented vowels followed by *m, n*, or *nt, nd*: *bẽ* (b e n e), *grã* (g r a n d e m), *bõ* (b o n u m). These nasal vowels enter into combination with a final atonic vowel: *irmão* (g e r m a n u s); also *amão* (a m a n t), *sermão* (s e r m o n e m), where the *o* is a degenerated representative of the Latin final vowel. In Old Portuguese the nasal vowel or diphthong was not as now marked by the *til* (~), but was expressed indifferently and without regard to the etymology by *m* or *n*: *bem* (b e n e), *tan* (t a n t u m), *disserom* (d i x e r u n t), *sermom* (s e r m o n e m). The Latin diphthong *au* is rendered in Portuguese by *ou* (*ouro*, a u r u m; *pouco*, p a u c u m), also pronounced *oi*. With regard to the atonic vowels, there is a tendency to reduce *a* into a vowel resembling the Fr. *e* "muet," to pronounce *o* as *u*, and to drop *e* after a group of consonants (*dent* for *dente*).

Consonants.—Here the most remarkable feature, and that which most distinctly marks the wear and tear through which the language has passed, is the disappearance of the median consonants *l* and *n*: *corõa* (c o r o n a), *lua* (l u n a), *pôr* formerly *poer* (p o n e r e), *conego* (c a n o n i c u s), *vir* (v e n i r e), *dôr*, formerly *door* (d o l o r e m), *paço* (p a l a t i u m), *saude* (s a l u t e m), *pego* (p e l a g u s). Lat. *b* passes regularly into *v*: *cavallo* (c a b a l l u s), *fava* (f a b a), *arvore* (a r b o r e m); but, on the other hand, Lat. initial *v* readily tends to become *b*: *bexiga* (v e s i c a), *bodo* (v o t u m). Lat. initial *f* never becomes *h*: *fazer* (f a c e r e), *filo* (f i l u m). Lat. *c* before *e* and *i* is represented either by the hard sibilant *s* or by the soft *z*. Lat. *g* between vowels is dropped before *e* and *i*: *ler* for *leer* (l e g e r e), *dedo* (d i g i t u m); the same is the case with *d*, of course, in similar circumstances: *remir* (r e d i m e r e), *rir* (r i d e r e). Lat. *j* has assumed the sound of the French *j*. The Latin combinations *cl, fl, pl* at the beginning of words are transformed in two ways in words of popular origin. Either the initial consonant is retained while the *l* is changed into *r*: *cravo* (c l a v u m), *prazer* (p l a c e r e), *fror* (f l o r e m); or the group is changed in *ch* (= Fr. *ch*, Catal. *x*) through the intermediate sounds *kj, fj, pj*: *chamar* (c l a m a r e), *chao* (p l a n u s), *chamma* (f l a m m a). Within the word the same group and other groups also in which the second consonant is an *l* produce *l* mouillée (written *lh*, just as *n* mouillée is written *nh*, as in Provençal): *ovelha* (o v i c' l a), *velho* (*v e c l u s); and sometimes *ch*: *facho* (f a c' l u m), *ancho* (a m p l u m). Lat. *ss* or *sc* before *e* and *i* gives *x* (Fr. *ch*): *baixo* (b a s s u s), *faxa* (f a s c i a). The group *ct* is reduced to *it*: *leito* (l e c t u m), *peito* (p e c t u s), *noite* (n o c t e m); sometimes to *ut*: *douto* (d o c t u s). Such words as *fruto, reto, dileto* are modern derivatives from the learned forms *fructo*.

recto, dilecto. Lat. *cs* becomes *is*: *seis* (s e x); or *isc, x* (=Fr. *ich, ch*): *seixo* (s a x u m), *luxo* (l u x u m); or even *ss*: *disse* (d i x i).

Inflexion.—The Portuguese article, now reduced to the vocalic form *o, a, os, as*, was *lo* (exceptionally also *el*, which still survives in the expression *El-Rei*), *la, los, las* in the old language. Words ending in *l* in the singular lose the *l* in the plural (because it then becomes median, and so is dropped): *sol* (s o l e m), but *soes* (s o l e s); those having *ão* in the sing. form the plural either in *ães* or in *ões* according to the etymology: thus *cão* (c a n e m) makes *cães*, but *ração* makes *rações*. As regards the pronoun, mention must be made of the non-etymological forms of the personal *mim* and of the feminine possessive *minha*, where the second *n* has been brought in by the initial nasal. Portuguese conjugation has more that is interesting. In the personal suffixes the forms of the 2nd pers. pl. in *ades, edes, ides* lost the *d* in the 15th century, and have now become *ais, eis, is*, through the intermediate forms *aes, ees, eis*. The form in *des* has persisted only in those verbs where it was protected by the consonants *n* or *r* preceding it: *pondes, tendes, vindes, amardes*, and also no doubt in some forms of the present of the imperative, where the theme has been reduced to an extraordinary degree by the disappearance of a consonant and the contraction of vowels: *ides, credes, ledes*, &c. Portuguese is the only Romance language which possesses a personal or conjugated infinitive: *amar, amar-es, amar, amar-mos, amar-des, amar-em*; e.g. *antes de sair-mos*, "before we go out." Again, Portuguese alone has preserved the pluperfect in its original meaning, so that, for example, *amara* (a m a v e r a m) signifies not merely as elsewhere "I would love," but also "I had loved." The future perfect, retained as in Castilian, has lost its vowel of inflexion in the 1st and 3rd pers. sing. and consequently becomes liable to be confounded with the infinitive (*amar, render, partir*). Portuguese, though less frequently than Castilian, employs *ter* (t e n e r e) as an auxiliary, alongside of *aver*; and it also supplements the use of e s s e r e with s e d e r e, which furnished the subj. *seja*, the imperative *se, sede*, the gerundive *sendo*, the participle *sido*, and some other tenses in the old language. Among the peculiarities of Portuguese conjugation may be mentioned—(1) the assimilation of the 3rd pers. sing. to the 1st in strong perfects (*houve, pude, quiz, fez*), while Castilian has *hube* and *hubo*; (2) the imperfects *punha, tinha, vinha* (from *por, ter* and *vir*), which are accented on the radical in order to avoid the loss of the *n* (*ponía* would have made *poía*), and which substitute *u* and *i* for *o* and *e* in order to distinguish from the present subjunctive (*ponha, tenha, venha*).

Galician.—Almost all the phonetic features which distinguish Portuguese from Castilian are possessed by Gallego also. Portuguese and Galician even now are practically one language, and still more was this the case formerly: the identity of the two idioms would become still more obvious if the orthography employed by the Galicians were more strictly phonetic, and if certain transcriptions of sounds borrowed from the grammar of the official language (Castilian) did not veil the true pronunciation of the dialect. It is stated, for example, that Gallego does not possess nasal diphthongs; still it may be conceded once for all that such a word as p l a n u s, which in Galician is written sometimes *chau* and sometimes *chan*, cannot be very remote from the Portuguese nasal pronunciation *chao*. One of the most notable differences between normal Portuguese and Galician is the substitution of the surd spirant in place of the sonant spirant for the Lat. *j* before all vowels and *g* before *e* and *i*: *xuez* (j u d i c e m), Port. *juiz*; *xunto* (j u n c t u m), Port. *junto*; *xente* (g e n t e m). Port. *gente*. In conjugation the peculiarities of Gallego are more marked; some find their explanation within the dialect itself, others seem to be due to Castilian influence. The 2nd persons plural have still their old form *ades, edes, ides*, so that in this instance it would seem as if Gallego had been arrested in its progress while Portuguese had gone on progressing; but it is to be observed that with these full forms the grammarians admit contracted forms as well: *ás* (Port. *ais*), *és* (Port. *eis*), *ís* (Port. *is*). The 1st pers. sing. of the perfect of conjugations in *er* and *ir* has come to be complicated by a nasal resonance similar to that which we find in the Portuguese *mim*; we have *vendin, partin*, instead of *vendi, parti*, and by analogy this form in *in* has extended itself also to the perfect of the conjugation in *ar*, and *falin, gardin*, for *falei, gardei* are found. The second persons of the same tense take the ending *che, ches* in the singular and *chedes* in the plural: *falache* or *falaches* (f a b u l a s t i), *falachedes* as well as *falástedes* (f a b u l a s t i s), *bateche* or *batiche*, pl. *batestes* or *batechedes*, &c. *Ti* (t i b i) having given *che* in Galician, we see that *falasti* has become *falache* by a phonetic process. The 3rd pers. sing. of strong perfect is not in *e* as in Portuguese (*houve, pode*), but in *o* (*houbo, puido, soubo, coubo*, &c.); Castilian influence may be traceable here. If a contemporary grammarian, Saco Arce, is to be trusted, Gallego would form an absolute exception to the law of Spanish accentuation in the imperfect and pluperfect indicative: *falabámos, falabádes*; *batiámos, batiádes*; *pidiámos, pidiádes*; and *falarámos, folarádes*; *baterámos, baterádes*; *pidirámos, pidirádes*. The future perfect indicative and the imperfect subjunctive, on the other hand, would seem to be accented regularly: *faláremos, falásemos*. The important question is worth further study in detail.

Bibliography.—On the general subject the most important works are F. Diez, *Grammatik der romanischen Sprachen* (5th ed., Bonn, 1882) and *Etymologisches Wörterbuch der romanischen Sprachen* (4th ed., Bonn, 1878); W. Spanish Literature

The name Spanish in connexion with literature is now generally restricted to works in the Castilian tongue. In the present article it is taken in the wider sense as embracing the literary productions of the whole Iberian Peninsula, with the exceptions of Portugal and of Galicia, the latter of which, as regards language and literature, belongs to the Portuguese domain. Spanish literature thus considered falls into two divisions—Castilian and Catalan.

I. *Castilian Literature.*—Of the Castilian texts now extant none is of earlier date than the 12th century, and very probably none goes farther back than 1150. The text generally accepted as the oldest—the *Mystery of the Magian Kings*, as it is rather inappropriately designated by most historians of literature—is a fragment of a short semi-liturgical play meant to be acted in the church of Toledo on the feast of Epiphany. Manifestly an imitation of the Latin *ludi* represented in France during the early years of the 12th century, the Spanish piece cannot have been composed much before 1150.

Heroic Poetry.

The national hero Rodrigo Diaz de Bivar (d. 1099), better known in history by the Arabic surname of the Cid, was celebrated in the vulgar tongue in two poems, neither of which has come down to us in its entirety. The more ancient *cantar*, usually entitled *Poema del Cid*, since it was originally edited (1779) by Tomás Antonio Sanchez, relates in its first part the valiant deeds (*gesta*) of the Cid subsequent to his quarrel with Alphonso VI.; in the second the capture of Valencia, the reconciliation of the hero with the king and the marriage of his daughters with the infantes of Carrión; and in the third the treason of the infantes, the vengeance of the Cid, and the second marriage of his daughters with the infantes of Navarre and Aragon. The narrative of the last years of the Cid, which closes the epic, is much curtailed. Whilst in the *Poema* the Cid appears as the loyal vassal, deploring the necessity of separating from his king, the Cid of the second poem, *Crônica rimada del Cid*, is almost a rebel and at least a refractory vassal who dares treat his sovereign as an equal. The portion of the *Crônica* which has been preserved deals in the main with the youth of Rodrigo; it contains the primitive version of his quarrel with the Count Gomez de Gormaz and the marriage of the slayer with Ximena, the Count's daughter, and also a series of fabulous episodes, such as the Cid's journey to France to fight with the twelve peers of Charlemagne, &c. The *Poema*, which survives in a 14th-century manuscript, belongs to about the middle of the 12th century; the form under which the *Crônica* text has reached us is at least two centuries later; but, on the other hand, several traditions collected by the author bear an incontestable stamp of antiquity. The versification of both poems is irregular. Normally this epic measure may be divided into two hemistichs of seven or eight syllables each; but here the lines sometimes fall short of this number and sometimes exceed it; the strophes follow the model of the *laisses* of the French *chansons de geste*—that is, they have a single assonance and vary greatly in extent.

A fragment of an epic poem on the infantes de Lara has been reconstituted from the *Crónica general* by Ramón Menéndez Pidal (1896); if similar poems existed on real personages like Roderick, or mythical heroes like Bernardo del Carpio, they have not survived. Still the frequent allusions in the chronicles to the narratives of the *juglares* suggest that Castilian heroic poetry was richer than the scarcity of the monuments now extant would lead us to believe. Fernán González, first independent count of Castile (10th century), has alone been celebrated in a poem composed (about 1250 or later) in single-rhyme quatrains.

Poems of 13th Century.

With the heroic poetry which takes its themes from the national history and legends, there grew up in the 13th century a school of religious and didactic poetry, the most eminent representative of which is Gonzalo de Berceo (1180?–1246?). This poet, born at Berceo (Logroño), composed several lives of Spanish saints, and other devotional poems, such as the *Miracles* and the *Praises of the Virgin*. Berceo calls his poems *prosa*, *decir*, *dictado*, indicating thereby that he intended them to be read and recited, not sung like the *cantares*. They are written in single-rhyme quatrains and in verses of twelve to fourteen syllables, according as the ending of each hemistich is masculine or feminine. In the same metre were composed, also in the 13th century, two long poems—one on Alexander the Great, the other on Apollonius of Tyre—after Latin and French sources. The author of the first of these poems contrasts his system of versification, which he calls *mester de clerecia*, with the *mester de joglaría* used in heroic poetry, and intended to be sung; and he declares that this single-rhyme quatrain (*curso rimado por la quaderna via*) consists of counted syllables. The composer of *Apolonio* calls this same versification *nueva mestría*. The single-rhyme quatrain, introduced in imitation of the French poetry of the 12th century, became from the time of Berceo and the *Alixandre* and *Apolonio* the regular form in Castilian narrative and didactic poetry, and prevailed down to the close of the 14th century.

To the 13th century are assigned a *Life of St Mary the Egyptian*, translated from the French, perhaps through a Provençal version, and an *Adoration of the Three Kings*, in verses of eight or nine syllables rhyming in pairs (*aa*, *bb*, *cc*, &c.), as well as a fragment of a *Debate between Soul and Body*, in verses of six or seven syllables, evidently an imitation of one of the medieval Latin poems, entitled *Rixa animi et corporis*. The oldest lyric in Castilian, *La Razón feita d'amor*, belongs to the same period and probably derives from a French source; it bears the name of Lope de Moros, who, however, seems to have been merely the copyist. Mention may here also be made of the *cantigas* (songs) of Alphonso the Learned in honour of the Virgin, although, being in the Galician dialect, these properly belong to the history of Portuguese literature.

Poetry of 14th Century.

The 14th century saw the birth of the most original medieval Spanish poet. Juan Ruiz, archpriest of Hita (near Guadalajara), has left us a poem of irregular composition, in which, while reproducing apologues and *dits* from foreign sources, he frequently trusts to his own inspiration. Ruiz celebrates love and woman; his book is of *buen amor*, that is, he shows by his own experience and the example of those whom he follows how a man may become a successful lover. By way of precaution, the poet represents himself as one who has survived his illusions, and maintains that carnal love (*loco amor*) must finally give place to divine love; but this mask of devotion cannot disguise the real character of the work. The *Rimado de palacio* of Pero Lopez de Ayala, chancellor of Castile at the end of the 14th century, does not refer exclusively to court life; the author satirizes with great severity the vices of all classes of laymen and churchmen. Akin to this *Rimado de palacio* are the *proverbios morales* of the Jew Sem Tob of Carrión, dedicated to Peter the Cruel (1350 to 1369). The *Poema de Alfonso Onceno*, by Rodrigo Yañez, is a far-off echo of the epical poems, the *laisses* being superseded by octo-syllabic lines with alternate rhymes. The *General Dance of Death* and a new version of the *Debate between Soul and Body*, both in eight-line strophes of *arte mayor* (verses of twelve syllables), and both imitated from French originals, are usually referred to this period; they both belong, however, to the 15th century.

Romances.

The word "romance" not only signifies in Spain, as in other Romanic countries, the vulgar tongue, but also bears the special meaning of a short epic narrative poem (historic ballad) or, at a later date, a short lyric poem. As regards the form, the "romance" (Spanish *el romance*, in contrast to French, &c., *la romance*) is a composition in long verses of sixteen syllables ending with one assonance; these verses are often wrongly divided into two short lines, the first of which, naturally, is rhymeless. This being the form of the *romance* verse, the *Crónica rimada del Cid*, and even the *Poema* (though in this case the influence of the French alexandrines is perceptible), might be considered as a series of *romances*; and in fact several of the old *romances* of the Cid, which form each an independent whole and were printed as separate poems in the 16th century, are partly to be found in the *Crónica*. Other *romances*, notably those dealing with the heroes of the Carolingian epic, so popular in Spain, or with the legendary figures which Spanish patriotism opposed to the French paladins—as, for example, Bernardo del Carpio, the rival and the conqueror of Roland in Castilian tradition—seem to be detached fragments of the *cantares de gesta* mentioned by Alphonso X. At the close of the 15th century, and especially during the 16th, the *romances*, which had previously passed from mouth to mouth, began to be written down, and afterwards to be printed, at first on broadsheets (*pliegos sueltos*) and subsequently in collections (*romanceros*); these are either general collections, in which *romances* of very different date, character and subject are gathered together, or are collections restricted to a single episode or personage (for example, the *Romancero* *del Cid*). In such *romanceros* the epic verse is usually regarded as octosyllabic and is printed as such; occasionally certain editions divide the *romance* into strophes of four verses (*cuartetas*).

Prose Chronicles, 13th-16th Centuries.

King Alphonso X. (d. 1284), under whose patronage were published the code entitled *Las Siete partidas* and several great scientific compilations (such as the *Libros de astronomía* and the *Lapidario*), was also the founder of Spanish historiography in the vulgar tongue. The *Crónica general*, composed under his direction, consists of two distinct parts: the one treats of universal history from the creation of the world to the first centuries of the Christian era (*La General é grant historia*); the other deals exclusively with the national history (*La Crónica ó Historia de España*) down to the death of Ferdinand III. (1252), father of Alphonso. The main sources of the *Crónica general* are two Spanish ecclesiastical chroniclers of the 13th century—Lucas of Tuy and Rodrigo of Toledo; both wrote in Latin, but their works were early translated into the vernacular. In the *Historia de España*, printed in its true form for the first time in 1906, are collected many legends and occasional references to the songs of the *juglares* (for the purpose, however, of refuting them), the narrative relating to the Cid being partly based on an Arabic text. This portion, as recast in the *Crónica de Castilla* compiled by order of Alphonso XI., was published apart by Juan de Velorado under the title of the *Crónica del Cid* (1512), and has often been reprinted. Alphonso's example bore fruit In the 14th century we find another *Crónica general de España* or *de Castilla*, constructed on the model of the first and embracing the years 1030–1312; next, the *Grant crónica de España* and the *Grant Crónica de los conqueridores*, compiled by command of the grand master of the order of St John of Jerusalem, Juan Fernandez de Heredia (1310–1396), about 1390. Special chronicles of each king of Castile were soon written. Our information is defective regarding the authorship of the chronicles of Alphonso X., Sancho IV., Ferdinand IV. and Alphonso XI.; but the four following reigns—those of Pedro I., Henry II., John I. and Henry III.—were dealt with by Pero Lopez de Ayala; here we recognize the man of literary culture who had acquired some knowledge of ancient history, for the form of the narrative becomes freer and more personal, and the style rises with the thought. Alvar Garcia de Santa Maria and other writers whose names are not recorded probably compiled the chronicle of John II.; the events of Henry IV.'s disastrous reign were related by Diego Enriquez del Castillo and Alfonso Fernândez de Palencia; the triumphs of the Catholic sovereigns Ferdinand and Isabella by Fernando del Pulgar and Andrés Bernâldez. With these royal chronicles should be mentioned some biographies of important persons. Thus in the 15th century the chronicle of Pedro Niño, count of Buelna (1375–1446), by Gutierre Diez de Games; that of Alvaro de Luna, constable of Castile (d. 1453); and a curious book of travels, the narrative of the embassy sent by Henry III. of Castile to Timur in 1403, written by the head of the mission, Ruy González de Clavijo.

Biographies.

Other Prose Works of 13th and 14th Centuries.

The other productions of Castilian prose in the 13th and 14th centuries are for the most part didactic and sententious compositions, which, however, contain illustrations or tales of Eastern origin. The Spanish translation of *Kalila and Dimna*, made direct from an Arabic text, dates from the middle of the 13th century, and the romance of the *Seven Sages* (*Sindibad*), translated under the title of *Libro de los engaños é asayamientos de las mugeres*, is referred to 1253. From the second half of the 13th century the collections of aphorisms, *dits*, apologues and moral tales become very numerous: first of all, versions of the *Secretum secretorum*, attributed in the middle ages to Aristotle, one of which is entitled *Poridat de las poridades*, next the *Proverbios buenos*, the *Bocados de oro* or *Libro de bonium, Rey de Persia* and the *Libro de los gatos*, which is derived from the *Narrationes* of Odo of Cheriton. During the first half of the 14th century the nephew of Alphonso X., the infante Juan Manuel, wrote the various works which place him in the first rank of medieval Spanish prose writers. The best known is the collection of tales, many of them borrowed from Oriental sources, entitled *El Conde Lucanor*; but, besides this contribution to literature, he wrote graver and still more didactic treatises. The knowledge of antiquity, previously so vague, made remarkable progress in the 14th century. Curiosity was awakened concerning certain episodes of ancient history, such as the War of Troy, and Benoît de Sainte-More's poem and the Latin narrative of Guido delle Colonne were both translated. Lopez de Ayala translated, or caused to be translated, Pierre Bersuire's French version of Livy, Boetius and various writings of Isidore of Seville and Boccaccio.

Books of Chivalry.

While the Carolingian cycle is mainly represented in Spain by assonanced *romances*, of which the oldest seem to be fragments of lost poems by the *juglares*, the British cycle (Lancelot, Tristram, Merlin, &c.) is represented almost exclusively by works in prose (see ROMANCE). Those narratives are known only in 15th and 16th century editions, and these have been more or less modified to suit the taste of the time; but it is impossible not to recognize that books such as *El Baladro del sabio Merlin* (1498) and *La Demanda del sancto grial* (1515) presuppose a considerable antecedent literature of which they are only the afterglow. The principal French romances of the Round Table were translated and imitated in Spain and in Portugal as early as the first half of the 14th century at least; of that there is no doubt. And, even if there were not satisfactory testimony on this point, the prodigious development in Spanish literature of the *caballerías*, or "books of chivalry," incontrovertibly derived from fictions of Breton origin, would be proof enough that at an early date the Spaniards were familiar with these romantic tales derived from France. The oldest work of the kind is *El Caballero Cifar*, composed at the beginning of the 14th century, but the first book of real importance in the series of strictly Spanish *caballerías* is the *Amadís de Gaula*. Certain considerations lead one to seek for the unknown author of the first *Amadís* in Portugal, where the romances of the Round Table were more highly appreciated than in Spain, and where they have exercised a deeper influence on the national literature. To Garci Rodríguez de Montalvo, however, falls the honour of having preserved the book by printing it; he made the mistake of diluting the original text and of adding a continuation, *Las Sergas de Esplandián*. Allied to Montalvo's *Amadís* with its supplementary *Esplandián* (1510) are the *Don Florisando* (1510) and the *Lisuarte de Grecia* (1514), the *Amadís de Grecia* (1514), the *Don Florisel de Niquea* (1532–1551), &c., which form what Cervantes called the "Amadis sect." Parallel with the Amadises are the Palmerines, the most celebrated of which are *Palmerín de Oliva* (1511), *Primaleon* (1512), and *Palmerín de Inglaterre*,which was first written in Portuguese by Moraes Cabral. None of those *caballerías* inspired by the *Amadís* were printed or even written before the 16th century, and they bear the stamp of that period; but they cannot be separated from their medieval model, the spirit of which they have preserved. Among the *caballerías* we may also class some narratives derived from the Carolingian epic—the *Historia del emperador Carlomagno y de los doce pares*, a very popular version still reprinted of the French romance of *Fierabras*, the *Espejo de caballerías*, into which has passed a large part of Boiardo's *Orlando innamorato*, the *Historia de la reina Sibilla*, &c.

Poetry of 15th Century.

The first half of the 15th century, or what comes almost to the same thing, the reign of John II. of Castile (1407–1454), is characterized as regards his literature (1) by the development of a court poetry, artificial and pretentious; (2) by the influence of Italian literature on Castilian prose and poetry, the imitation of Boccaccio and Dante, especially of the latter, which introduced into Spain a liking for allegory; and (3) by more assiduous intercourse with antiquity. After the example of the Provençal troubadours whose literary doctrines had made their way into Castile through Portugal and Catalonia, poetry was now styled the *arte de trobar*. The *arte de trobar* is strictly "court" poetry, which consists of short pieces in complicated measures—love plaints, debates, questions and repartees, *motes* with their *glosas*, burlesque and satirical songs—verse wholly "occasional" and deficient in charm when separated from its natural environment. In order to understand and appreciate these pieces they must be read in the collections made by the poets of the time, where each poem throws light on the others. The most celebrated *cancionero* of the 15th century is that compiled for the amusement of his sovereign by Juan Alfonso de Baena; it is, so to say, the official collection of the poetic court of John II., although it also contains pieces by poets of earlier dates. After Baena's collection may be mentioned the *Cancionero de Stúñiga*, which contains the Castilian poems of the *trobadores* who followed Alphonso V. of Aragon to Naples. These *cancioneros*, consisting of the productions of a special group, were succeeded by collections of a more miscellaneous character in which versifiers of very different periods and localities are brought together, the pieces being classed simply according to their type. The earliest genuine *Cancionero general* (though it does not bear the title) is that compiled by Juan Fernández de Constantina, which appears to have been issued from the Valencia press at the beginning of the 16th century; the second, much better known, was published for the first time at Valencia in 1511 by Hernando del Castillo. The other poetic school of the 15th century, which claims to be specially related to the Italians, had as its leaders Juan de Mena, author of the *Coronación* and the *Laberinto de fortuna*, and the marquis of Santillana, Iñigo Lopez de Mendoza, who in his sonnets was, perhaps, the first to imitate the structure of the Italian hendecasyllabics. With those two chiefs, who may be designated *poetas* as distinguished from the *decidores* and the *trobadores* of the *cancioneros*, must be ranked Francisco Imperial, a Genoese by descent, who at a somewhat earlier date helped to acclimatize in Spain the forms of Italian poetry. The marquis of Santillana occupies a considerable place in the literature of the 15th century not only by reason of his poems, but through the support he afforded to all the writers of his time, and the impulse he gave to the study of antiquity and to the labours of translators. In the next generation the most prominent figures are Gomez Manrique and Jorge Manrique, the latter of whom has produced a short poem which is a masterpiece.

With the exception of the chronicles and some *caballerías* the prose of the 15th century contains little that is striking.

Prose of 15th Century.

The translation of Virgil by Enrique de Villena is ponderous and shows no advance on the versions of Latin authors made in the previous century. A curious and amusing book, full of details about Spanish manners, is the *Corbacho* (1438) of the archpriest of Talavera, Alfonso Martinez de Toledo, chaplain to King John II.; the *Corbacho* belongs to the numerous family of satires against women, and this title, by which it is commonly known—borrowed from a work of Boccaccio's, with which it has otherwise nothing in common—indicates that he has not spared them.

Dramatic Literature.

The ancient liturgical Spanish theatre is known to us only by fragments of the play of the *Magian Kings*, already mentioned; but certain regulations given in the *Siete partidas* (compiled between 1252 and 1257) prove that such a theatre existed, and that at the great festivals, such as Christmas, Epiphany and Easter, dramatic representations were given in church. These representations, originally a simple commentary on the liturgy, were gradually adulterated with buffoonery, which frequently brought down the censure of the clergy. Alphonso X. even thought it necessary to forbid the "clerks" playing *juegos de escarnios*, and permitted in the sanctuary only dramas destined to commemorate the principal episodes of the life of Christ. Of all the Church festivals, the most popular in Spain was that of Corpus Christi instituted by Urban IV. in 1264. At an early date the celebration of this festival was accompanied with dramatic performances intended to explain to the faithful the eucharistic mystery. These dramas, called *autos sacramentales*, acquired more and more importance; in the 17th century, with Calderón, they become grand allegorical pieces, regular theological dissertations in the form of dramas. To the *auto sacramental* corresponds the *auto al nacimiento*, or drama of the Nativity. In Spain, as elsewhere, the secular theatre is a product of the religious theatre. Expelled from the Church, the *juegos de escarnios* took possession of the public squares and there attained free development; ceasing to be a mere travesty of dogma, they developed into a drama whose movement is no longer determined by the liturgy, and whose actors are borrowed from real life in Spanish society. This new theatre begins towards the close of the 15th century, with the pastoral pieces of Juan del Encina, which, after Virgil's example, he calls *églogas*. Genuine shepherds are the interlocutors of these bucolics, into which are also sometimes introduced students, and Lucas Fernández, a contemporary and pupil of Encina's, introduces gentlemen and soldiers. A book which, strictly speaking, does not belong to the theatre, the *Tragicomedia de Calixto y Melibea*, much better known as *La Celestina*, caused the new theatre, still rudimentary in the attempts of the school of Encina, to make a step onwards. This astonishing novel taught the Spaniards the art of dialogue, and for the first time exhibited persons of all classes of society (particularly the lowest) speaking in harmony with their natural surroundings. The progress caused by the *Celestina* may be estimated by means of the *Propaladia* of Bartolomé de Torres Naharro, a collection of pieces represented at Rome in presence of Leo X. Torres Naharro is thought to have borrowed from France the division of the play into "days" (*jornadas*); shortly after Naharro we find the comedy of manners in Lope de Rueda, whose dramatic work is composed of regular comedies constructed on the model of Italian authors of the beginning of the 16th century, and also of little pieces intended for performance in the intervals between the larger plays (*entremeses* and *pasos*), some of which are models of sprightly wit. Some of Naharro's, and especially of Rueda's, pieces foreshadow the comedy of intrigue, which is emphatically the type of the classic stage. But to reach Lope de Vega, the Spanish stage had to be enlarged in relation to national history. A poet of Seville, Juan de la Cueva, first brought on the boards subjects such as the exploits of the Cid, Bernardo del Carpio, and others, which had previously been treated of only in the *romances*. To a poet called Berrio, of whose work nothing has been preserved, are attributed the *comedias* of Moors and Christians, in which were represented famous episodes of the age-long struggle against the infidel. And it was at this period (1585) that Cervantes experimented in the drama; in his *Tratos de Argel* he gives us a picture of galley-life, recollections of his long captivity in Algiers. There is no need to linger over the attempts at tragedy of the ancient type by Jerónimo Bermúdez, Cristóbal de Virués, Lupercio Leonardo de Argensola, &c., the only successful specimen of which is the *Numancia* of Cervantes; these works, mere exercises in style and versification, remained without influence on the development of the Spanish stage. The pre-classic period of this stage is, as regards dramatic form, one of indecision. Some write in prose, like Rueda; others, like Naharro, show a preference for the *redondillas* of popular poetry; and there are those again who, to elevate the style of the stage, versify in hendecasyllabics. Hesitation is also evident as to the mode of dividing the drama. At first a division into five acts, after the manner of the ancients, is adopted, and this is followed by Cervantes in his early pieces; then Juan de la Cueva reduced the five acts to four, and in this he is imitated by most poets till the close of the 16th century (Lope de Vega himself in his youth composed pieces in four acts). Francisco de Avendaño divided his *Florisea* into three acts as early as 1551, but his example was not followed till about forty years later, when this division was generally adopted in all dramatic works—with the exception of short pieces like the *loa* (prologue), the *entremés*, the *paso*, the *baile* (different kinds of *entr'acte*).

The golden age of Spanish literature belongs to the 16th and 17th centuries, extending approximately from 1550 to 1650. Previous to the reign of the Catholic sovereigns there exists, strictly speaking, only a Castilian literature, largely influenced by imitation first of France and then of Italy; the union of the two crowns of Aragon and Castile, and afterwards the advent of the house of Austria and the king of Spain's election as emperor, achieved the political unity of Spain and the unity of Spanish literature. After the death of Philip IV. (1665) the light went out; the nation, exhausted by wars and bad administration, produced nothing; its literary genius sank in the general decline, and Spain was destined ere long to fall again under the influence of France, to which she had submitted during the first period of the middle ages. In the 16th and 17th centuries the literature was eminently national. Yet in certain kinds of literature the Spaniards continued to seek models abroad.

Classic Age, 16th and 17th Centuries.

Lyric poetry, especially that of the more ambitious order, is always inspired by the Italian masters. An irresistible tendency leads the Spanish poets to rhyme in hendecasyllabics—as the marquis of Santillana had formerly done, though his attempts had fallen into oblivion—and to group their verses in tercets, octaves, sonnets and *canciones* (*canzoni*). Juan Boscán, Garcilaso de la Vega and Diego Hurtado de Mendoza are the recognized chiefs of the school *al itálico modo*, and to them belongs the honour of having successfully transplanted to Spain these different forms of verse, and of having enriched the poetic language of their country. The defects of Boscán and Mendoza (such as certain faults of rhythmic accentuation) were corrected by their disciples Gutierre de Cetina, Gregorio Silvestre, Hernando de Acuña, by the poets of the so-called school of Seville, headed by Fernando de Herrera and also by those of the rival school of Salamanca, rendered famous mainly by the inspired poetry of Luis Ponce de León. Against these innovators the poets, faithful to the old Castilian manner, the rhymers of *redondillas* and *romances*, held their own; under the direction of Cristòbal de Castillejo, they carried on a fierce war against the "Petrarchists." But by the last third of the 16th century the triumph of the new Italian school was assured, and no one any longer thought of reproaching it for its exotic flavour. Still at this period there was a schism between the higher poetry and the other varieties: in the former only the hendecasyllabic and the heptasyllabic (*quebrado*) were employed, while the popular poets, or those who affected a more familiar tone, preserved the national metres. Almost all the poets, however, of the 16th and 17th centuries tried their powers in both kinds of versification, using them in turn according to the nature of their subjects. Thus Lope de Vega, first of all, who wrote *La Dragontea* (1598), *La Hermosura de Angélica* (1602), *La Jerusalem conquistada* (1609), in Italian verses and in octaves, composed his long narrative poem on Isidore, the patron of Madrid (1599), in *quintillas* of octosyllabic verse, not to mention a great number of *romances*. As regards this last form, previously disdained by artistic poets, Lope de Vega gave it a prestige that brought it into favour at court. A host of poets were pleased to recast the old *romances* or to compose new ones. The 17th century, it may be said, is characterized by a superabundance of lyric poetry, to which the establishment of various literary academies contributed. Of this enormous mass of verses of all sorts little still survives; the names of most of the versifiers must be omitted, and in addition to those already cited it will be sufficient to mention Góngora and Quevedo. Góngora is especially famous as the founder of the "cultist" school, as the introducer into Castilian poetry of a periphrastic style, characterized by sonorous diction and artificial arrangements of phrase. The Spaniards have given the name of *culto* to this eccentric style, with its system of inversions based on Latin syntax; but Góngora, a poet of really great powers, had begun better, and as often as he is contented with *romances* he finds true poetic accents, ingenious ideas and felicitous expressions. Quevedo, much greater in prose than in verse, displays real power only in satire, epigram and parody. There is in some of his serious pieces the stuff of a Juvenal, and his satiric and burlesque *romances*, of which several are written in slang (*germanía*), are in their way little masterpieces. Another commonplace of Spanish poetry at this period was epic poetry after the style of Tasso's *Gerusalemme*. These interminable and prosaic compositions in *octavos reales* do not approach their model; none of them can even be compared in style, elevation of thought and beauty of imagery, to Camoens's *Lusiadas*. They are in reality rhymed chronicles, and consequently, when the author happens to have taken part in the events he narrates, they have a genuine historical interest. Such is the case with Alonso de Ercilla's *Araucana*, of which it may be said that it was written less with a pen than with a pike. In burlesque poetry the Spaniards have been more successful: *La Gatomaquia* of Lope de Vega, and *La Moschea* of Villaviciosa (d. 1658) are agreeable examples of witty invention.

Lyric Poetry.

The departments of imaginative literature in which the genius of the new Spanish nation revealed itself with most vigour and originality are the *novela* and the drama. By *novela* must be understood the novel of manners, called *picaresca* (from *pícaro*, a rogue or "picaroon") because of the social status of the heroes of those fictions; and this type of novel is a Spanish invention. The pastoral romance, on the other hand—the best-known examples of which are the *Diana* of Jorge de Montemayor, continued by Alonso Perez and Gaspar Gil Polo, the *Galatea* of Cervantes, and the *Arcadia* of Lope de Vega—as well as the novel of adventure begun by Cervantes in his *Novelas exemplares*, and cultivated after him by a host of writers, is directly derived from Italy. The *Arcadia* of Sannazaro is the source of the *Diana* and of all its imitations, just as the Italian *novellieri* are the masters of most Spanish *novelistas* of the 17th century. The picaresque novel starts in the middle of the 16th century with the *Vida de Lazarillo de Tormes, sus fortunas y adversidades*; the impetus was given, and the success of *Lazarillo* was so great that imitators soon appeared. In 1599 Mateo Alemán published the first part of the adventures of another picaroon, Guzman de Alfarache; before he could issue the sequel (1604) he was anticipated (1602) by an unscrupulous rival, whose continuation was on a lower plane. Quite unlike that of the *Lazarillo*, the style of Mateo Alemán is eloquent, full, with long and learned periods, sometimes diffuse. Nothing could be more extravagant and more obscure than the history of Justina the beggar woman (*La Pícara Justina*) by Francisco Lopez de Ubeda (1605), which is generally (but perhaps wrongly) said to be a name assumed by the Dominican Andrés Perez. A long series of similar tales continued to be published by writers of considerable merit (see PICARESQUE NOVEL).

Fiction.

By degrees the picaresque romance was combined with the novel of Italian origin and gave rise to a new type—half novel of manners, half romance of adventure—of which the characteristic example appears to be the *Marcos de Obregón* (1618) of Vicente Martinez Espinel, one of the best written works of the 17th century. To the same class belong almost all the novels of Alonso Jerónimo de Salas Barbadillo, Luiz Velex de Guevara and Francisco Santos's popular pictures of life in Madrid, *Dia y noche de Madrid* (1663), *Periquillo, el de las gallineras*, &c. On the other hand, the novels of Tirso de Molina (*Los Cigarrales de Toledo*, 1624), Perez de Montalbán (*Para todos*, 1632), Maria de Zayas (*Novelas*, 1635–1647), are more in the manner of the *Novelas exemplares* of Cervantes, and consequently of the Italian type. Among the so-called historical romances one only deserves to be mentioned—the *Guerras civiles de Granada* (1595–1604) by Ginés Perez de Hita, which deals with the last years of the kingdom of Granada and the insurrection of the Moors of the Alpujarras in the time of Philip II. *Don Quixote* (1605–1615), the masterpiece of Cervantes, is too great a work to be treated with others; and, moreover, it does not fall strictly within the limits of any of the classes just mentioned. If it has to be defined, it may be described as the social romance of

16th and 17th century Spain. Cervantes undoubtedly owed much to his predecessors, notably to the few picaresque romancers who came before him, but he considerably enlarged the scope of the type and strengthened the framework of the story by a lofty moral idea. His main purpose was not so much to ridicule the books of chivalry, which were already out of fashion by his time, but to show by an example pushed to absurdity the danger of those prejudices of pure blood and nobler race with which three-fourths of the nation were imbued, and which, by the scorn of all useful labour which they involved, were destined to bring Spain to ruin. The lesson is all the more effective, as Cervantes's *hidalgo*, although ridiculous, was not put beyond the pale of the reader's sympathy, and the author condemns only the exaggeration of the chivalrous spirit, and not true courage and devotion when these virtues have a serious object. What happened to *Guzman de Alfarache* happened to *Don Quixote*. In 1614 a spurious second part of the adventures of Don Quixote made its appearance; Cervantes was thus roused from inactivity, and the following year gave to the world the true second part, which instantly eclipsed Avellaneda's imitation.

Drama of 17th Century.

The stage in the 17th century in some measure took the place of the *romances* of the previous age; it is, as it were, the medium of all the memories, all the passions, and all the aspirations of the Spanish people. Its style, being that of the popular poetry, made it accessible to the most illiterate classes, and gave it an immense range of subject. The Bible, the lives of the martyrs, national traditions, the chronicles of Castile and Aragon, foreign histories and novels, even the daily incidents of contemporary Spanish life, the escapades and nightly brawls of students, the gallantries of the Calle Mayor and the Prado of Madrid, balcony escalades, sword-thrusts and dagger-stabs, duels and murders, fathers befooled, jealous ladies, pilfering and cowardly valets, inquisitive and sprightly waiting-maids, sly and tricky peasants, fresh country girls—all are turned to dramatic account. The enormous mass of plays with which the literature of this period is inundated may be divided into two great classes—secular and religious; the latter may be subdivided into (1) the liturgical play, *i.e.* the *auto* either *sacramental* or *al nacimiento*, and (2) the *comedia divina* or the *comedia de santos*, which has no liturgical element, and differs from a secular play only in the fact that the subject is religious and frequently, as one of the names indicates, derived from the biography of a saint. In the secular drama, classification might be carried almost to any extent if the nature of the subject be taken as the criterion. It will be sufficient to distinguish the *comedia* (*i.e.* any tragic or comic piece in three acts) according to the social types brought on the stage, the equipment of the actors, and the artifices resorted to in the representation We have (1) the *comedia de capa y espada*, which represents everyday incident, the actors belonging to the middle class, simple *caballeros*, and consequently wearing the garb of ordinary town life, of which the chief items were the cloak and the sword; and (2) the *comedia de teatro* or *de ruido*, or again, *de tramoya* or *de aparencias* (*i.e.* the theatrical, spectacular or scenic play), which has kings and princes for its dramatis personae and makes a great display of mechanical devices and decorations. Besides the *comedia*, the classic stage has also a series of little pieces subsidiary to the play proper: the *loa*, or prologue; the *entremés*, a kind of interlude which afterwards developed into the *sainete*; the *baile*, or ballet accompanied with singing; and the *zarzuela*, a sort of operetta thus named after the royal residence of La Zarzuela, where the kings of Spain had a theatre. As to the dramatic poets of the golden age, even more numerous than the lyric poets and the romancers, it is difficult to group them. All are more or less pupils or imitators of the great chief of the new school, Lope Felix de Vega Carpio; everything has ultimately to be brought back to him whom the Spaniards call the "monster of Nature." Among Lope's contemporaries only a few poets of Valencia—Gaspar Honorat de Aguilar (1561–1623), Francisco Tárrega, Guillen de Castro, the author of the *Mocedades del Cid* (from which Corneille derived his inspiration)—formed a small school, as it were, somewhat less subject to the master than that of Madrid, which could only win the applause of the public by copying as exactly as possible the manner of the great initiator. Lope left his mark on all varieties of the *comedia*, but did not attain equal excellence in all. He was especially successful in the comedy of intrigue (*enredo*), of the *capa y espada* class, and in dramas whose subjects are derived from national history. His most incontestable merit is to have given the Spanish stage a range and scope of which it had not been previously thought capable, and of having taught his contemporaries to invent dramatic situations and to carry on a plot. It is true he produced little that is perfect: his prodigious fecundity and facility allowed him no time to mature his work; he wrote negligently, considered the stage an inferior department, good for the *vulgo*, and consequently did not judge it worthy of the same esteem as lyric or narrative poetry modelled on the Italians. Lope's first pupils exaggerated some of his defects, but, at the same time, each, according to his own taste, widened the scope of the *comedia*. Antonio Mira de Amescua and Luis Velez de Guevara were successful, especially in tragic histories and *comedias divinas*. Gabriel Téllez, better known under the pseudonym of Tirso de Molina, one of the most flexible, ingenious and inventive of the dramatists, displayed no less talent in the comedy of contemporary manners than in historical drama. *El Burlador de Sevilla* (*Don Juan*) is reckoned his masterpiece; but he showed himself a much greater poet in *El Vergonzoso en palacio*, *Don Gil de las Calzas Verdes* and *Marta la Piadosa*. Finally Juan Ruiz de Alarcón the most serious and most observant of Spanish dramatic poets, successfully achieved the comedy of character in *La Verdad sospechosa*, closely followed by Corneille in his *Menteur*. Most of the remaining play-writers did little but increase the number of *comedias*; they added nothing to the real elements of the drama. The second epoch of the classical drama is represented mainly by Pedro Calderón de la Barca, the Spanish dramatist who has obtained most celebrity abroad, where his pieces have been much studied and admired (perhaps extravagantly). It is Calderón who first made honour, or more correctly the point of honour, an essential motive in the conduct of his personages (e.g. *El Médico de su honra*); it is he also who made the *comedia de capa y espada* uniform even to monotony, and gave the comic "part" of the *gracioso* (confidential valet of the *caballero*) a rigidity which it never previously possessed. There is depth and poetry in Calderón, but also vagueness and bad taste. His most philosophic drama, *La Vida es sueño*, is a bold and sublime idea, but indistinct and feebly worked out; his *autos sacramentales* give evidence of extensive theological knowledge and dexterity in dramatizing abstractions. Calderón was imitated, as Lope had been, by exaggerating his manner and perverting his excellences. Two contemporaries deserve to be cited along with him—Francisco de Rojas Zorilla, author of the fine historic play *Del Rey abajo ninguno*, and Augustín Moreto, author of some pleasant comedies. Among those who worked in a less ambitious vein, mention must be made of Luis Quiñones de Benavente, a skilful writer of *entreméses*.

History.

A new manner of writing appears with the revival of learning; the purely objective style of the old chroniclers, accumulating one fact after another, without showing the logical connexion or expressing any opinion on men or things, began to be thought puerile. An attempt was made to treat the history of Spain in the manner of Livy, Sallust, and Tacitus, whose methods of narration were directly adopted. The 16th century, however, still presents certain chroniclers of the medieval type, with more erudition, precision and the promise of a critical faculty. *La Crónica general de España*, by Ambrosio de Morales; the *Compendio historial* of Estéban de Garibay; and the *Historia general de las Indias occidentales*, by Antonio de Herrera, are, so far as style is concerned, continuations of the last chronicles of Castile. Jerónimo de Zurita is emphatically a scholar; no one in the 16th century knew as he did how to turn to account documents and records for the purpose of completing and correcting the narratives of the ancient chronicles; his *Anales de la corona de Aragón* is a book of great value, though written in a laboured style. With Juan de Mariana history ceases to be a mere compilation of facts or a work of pure erudition, and becomes a work of art. The *Historia de España* by the celebrated Jesuit, first written in Latin (1592) in the interest especially of foreigners, was afterwards rendered by its author into excellent Castilian; as a general survey of its history, well planned, well written and well thought out, Spain possesses nothing that can be compared with it. Various works of less extent—accounts of more or less important episodes in the history of Spain—may take their place beside Mariana's great monument: for example, the *Guerra de Granada*, by Diego Hurtado de Mendoza (a history of the revolt of the Moors of the Alpujarras under Philip II.), written about 1572, immediately after the events, but not published till 1627; the narrative of the expedition of the Catalans in the Morea in the 14th century, by Francisco de Moncada (d. 1635); that of the revolt of the same Catalans during the reign of Philip IV., by Francisco Manuel de Mello, a Portuguese by birth; and that of the conquest of Mexico by Antonio de Solís. Each of these writers was more or less inspired by some Latin author, one preferring Livy, another Sallust, &c. Most of these imitations are somewhat stilted, and their artificiality in the long run proves as fatiguing as the heaviness of the medieval chroniclers. On the other hand, the historians of the wars of Flanders, such as Carlos Coloma, Bernardino de Mendoza, Alonso Vazquez and Francisco Verdugo, are less refined, and for that very reason are more vivid and more capable of interesting us in the struggle of two races so foreign to each other and of such different genius. As for the accounts of the transatlantic discoveries and conquests, they are of two kinds—either (1) memoirs of the actors or witnesses of those great dramas, as, *e.g.* the *Historia verdadera de la conquista de la nueva España*, by Bernal Diaz del Castillo (1492–1581), one of the companions of Cortés, and the *Historia de las Indias*, by Bartolomé de las Casas, the apostle of the Indians; or (2) works by professional writers, such as Francisco Lopez de Gómara, official historiographers who wrote in Spain on information sent to them from the newly-discovered lands.

Letter Writers.

Letter writers, a rather numerous body in Spanish literature, are nearly related to the historians; in fact, letters written to be read by others than the persons addressed, or in any case revised afterwards, are only a method of writing history in a familiar style. Fernando del Pulgar appended to his *Claros varones* a series of letters on the affairs of his time; and in the 16th century Antonio de Guevara (d. 1544) collected, under the title of *Epístolas familiares*, his correspondence with his contemporaries, which throws a great light on the early part of the reign of Charles V., although it must be used with caution because of the numerous recasts it has undergone. A celebrated victim of Philip II., Antonio Perez (d. 1611), revenged himself on his master by relating in innumerable letters, addressed during his exile to his friends and protectors, all the incidents of his disgrace, and by selling to the ministers of France and England the secrets of the Spanish policy in which he had a hand; some of these letters are perfect specimens of urbane gallantry.

Philosophy.

Philosophy is rather poorly represented in the 16th and 17th centuries in the literature of the vernacular. The greater number of the Spanish thinkers of this epoch, whatever the school to which they belonged—scholastic, Platonic, Aristotelian or independent—wrote in Latin. Ascetic and mystical authors alone made use of the vulgar tongue for the readier diffusion of their doctrine among the illiterate, from whose ranks many of their disciples were recruited.

Mysticism.

Luis de Granada (1504–1588), Luis Ponce de León (1528–1598), Teresa de Jesús (1515–1582), Pedro Malón de Chaide and St John of the Cross are the brighter lights of this class of writers. Some of their books, like the *Guia de pecadores* of Luis de Granada, the autobiography of St Theresa, and Malón de Chaide's *Conversion of the Magdalen* (1588), have obtained a lasting success beyond the limits of the Peninsula, and have influenced the development of mysticism in France. The Spanish mystics are not only remarkable for the depth or subtlety of their thoughts and the intensity of the divine love with which they are inspired; many of them are masters of style, and some, like St John of the Cross, have composed verses which rank with the most sublime in the language. A notable fact is that those who are regarded as illuminati profess the most practical ideas in the matter of morality.

Moralists.

Nothing is more sensible, nothing less ecstatic, than the manual of domestic economy by Luis de León—*La Perfecta casada*. Lay moralists are numerous in the 16th and 17th centuries. Some write long and heavy treatises on the art of governing, the education of princes, the duties of subjects, &c. Pedro Fernandez de Navarrete's *Conservación de monarquias*, Diego de Saavedra Fajardo's *Idea de un príncipe cristiano*, Quevedo's *La Política de Dios y gobierno de Cristo*, give a correct idea of the ability which the Spaniards have displayed in this kind of didactic literature—ability of no high order, for the Spaniard, when he means to expound a doctrine, loses himself in distinctions and easily becomes diffuse, pedantic and obscure. But there is a kind of morality in which he indubitably excels, namely, in social satire, which, under all its forms—dialogue and dream in the style of Lucian, epistle after the manner of Juvenal, or pamphlet—has produced several masterpieces and a host of ingenious, caustic and amusing compositions. Juan de Valdés (d. 1541), the most celebrated of the Spanish Protestants, led the way with his *Diálogo de Murcurio y Carón*, where the great political and religious questions of the first half of the 16th century are discussed with admirable vigour and freedom. The most eminent author in the department of social satire, as in those of literary and political satire, is Quevedo. Nothing escapes his scrutinizing spirit and pitiless irony. All the vices of contemporary society are remorselessly pilloried and cruelly dissected in his *Sueños* and other short works. While this great satirist, in philosophy a disciple of Seneca, imitates his master even in his diction, he is none the less one of the most vigorous and original writers of the 17th century. The only serious defect in his style is that it is too full, not of figures and epithets, but of thoughts. His phrases are of set purpose charged with a double meaning, and we are never sure on reading whether we have grasped all that the author meant to convey. *Conceptism* is the name that has been given to this refinement of thought, which was doomed in time to fall into ambiguity; it must not be confounded with the *cultism* of Góngora, the artifice of which lies solely in the choice and arrangement of words. This new school, of which Quevedo may be regarded as the founder, had its Boileau in the person of Baltasar Gracián, who published his *Agudeza y arte de ingenio* (1642), in which all the subtleties of conceptism are reduced to an exact code. Gracián, who had the gift of sententious moralizing rather than of satire, produced in his *Criticón* animated pictures of the society of his own day, while he also displayed much ingenuity in collections of political and moral aphorisms which have won him a great reputation abroad.

18th Century.

Spanish thought as well as public spirit and all other forms of national activity began to decline towards the close of the 17th century. The advent of the house of Bourbon, and the increasing invasion of French influence in the domain of politics as well as in literature and science, frustrated the efforts of a few writers who had remained faithful to the pure Spanish tradition. In the hands of the second-rate imitators of Calderón the stage sank lower and lower; lyric poetry, already compromised by the affected diction of Góngora, was abandoned to rhymesters who tried to make up by extravagance of style for poverty of thought. The first symptoms, not of a revival, but of a certain resumption of intellectual production, appear in the department of linguistic study. In 1714 there was created, on the model of the French academies, La Real Academia Española, intended to maintain the purity of the language and to correct its abuses. This academy set itself at once to work, and in 1726 began the publication of its dictionary in six folio volumes, the best title of this association to the gratitude of men of letters. The *Gramática de la lengua castellana*, drawn up by the academy, did not appear till 1771. For the new ideas which were introduced into Spain as the result of more intimate relations with France, and which were in many cases repugnant to a nation for two centuries accustomed to live a self-contained life, it was necessary that authoritative sanction should be found. Ignacio de Luzán, well read in the literatures of Italy and France, a disciple of Boileau and the French rhetoricians, yet not without seme originality of his own, undertook in his *Poëtica* (1737) to expound to his fellow countrymen the rules of the new school, and, above all, the principle of the famous "unities" accepted by the French stage from Corneille's day onward. What Luzán had done for letters, Benito Feyjoo, a Benedictine of good sense and great learning, did for the sciences. His *Teatro crítico* and *Cartas erúditas y curiosas*, collections of dissertations in almost every department of human knowledge, introduced the Spaniards to the leading scientific discoveries of foreign countries, and helped to deliver them from many superstitions and absurd prejudices. The study of the ancient classics and the department of learned research in the domain of national histories and literatures had an eminent representative in Gregorio Mayáns y Siscar (1699–1781), who worthily carried on the great traditions of the Renaissance; besides publishing good editions of old Spanish authors, he gave to the world in 1757 a *Retórica* which is still worth consulting, and a number of learned memoirs. What may be called the *littérature d'agrément* did not recover much lost ground; it would seem as if the vein had been exhausted. Something of the old picaresque novel came to life again in the *Fray Gerundio* of the Jesuit Isla, a biographical romance which is also and above all—to the detriment, it is true, of the interest of the narrative—a satire on the follies of the preachers of the day.

Romance.

The lyric poetry of this period is colourless when compared with its variegated splendour in the preceding century. Nevertheless one or two poets can be named who possessed refinement of taste, and whose collections of verse at least show respect for the language. At the head of the new school is Menéndez Valdés, and with him are associated Diego González (1733–1794), José Iglesias de la Casa (1748–1791), known by his *letrillas*, Cienfuegos, and some others. Among the verse writers of the 18th century who produced odes and didactic poetry it is only necessary to mention Leandro Fernández de Moratín and Quintana, but the latter belongs rather to the 19th century, during the early part of which he published his most important works. The poverty of the period in lyric poetry is even exceeded by that of the stage. No kind of comedy or tragical drama arose to take the place of the ancient *comedia*, whose platitudes and absurdities of thought and expression had ended by disgusting even the least exacting portion of the public. The attempt was indeed made to introduce the comedy and the tragedy of France, but the stiff and pedantic adaptations of such writers as the elder Moratín, Agustín de Montiano y Luyando (1697–1764), Tomás de Iriarte, Garcia de la Huerta and the well-known economist Gaspar de Jovellanos failed to interest the great mass of playgoers. The only dramatist who was really successful in composing on the French pattern some pleasant comedies, which owe much of their charm to the great purity of the language in which they are written, is Leandro Fernández de Moratín. It has to be added that the *saineté* was cultivated in the 18th century by one writer of genuine talent, Ramón de la Cruz; nothing helps us better to an acquaintance with the curious Spanish society of the reign of Charles IV. than the interludes of this genial and light-hearted author, who was succeeded by Juan Ignacio González del Castillo.

Poetry.

The struggle of the War of Independence (1808–14), which was destined to have such important consequences in the world of politics, exerted no immediate influence on the literature of Spain. One might have expected as a consequence of the rising of the whole nation against Napoleon that Spanish writers would no longer seek their inspiration from France, and would resume the national traditions which had been broken at the end of the 17th century. But nothing of the sort occurred. Not only the *afrancesados* (as those were called who had accepted the new régime), but also the most ardent partisans of the patriotic cause, continued in literature to be the submissive disciples of France. Quintana, who in his odes preached to his compatriots the duty of resistance, has nothing of the innovator about him; by his education and by his literary doctrines he remains a man of the 18th century. The same may be said of Martínez de la Rosa, who, though less powerful and impressive, had a greater independence of spirit and a more highly trained and classical taste. And when romanticism begins to find its way into Spain and to enter into conflict with the spirit and habits of the 18th century, it is still to France that the poets and prose writers of the new school turn, much more than to England or to Germany. The first decidedly romantic poet of the generation which flourished about 1830 was the duke of Rivas; no one succeeded better in reconciling the genius of Spain and the tendencies of modern poetry; his poem *El Moro expósito* and his drama of *Don Alvaro ó la fuerza del sino* belong as much to the old *romances* and old theatre of Spain as to the romantic spirit of 1830. On the other hand, Espronceda, who has sometimes been called the Spanish Musset, savours much less of the soil than the duke of Rivas; he is a cosmopolitan romantic of the school of Byron and the French imitators of Byron; an exclusively lyric poet, he did not live long enough to give full proof of his genius, but what he has left is often exquisite. Zorilla has a more flexible and exuberant, but much more unequal, talent than Espronceda, and if the latter has written too little it cannot but be regretted that the former should have produced too much; nevertheless, among a multitude of hasty performances, brought out before they had been matured, his *Don Juan Tenorio*, a new and fantastic version of the legend treated by Tirso de Molina and Molière, will remain as one of the most curious specimens of Spanish romanticism. In the dramatic literature of this period it is noticeable that the tragedy more than the comedy is modelled on the examples furnished by the French drama of the Restoration; thus, if we leave out of account the play by García Gutiérrez, entitled *El Trovador*, which inspired Verdi's well-known opera, and *Los Amantes de Teruel*, by Hartzenbusch, and a few others, all the dramatic work belonging to this date recalls more or less the manner of the professional playwrights of the boulevard theatres, while on the other hand the comedy of manners still preserves a certain originality and a genuine local colour. Bretón de los Herreros, who wrote a hundred comedies or more, some of them of the first order in their kind, apart from the fact that their diction is of remarkable excellence, adheres with great fidelity to the tradition of the 17th century; he is the last of the dramatists who preserved the feeling of the ancient *comedia*. Mariano José de Larra, a prose writer of the highest talent, must be placed beside Espronceda, with whom he has several features in common. Caustic in temper, of a keenly observant spirit, remarkably sober and clear as a writer, he was specially successful in the political pamphlet, the *article d'actualité*, in which he ridicules without pity the vices and oddities of his contemporaries; his reputation is much more largely due to these letters than either to his plays or his novel *El Doncel de Don Enrique el Doliente*. With Larra must be associated two other humoristic writers. The first of these is Mesonero Romanos, whose *Escenas matritenses*, although of less literary value than Larra's articles, give pleasure by their good-natured gaiety and by the curious details they furnish with regard to the contemporary society of Madrid. The other is Estébanez Calderon, who in his *Escenas andaluzas* sought to revive the manner of the satirical and picaresque writers of the 17th century; in a uselessly archaic language of his own, tesselated with fragments taken from Cervantes, Quevedo and others, he has delineated with a somewhat artificial grace various piquant scenes of Andalusian or Madrid life. The most prominent literary critics belonging to the first generation of the

19th Century.

century were Alberto Lista (1775–1848), whose critical doctrine may be described as a compromise between the ideas of French classicism and those of the romantic school, and Agustín Durán, who made it his special task to restore to honour the old literature of Castile, particularly its *romances*, which he had studied with ardour, and of which he published highly esteemed collections.

If the struggle between classicists and romanticists continued even after 1830, and continued to divide the literary world into two opposing camps, the new generation—that which occupied the scene from 1840 till about 1868—had other preoccupations. The triumph of the new ideas was assured; what was now being aimed at was the creation of a new literature which should be truly national and no longer a mere echo of that beyond the Pyrenees. To the question whether modern Spain has succeeded in calling into existence such a literature, we may well hesitate to give an affirmative answer. It is true that in every species of composition, the gravest as well as the lightest, it can show works of genuine talent; but many of them are strikingly deficient in originality; all of them either bear unmistakable traces of imitation of foreign models, or show (more or less happily) the imprint of the older literature of the 17th century, to which the historical criticism of Durán and the labours of various other scholars had given a flavour of novelty.

Drama. Foreign influence is most clearly marked in the work of Ventura de la Vega (1807–1865), whose relationship to the younger Moratín, and therefore to Molière, is unmistakable in *El Hombre de mundo* (1845), a piece written after a long apprenticeship spent in translating French plays. Among those who endeavoured to revive the dramatic system established by Lope de Vega were Aureliano Fernández-Guerra y Orbe (1816–1894) and Francisco Sánchez de Castro (d. 1878); the former in *Alonso Cano*, and the latter in *Hermenegildo*, produced examples of ingenious reconstruction, which testified to their scholarship but failed to interest the public permanently. A fusion of early and later methods is discernible in the plays of Adelardo López de Ayala and Tamayo y Baus. Campoamor wrote dramas which, though curious as expressions of a subtle intelligence cast in the form of dialogue, do not lend themselves to presentation, and were probably not intended for the stage. Núñez de Arce in *El Hoz de leña* produced an impressive drama, as well as several plays written in collaboration with Antonio de Hurtado, before he found his true vocation as a lyric poet. The successor of Tamayo y Baus in popular esteem must be sought in José Echegaray, whose earlier plays—such as *La Esposa del vengador* and *En el puño de la espada*—are in the romantic style; in his later works he attempts the solution of social problems or the symbolic drama. Such pieces as *El Gran Golesto*, *El Hijo de Don Juan* and *El Loco dios* indicate a careful study of the younger Dumas and Ibsen. Duing the last few years his popularity has shown signs of waning, and the copious dramatist has translated from the Catalan at least one play by Angel Guimerá (b. 1847). To Echegaray's school belong Eugenio Sellés (b. 1844), author of *El Nudo gordiano*, *El Cielo ó el suelo* and *La Mujer de Loth*, and Leopoldo Cano y Masas (b. 1844), whose best productions are *La Mariposa*, *Gloria* and *La Pasionaria*, an admirable example of concise and pointed dialogue. Mention must also be made of José Felíu y Codina (1843–1897), a Catalan who wrote two vigorous plays entitled *La Dolores* and *María del Carmen*; Joaquín Dicenta (b. 1860), whose *Juan José* showed daring talent; and especially Jacinto Benavente (b. 1866), a dramatist whose mordant vigour and knowledge of stage-effect is manifest in *La Comida de las fieras* and *Rosas de otoño*. In a lighter vein much success has attended the efforts of Miguel Echegaray (b. 1848), whose buoyant humour is in quaint contrast with his brother's sepulchral gloom, and Vital Aza (b. 1851) and Ricardo de la Vega (b. 1858) deserve the popularity which they have won, the first by *El Señor Cura* and the second by *Pepa la frescachona*, excellent specimens of humorous contrivance. But the most promising writers for the Spanish stage at the present time are Serafin Alvarez Quintero (b. 1871) and his brother Joaquín (b. 1873), to whose collaboration are due *El Ojito derecho* and *Abanicos y panderetes*, scenes of brilliant fantasy which continue the tradition of witty observation begun by Lope de Rueda.

Poetry. Rivas, Espronceda and Zorrilla owe more to foreign models than either Campoamor or Núñez de Arce. It is true that Campoamor has been described, most frequently by foreign critics, as a disciple of Heine, and undoubtedly Campoamor suggests to cosmopolitan readers something of Heine's concentrated pathos; but he has nothing of Heine's acrimony, and in fact continued in his own semi-philosophic fashion a national tradition of immemorial antiquity—the tradition of expressing lyrical emotion in four or eight lines which finds its most homely manifestation in the five volumes of *Cantos populares españoles* edited by Francisco Rodriguez Marín. No less national a poet was Núñez de Arce, in whose verses, though the sentiment and reflection are often commonplace, the workmanship is of irreproachable finish. His best performance is *Gritos del combate* (1875), a series of impassioned exhortations to concord issued during the civil war which preceded the restoration of the Bourbon dynasty. An ineffectual politician, Núñez de Arce failed in oratory, but produced a permanent political impression with a small volume of songs. He wrote much in the ensuing years, and though he never failed to show himself a true poet he never succeeded in repeating his first great triumph—perhaps because it needed a great national crisis to call forth his powers. He found an accomplished follower in Emilio Pérez Ferrari (b. 1853), whose *Pedro Abelardo* and *Dos cetros y dos almas* recall the dignity but not the impeccability of his model. Another pupil in the same school was José Velarde (d. 1892), whose best work is collected in *Voces del alma*, some numbers of which are indications of a dainty and interesting, if not virile, talent. Absorbed by commerce, Vicente Wenceslao Querol (d. 1889) could not afford to improvise in the exuberant manner of his countrymen, and is represented by a single volume of poems as remarkable for their self-restraint as for a deep tenderness which finds expression in the *Cartas á María* and in the poignant stanzas *A la muerte de mi hermana Adela*. The temptation to sound the pathetic note so thrillingly audible in Querol's subdued harmonies proved irresistible to Federico Balart (1831–1905), a critic and humorist of repute who late in life astonished and moved the public with a volume of verse entitled *Dolores*, a sequence of elegiacs which bear a slight formal resemblance to *In Memoriam*; but the writer's sincerity was doubtful, and in *Horizontes* the absence of genuine feeling degenerated into fluent fancy and agreeable prettiness. A more powerful and interesting personality was Joaquín María Bartrina (1850–1880), who endeavoured to transplant the pessimistic spirit of Leconte de Lisle to Spanish soil. Bartrina's crude materialism is antipathetic; he is wholly wanting in the stately impassability of his exemplar, and his form is defective; but he has force, sincerity and courage, and the best verses in *Algo* (1876) are not easily forgotten. The *Andantes y allegros* and *Cromos y acuarelas* of Manuel Reina (1856–1905) have a delightful Andalusian effusiveness and metrical elegance, which compensate for some monotony and shallowness of thought. Manuel del Palacio (1832–1907) combined imagination and wit with a technical skill equal to that of the French Parnassians; but he frittered away his various gifts, so that but a few sonnets survive out of his innumerable poems. More akin to the English "Lake poets" was Amós de Escalante y Prieto (1831–1902), better known by his pseudonym of "Juan García," whose faculty of poetic description, revealed only to the few who had read his verses in the edition privately circulated in 1890, is now generally recognized. The vein of religious sentiment which runs through Escalante's most characteristic lyrics was also worked by Luis Ramírez Martínez y Guertero (d. 1874), who, under the pseudonym of "Larmig," wrote verses impregnated with Christian devotion as well as with a sinister melancholy which finally led him to commit suicide. The most interesting of the younger poets are provincials by sympathy or residence, if not by birth. Salvador Rueda (b. 1857), in his

Aires españoles, represents the vivid colouring and resonant emphasis of Andalusia; Ramon Domingo Perés (b. 1863), a Cuban by birth but domiciled at Barcelona, strikes a Catalan note in *Musgo* (1902), and substitutes restraint and simplicity for the Castilian sonority and pomp; Vicente Medina (b. 1866) in *Aires murcianos* and *La Canción de la huerta* reproduces with vivid intensity the atmosphere of the Murcian orchard-country; Juan Alcover and Miguel Costa, both natives of Majorca, celebrate their island scenery with luminous picturesqueness of phrase. The roll of Spanish poets may close with the name of José María Gabriel y Galán (d. 1905), whose reputation depends chiefly on the verses entitled "El Ama" in *Castellanas*; Gabriel y Galán was extremely unequal, and his range of subjects was limited, but in *El Ama* he produced a poem which is unsurpassed in modern Spanish poetry. The facility with which verses of a kind can be written in Spanish has made Spain a nest of singing-birds; but the chief names have been already mentioned, and no others need be recorded here.

Fiction. Since 1850 there has been a notable renaissance of the Spanish novel. Fernán Caballero is entitled to an honourable place in literary history as perhaps the first to revive the native realism which was temporarily checked by the romantic movement. In all that concerns truth and art she is superior to the once popular Manuel Fernández y González (d. 1888), of whom it has been said that Spain should erect a statue to him and should burn his novels at the foot of it. A Spanish Dumas, he equals the French author in fecundity, invention and resource, and some of his tales—such as *El Cocinero de su majestad*, *Los Minfies de las Alpujarras* and *Martín Gil*—are written with an irresistible *brio*; but he was the victim of his own facility, grew more and more reckless in his methods of composition, and at last sank to the level of his imitators. Antonio de Trueba followed Fernán Caballero in observing local customs and in poetizing them with a sentimental grace of his own, which attracted local patriots and uncritical readers generally. He had no gift of delineating character, and his plots are feeble; but he was not wanting in literary charm, and went his road of incorrigible optimism amid the applause of the crowd. His contemporary, Pedro Antonio de Alarcón, is remembered chiefly as the author of *El Sombrero de tres picos*, a peculiarly Spanish tale of picaresque malice. Neither Trueba nor Alarcón could have developed into great artists; the first is too falsetto, the second is too rhetorical, and both are too haphazard in execution. Idealizing country life into a pale arcadian idyll, Trueba frowned upon one of his neighbours whose methods were eminently realistic. José María de Pereda is the founder of the modern school of realistic fiction in Spain, and the boldness of his experiment startled a generation of readers accustomed to Fernán Caballero's feminine reticence and Trueba's deliberate conventionality. Moreover, Pereda's reactionary political views—too frequently obtruded in his imaginative work—alienated from him the sympathies of the growing Liberal element in the country; but the power which stamps his *Escenas montañesas* was at once appreciated in the northern provinces, and by slow degrees he imposed himself upon the academic critics of Madrid. So long as Pereda deals with country folk, sailors, fishermen, aspects of sea and land, he deserves the highest praise, for he understands the poor, hits upon the mean between conventional portraiture and caricature, and had the keenest appreciation of natural beauty. His hand was far less certain in describing townsmen; yet it is a mistake to class him as merely a successful landscape painter, for he created character, and continually revealed points of novelty in his descriptions of the common things of life. Pereda is realistic, and he is real. His rival, Juan Valera, is not, in the restricted sense of the word, realistic, but he is no less real in his own wider province; he has neither Pereda's energy nor austerity of purpose, but has a more infallible tact, a larger experience of men and women, and his sceptical raillery is as effective a moral commentary as Pereda's Christian pessimism. In Valera's *Pepita Jiménez* and *Doña Luz*, and in Pereda's *Sotileza*, we have a trio of Spanish heroines who deserve their fame: Pereda's is the more vigorous, full-blooded talent, as Valera's is the more seductive and patrician; yet, much as they differ, both are essentially native in the quality of their genius, system and phrasing. Benito Pérez Galdós gave a new life to the historical novel in his huge series entitled *Episodios nacionales*, a name perhaps suggested by the *Romans nationaux* of Erckmann-Chatrian; but the subjects and sentiment of these forty volumes are intensely local. The colouring of the *Episodios nacionales* is so brilliant, their incident is so varied and so full of interest, their spirit so stirring and patriotic, that the born Spaniard easily forgives their frequent prolixity, their insistence on minute details, their loose construction and their uneven style. Their appeal is irresistible; there is no such unanimous approbation of the politico-religious novels such as *Doña Perfecta*, *Gloria* and *León Roch*, each of which may be regarded as a *roman à thèse*. The quick response of Pérez Galdós to any external stimulus, his sensitiveness to every change in the literary atmosphere, made it inevitable that he should come under the influence of French naturalism, as he does in *Lo Prohibido* and in *Realidad*; but his conversion was temporary, and two forcible novels dealing with contemporary life—*Fortunata y Jacinta* and *Angel Guerra*—mark the third place in the development of a susceptible talent. The true leader of the naturalistic school in Spain is Armando Palacio Valdés, whose faculty of artistic selection was first displayed in *El Señorito Octavio*. Two subsequent works—*Marta y María* and *La Hermana San Sulpicio*—raised hopes that Spain had, in Palacio Valdés, a novelist of the first order to succeed Pereda and Valera; but in *La Espuma* and *La Fe*, two social studies which caused all the more sensation because they contained caricatures of well-known personages, the author followed the French current, ceased to be national and did not become cosmopolitan. His latest books are more original and interesting, though they scarcely fulfil his early promise. Another novelist who for a time divided honours with Palacio Valdés was the lady who publishes under her maiden name of Emilia Pardo Bazán. The powerful, repellent pictures of peasant life and the ethical daring of *Los Pazos de Ulloa* and *La Madre Naturaleza* are set off by graphic passages of description; in later works the author chose less questionable subjects, and the local patriotism which inspires *Insolación* and *De mi tierra* is expressed in a style which secures Emilia Pardo Bazán a high place among her contemporaries. Leopoldo Alas (1851–1901), who used the pseudonym of "Clarín," was better known as a ruthless critic than as a novelist; the interest of his shorter stories has evaporated, but his ambitious novel, *La Regenta*, lives as an original study of the relation between mysticism and passion. Jacinto Octavio Picón (b. 1852), who has deserted novel writing for criticism, displayed much insight in *Lázaro*, the story of a priest who finds himself forced to lay down his orders; this work was naturally denounced by the clerical party, and orthodoxy declared equally against *El Enemigo* and *Dulce y sabrosa*; more impartial critics agree in admiring Picón's power of awakening sympathy and interest, his gift of minute psychological analysis and his exquisite diction. No suspicion of heterodoxy attaches to Manuel Polo y Peyrolón, the author of that charming story *La Tía Levítico*, nor to the Jesuit-Luis Coloma (b. 1851), who obtained a fleeting triumph with *Pequeñeces*, in which the writer satirized the fashionable society of which he had been an ornament before his conversion. Juan Ochoa (d. 1899) showed promise of the highest order in his two short stories, *El Amado discípulo* and *Un alma de Dios* and Angel Ganivet (d. 1898) produced in *Los Trabajos del infatigable creador Pio Cid*, a singular philosophical romance, rich in ideas and felicitous in expression, though lacking in narrative interest. With him may be mentioned Ricardo Macías Picavea (d. 1899), author of *La Tierra de campos*, who died prematurely before his undoubted talent had reached maturity. Of the younger novelists the most notable in reputation and achievement is Vicente Blasco Ibáñez (b. 1866) who began with pictures of Valencian provincial life in *Flor de mayo*, made romance the vehicle of revolutionary propaganda in *La Catedral* and *La Horda*, and shows the influence of Zola in one of his latest books, *La Maja desnuda*. Blasco Ibáñez lacks taste and judgment, and occasional provincialisms disfigure his style; but his power is undeniable, and even his shorter tales are remarkable examples of truthful impressionism. Ramón del Valle-Inclán (b. 1869) tends to preciosity in *Corte de amor* and *Flor de santidad*, but excels in finesse and patient observation; J. Martinez Ruiz (b. 1876) is wittier and weightier in *Las Confesiones de un pequeño filósofo* and the other stories which he publishes under the pseudonym of "Azorin," but he lacks much of Valle-Inclán's picturesque and perceptive faculty; Pío Baroja's restless and picaresque talent finds vigorous but incoherent expression in *El Camino de perfección* and *Aurora roja*, and Gregorio Martínez Sierra (b. 1882) has shown considerable mastery of the difficulties of the short story in *Pascua florida* and *Sol de la tarde*.

The tendency of Spanish historical students is rather to collect the raw material of history than to write history. Antonio Cánovas del Castillo was absorbed by politics to the loss of literature, for his *Ensayo sobre la casa de Austria en España* is ample in information and impartial in judgment; the composition is hasty and the style is often ponderous, but many passages denote a genuine literary faculty, which the author was prevented from developing. The *Historia de los Visigodos*, in which Aureliano Fernández-Guerra y Orbe collaborated with Eduardo de Hinojosa, illuminates an obscure but important period. Francisco Cárdenas (1816–1898) in his *Historia de la propriedad territorial en España* did for Spain much that Maine did for England. Eduardo Pérez Pujol (b. 1830) in his *Historia de las instituciones de la España goda* (1896) supplements the work of Fernández-Guerra and Hinojosa, the latter of whom has published a standard treatise entitled *Historia del derecho romano.* Joaquin Costa's *Estudios ibéricos* (1891) and *Coleclivismo agrario en España* (1898) have been praised by experts for their minute research and exact erudition; but his *Poesía popular española y mitología y literatura celto-hispanas*, in which a most ingenious attempt is made to reconstitute the literary history of a remote period, appeals to a wider circle of educated readers. The monographs of Francisco Codera y Zaidín (b. 1836), of Cesáreo Fernández Duro (1830–1907), of Francisco Fernández y González (b. 1833), of Gumersindo Azcárate (b. 1840), and of many others, such as the Jesuit epigraphist Fidel Fita y Calomé, are valuable contributions to the still unwritten history of Spain, but are addressed chiefly to specialists. Many of the results of these investigators are embodied by Rafael Altamira y Crevea (b. 1866) in his *Historia de España y de la civilización española*, now in progress. Literary criticism in Spain, even more than elsewhere, is too often infected by intolerant party spirit. It was difficult for Leopoldo Alas ("Clarín") to recognize any merit in the work of a reactionary writer, but his prejudice was too manifest to mislead, and his intelligent insight frequently led him to do justice in spite of his prepossessions. In the opposite camp Antonio Valbuena, a humorist of the mordant type, has still more difficulty in doing justice to any writer who is an academician, an American or a Liberal. Pascual de Gayangos y Arce and Manuel Milá y Fontanals escaped from the quarrels of contemporary schools by confining their studies to the past, and Marcelino Menéndez y Pelayo has earned a European reputation in the same province of historical criticism. Among his followers who have attained distinction it must suffice to mention Ramón Menéndez Pidal (b. 1869), author of *La Leyenda de los infantes de Lara* (1897), a brilliant piece of scientific, reconstructive criticism; Francisco Rodríguez Marín (b. 1855), who has published valuable studies on 16th and 17th century authors, and adds to his gifts as an investigator the charm of an alembicated, archaic style; Emilio Cotarelo y Mori (b. 1858), who, besides interesting contributions to the history of the theatre, has written substantial monographs on Enrique de Villena, Villamediana, Tirso de Molina, Iriarte and Ramón de la Cruz; and Adolfo Bonilla y San Martín (b. 1875), whose elaborate biography of Juan Luis Vives, which is a capital chapter on the history of Spanish humanism, gives him a foremost place among the scholars of the younger generation.

History and Criticism.

Bibliography.—The basis of study is Nicolás Antonio's *Bibliotheca hispana vetus* and *Bibliotheca hispana nova*, in the revised edition of Francisco Pérez Bayer (4 vols., Madrid, 1788). Supplementary to this are Bartolomé José Gallardo's *Ensayo de una biblioteca española de libros raros y curiosos* (4 vols., Madrid, 1863–1889), edited by M. R. Zarco del Valle and José Sancho Rayón; Pedro Salvá y Mallén's *Catálogo de la biblioteca de Salvá* (2 vols., Valencia, 1872); James Lyman Whitney's *Catalogue of the Spanish Library and of the Portuguese Books bequeathed by George Ticknor to the Boston Public Library* (Boston, 1879); Domingo Garcia Peres, *Catálogo de los autores portugueses que escribieron en castellano* (Madrid, 1890). For incunables the best authority is Conrádo Haebler, *Bibliografía ibérica del siglo xv.* (the Hague and Leipzig, 1904). Of general histories the most extensive is George Ticknor's *History of Spanish Literature* (3 vols., New York, 1849, and 6th ed., 3 vols., Boston, 1872), which is particularly valuable as regards bibliography; additional information is embodied in the German translation of this work by N. H. Julius (2 vols., Leipzig, 1852) and the supplement by F. J. Wolf (1867); and the Spanish translation by Pascual de Gayangos and Enrique de Vedia (4 vols., Madrid, 1851–1856) may be consulted with profit. On a smaller scale are G. Baist, *Die spanische Litteratur* (Strasburg, 1897) in the second volume of the *Grundriss der romanischen Philologie* (pt. ii.), H. Butler Clarke, *Spanish Literature* (London, 1893); Rudolph Beer, *Spanische Literaturgeschichte* (Leipzig, 1903); Philipp August Becker, *Geschichte der spanischen Literatur* (Strasburg, 1904). The three last-named include modern authors, as do E. Mérimée, *Précis d'histoire de la littérature espagnole* (Paris, 1908) and J. Fitzmaurice-Kelly, *History of Spanish Literature* (London, 1898; Spanish translation, Madrid, 1901, and French translation, with a revised text and serviceable bibliography). For the middle ages the best works are F. J. Wolf, *Studien zur Geschichte der spanischen und portugiesischen Nationalliteratur* (Berlin, 1859), and M. Milá y Fontanals, *De la Poesía heróico-popular castillana* (Barcelona, 1874). José Amador de los Ríos, *Historia crítica de la literatura española* (7 vols., Madrid, 1861–1865), is diffusive and inaccurate, but gives useful information concerning the period before the 16th century. On the drama the most solid works are Cayetano Alberto de la Barrera y Leirado, *Catálogo bibliográfico y biográfico del teatro antiguo español* (Madrid, 1860); A. Paz y Mélia, *Catálogo de las piezas de teatro que se conservan en el departamento de manuscritos de la biblioteca nacional* (Madrid, 1899); C. Pérez Pastor, *Nuevos dctos acerca del histrionismo español en los siglos xvi. y xvii.* (Madrid, 1901); José Sánchez-Arjona, *Noticias referentes á los anales del teatro en Sevilla* (Seville, 1898); Antonio Restori, "La Collezione della biblioteca palatina-parmense," in *Studj di filologia romanza*, fasc. 15 (Rome, 1891); E. Cotarelo y Mori, *Controversias sobre la licitud del teatro en España* (Madrid, 1904). Adolf Friedrich von Schack, *Geschichte der dramatischen Literatur und Kunst in Spanien* (Frankfort-on-Main, 1846–1854), a valuable work when published and still to be read with pleasure, is now out of date, and is not improved in the Spanish translation by Eduardo de Mier; it is in course of being superseded by Wilhelm Creizenach's *Geschichte des neueren Dramas*, of which three volumes have already appeared (Halle, 1893–1903). Two fluent and agreeable works on the subject are Adolf Schaeffer, *Geschichte des spanischen Nationaldramas* (2 vols., Leipzig, 1890), and Louis de Viel Castel, *Essai sur le théâtre espagnol* (2 vols., Paris, 1882). Julius Leopold Klein's extravagant prejudices detract greatly from the value of *Das spanische Drama* (Leipzig, 1871–1875), which forms part of his *Geschichte des Dramas*; but his acumen and learning are by no means contemptible. Other works on the Spanish drama are indicated by A. Morel-Fatio and L. Rouanet in their critical bibliography, *Le Théâtre espagnol* (Paris, 1900). The prefaces by M. Menéndez y Pelayo in the *Antología de poetas líricos castellanos desde la formación del idioma hasta nuestros días* (12 vols. already published, Madrid, 1890–1906) form a substantial history of Spanish poetry. The same writer's *Orígenes de la novela* (Madrid, 1905–1907) and unfinished *Historia crítica de las ideas estéticas en España* (9 vols., Madrid, 1884–1891), are highly instructive. For the 18th century the student is referred to the *Historia crítica de la poesía castellana en el siglo xviii.* (3rd ed., 3 vols., Madrid, 1893) by Leopoldo Augusto de Cueto, marqués de Valmar; Francisco Blanco García, *La Literatura española en el siglo xix.* (3 vols., Madrid, 1891–1894), is useful and informing, but must be consulted with caution, owing to the writer's party spirit. Similar prejudices are present in the much more suggestive and acute volumes of Leopoldo Alas. The history of modern criticism is traced by Francisco Fernández y González, *Historia de la crítica literaria en España desde Luzán hasta nuestros días* (Madrid, 1870). Among miscellaneous monographs and essays the most recommendable are Count Théodore de Puymaigre, *Les vieux auteurs castillans* (Paris 1861–1862; 2nd ed., incomplete, 2 vols., Paris, 1889–1890), and *La Cour littéraire de don Juan II. roi de Castille* (2 vols., Paris, 1893); A. Morel-Fatio, *L'Espagne au xvi^{me} et au xvii^{me} siècle* (Heilbronn, 1878), and *Etudes sur l'Espagne* (3 vols., Paris, 1888–1904); Enrique Piñeyro, *El Romanticismo en España* (Paris, 1904); J. Fitzmaurice-Kelly, *Chapters on Spanish Literature* (London, 1908). The *Revue hispanique* (Paris) and the *Bulletin hispanique* (Bordeaux) are specially dedicated to studies on the literary history of Spain, and articles on the subject appear from time to time in

Romania, the *Zeitschrift für romanische Philologie* and *Romanische Forschungen*, as also in *Modern Language Notes* (Baltimore) and the *Modern Language Review* (Cambridge).

2. *Catalan Literature*.—Although the Catalan language is simply a branch of the southern Gallo-Roman, the literature, in its origin at least, should be considered as supplementary to that of Provence. Indeed, until about the second half of the 13th century there existed in the Catalan districts no other literature than the Provençal, and the poets of north-eastern Spain used no other language than that of the troubadours. Guillem de Bergadan, Uc de Mataplana, Ramón Vidal de Besalú, Guillem de Cervera, Serveri de Gerona and other verse writers of still more recent date were all genuine Provençal poets, in the same sense as are those of Limousin, Quercy or Auvergne, since they wrote in the *langue d'oc* and made use of all the forms of poetry cultivated by the troubadours north of the Pyrenees. Ramón Vidal (end of the 12th century and beginning of 13th) was a grammarian as well as a poet; his *Rasos de trobar* became the code for the Catalan poetry written in Provençal, which he called *Lemosi*, a name still kept up in Spain to designate, not the literary idiom of the troubadours only, but also the local idiom—Catalan—which the Spaniards chose to consider as derived from the former. The influence of R. Vidal and other grammarians of his school, as well as that of the troubadours we have named, was enduring; and even after Catalan prose—an exact reflection of the spoken language of the south-east of the Pyrenees—had given evidence of its vitality in some considerable works, Catalan poetry remained faithful to the Provençal tradition. From the combination of spoken Catalan with the literary language of the troubadours there arose a sort of composite idiom, which has some analogy with the Franco-Italian current in certain parts of Italy in the middle ages, although in the one case the elements of the mixture are more distinctly apparent than are the romance of France and the romance of Italy in the other. The poetical works of Raymond Lully or Ramón Lull are among the oldest examples of this Provençalised Catalan; one has only to read the fine piece entitled *Lo Desconort* ("Despair"), or some of his stanzas on religious subjects, to apprehend at once the eminently composite nature of that language. Muntaner in like manner, whose prose is exactly that spoken by his contemporaries, becomes a troubadour when he writes in verse; his *Sermó* on the conquest of Sardinia and Corsica (1323), introduced into his *Chronicle* of the kings of Aragon, exhibits linguistically the same mixed character as is found in Lully, or, we may venture to say, in all Catalan verse writers of the 14th century. These are not very numerous, nor are their works of any great merit. The majority of their compositions consist of what were called *noves rimades*, that is, stories in octosyllabic verse in rhymed couplets. There exist poems of this class by Pere March, by a certain Torrella, by Bernat Metge (an author more celebrated for his prose), and by others whose names we do not know; among the works belonging to this last category special mention ought to be made of a version of the romance of the *Seven Sages*, a translation of a book on good breeding entitled *Facetus*, and certain tales where, by the choice of subjects, by various borrowings, and even occasionally by the wholesale introduction of pieces of French poetry, it is clearly evident that the writers of Catalonia understood and read the *langue d'oui*. Closely allied to the *noves rimades* is another analogous form of versification—that of the *codolada*, consisting of a series of verses of eight and four syllables, rhyming in pairs, still made use of in one portion of the Catalan domain (Majorca).

Poetry of Middle Ages.

The 15th century is the golden age of Catalan poetry. At the instigation and under the auspices of John I. (1387–1395), Martin I. (1395–1410), and Ferdinand I. (1410–1416), kings of Aragon, there was founded at Barcelona a consistory of the "Gay Saber," on the model of that of Toulouse, and this official protection accorded to poetry was the beginning of a new style much more emancipated from Provençal influence. It cannot be denied, indeed, that its forms are of foreign importation, that the Catalan verse writers accept the prescriptions of the *Leys d'amor* of Guillaume Molinier, and that the names which they gave to their *cobles* (stanzas) are all borrowed from the same *art de trobar* of the Toulouse school; but their language begins to rid itself more and more of Provençalisms and tends to become the same as that of prose and of ordinary conversation. With Pere and Jaume March, Jordi de Sant Jordi, Johan de Masdovelles, Francesch Ferrer, Pere Torroella, Pau de Bellviure, Antoni Vallmanya, and, above all, the Valencian Auzias March, there developed a new school, which flourished till the end of the 15th century, and which, as regards the form of its versification, is distinguished by its almost exclusive employment of eight-verse *cobles* of ten syllables, each with "crossed" or "chained" rhymes (*cobla crohada* or *encadenada*), each composition ending with a *tornada* of four verses, in the first of which the "device" (*divis* or *senyal*) of the poet is given out. Many of these poems are still unedited or have only recently been extracted from the *cançoners*, where they had been collected in the 15th century. Auzias March alone, the most inspired, the most profound, but also the most obscure of the whole group, was printed in the 16th century; his *cants d'amor and cants de mort* contain the finest verses ever written in Catalan, but the poet fails to keep up to his own high level, and by his studied obscurity occasionally becomes unintelligible to such a degree that one of his editors accuses him of having written in Basque. Of a wholly different class, and in quite another spirit, is the *Libre de les dones* of Jaume Roig (d. 1478), a Valencian also, like March; this long poem is a *nova rimada*, only *comediada*, that is to say, it is in quadrisyllabic instead of octosyllabic verse. A bitter and caustic satire upon women, it purports to be a true history—the history of the poet himself and of his three unhappy marriages in particular. Notwithstanding its author's allegations, however, the *Libre de les dones* is mostly fiction; but it derives a very piquant interest from its really authentic element, its vivid picture of the Valencia of the 15th century and the details of contemporary manners. After this bright period of efflorescence Catalan poetry rapidly faded, a decline due more to the force of circumstances than to any fault of the poets. The union of Aragon with Castile, and the resulting predominance of Castilian throughout Spain, inflicted a death-blow on Catalan literature, especially on its artistic poetry, a kind of composition more ready than any other to avail itself of the triumphant idiom which soon came to be regarded by men of letters as the only noble one, and alone fit to be the vehicle of elevated or refined thoughts. The fact that a Catalan, Juan Boscan, inaugurates in the Castilian language a new kind of poetry, and that the Castilians themselves regard him as the head of a school, is important and characteristic; the date of the publication of the works of Boscan (1543) marks the end of Catalan poetry.

15th Century.

The earliest prose works in Catalan are later than the poems of the oldest Catalan troubadours of the Provençal school; these prose writings date no further back than the close of the 13th century, but they have the advantage of being entirely original. Their language is the very language of the soil which we see appearing in charters from about the time of the accession of James I. (1213). This is true especially of the chronicles, a little less so of the other writings, which, like the poetry, do not escape the influence of the more polished dialect of the country to the north of the Pyrenees. Its chronicles are the best ornament of medieval Catalan prose. Four of them—that of James I., apparently reduced to writing a little after his death (1276) with the help of memoirs dictated by himself during his lifetime; that of Bernat Desclot, which deals chiefly with the reign of Pedro III. of Aragon (1276–1286); that of Ramon Muntaner (first half of the 14th century), relating at length the expedition of the Catalan company to the Morea and the conquest of Sardinia by James II.; finally that of Pedro IV., the Ceremonious (1335–1387), genuine commentaries of that astute monarch, arranged by certain officials of his court, notably by Bernat Descoll—these four works are distinguished alike by the artistic skill of their

Prose of 13th–15th Centuries.

narration and by the quality of their language; it would not be too much to liken these Catalan chroniclers, and Muntaner especially, to Villehardouin, Joinville and Froissart. The Doctor Illuminatus, Raymond Lully, whose acquaintance with Latin was very poor—his philosophical works were done into that language by his disciples—wrote in a somewhat Provençalized Catalan various moral and propagandist works—the romance *Blanquerna* in praise of the solitary life, the *Libre de les maravelles,* into which is introduced a "bestiary" taken by the author from *Kalilah and Dimnah*, and the *Libre del orde de cavalleria*, a manual of the perfect knight, besides a variety of other treatises and opuscula of minor importance. The majority of the writings of Lully exist in two versions—one in the vernacular, which is his own, the other in Latin, originating with his disciples, who desired to give currency throughout Christendom to their master's teachings. Lully—who was very popular in the lay world, although the clergy had a low opinion of him and in the 15th century even set themselves to obtain a condemnation of his works by the Inquisition—had a rival in the person of Francesch Ximenez or Eximeniz, a Franciscan, born at Gerona some time after 1350. His *Crestiá* (printed in 1483) is a vast encyclopaedia of theology, morals and politics for the use of the laity, supplemented in various aspects by his three other works—*Vida de Jesucrist*, *Libre del angels*, and *Libre de les dones*; the last named, which is at once a book of devotion and a manual of domestic economy, contains a number of curious details as to a Catalan woman's manner of life and the luxury of the period. Lully and Eximeniz are the only Catalan authors of the 14th century whose works written in a vulgar tongue had the honour of being translated into French shortly after their appearance.

We have chiefly translators and historians in the 15th century. Antoni Canals, a Dominican, who belongs also to the previous century, translates into Catalan Valerius Maximus and a treatise of St Bernard; Bernat Metge, himself well versed in Italian literature, presents some of its great masters to his countrymen by translating the *Griselidis* of Petrarch, and also by composing *Lo Sompni* ("The Dream"), in which the influence of Dante, of Boccaccio, and, generally speaking, of the Italy of the 13th and 14th centuries is very perceptible. The *Feyts d'armes de Catalunya* of Bernat Boades (d. 1444), a knightly chronicle brought to a close in 1420, reveals a spirit of research and a conscientiousness in the selection of materials which are truly remarkable for the age in which it was written. On the other hand, Pere Tomich, in his *Histories é conquestes del reyalme d'Aragó* (1448), carries us back too much to the manner of the medieval chroniclers; his credulity knows no bounds, while his style has altogether lost the naïve charm of that of Muntaner. To the list of authors who represent the leading tendencies of the literature of the 15th century we must add the name of Johanot Martorell, a Valencian author of three-fourths of the celebrated romance, *Tirant lo blanch* (finished in 1460 and printed in 1490), which the reader has nowadays some difficulty in regarding as that "treasury of content" which Cervantes will have it to be.

16th-18th Centuries.

With the loss of political was bound to coincide that of literary independence in the Catalonian countries. Catalan fell to the rank of a patois and was written less and less; lettered persons ceased to cultivate it, and the upper classes, especially in Valencia, owing to the proximity of Castile, soon affected to make no further use of the local speech except in familiar conversation. The 16th century, in fact, furnishes literary history with hardly more than a single poet at all worthy of the name—Pere Serafí, some of whose pieces, in the style of Auzias March, but less obscure, are graceful enough and deserve to live; his poems were printed at Barcelona in 1565. Prose is somewhat better represented, but scholars alone persisted in writing in Catalan—antiquaries and historians like Miquel Carbonell (d. 1517), compiler of the *Chroniques de Espanya* (printed in 1547), Francesch Tarafa, author of the *Cronica de cavallers catalans*, Anton Beuter and some others not so well known In the 17th and 18th centuries the decadence became still more marked. A few scattered attempts to restore to Catalan, now more and more neglected by men of letters, some of its old life and brilliance failed miserably. Neither Hieronim Pujades, author of an unfinished *Coronica universal del principat de Catalunya* (Barcelona, 1609), nor even Vicent Garcia, rector of Vallfogona (1582–1623), a verse-writer by no means destitute of verve or humour, whose works were published in 1700 under the quaint title of *La Armonia del Parnás, mes numerosa en las poesias varias del atlant del cel poetic lo Dr Vicent Garcia*, and whose literary talent and originality have been greatly exaggerated by the Catalans of the present day, could induce his countrymen to cultivate the local idiom once more. Sermons, lives of saints, a few works of devotion, didactic treatises and the like are all that was written henceforth in Catalan till the beginning of the 19th century. Writers who were Catalan by birth had so completely unlearned their mother-tongue that it would have seemed to them quite inappropriate, and even ridiculous, to make use of it in serious works, so profoundly had Castilian struck its roots in the eastern provinces of Spain, and so thoroughly had the work of assimilation been carried out to the advantage of the official language of the court and of the government.

Revival of Catalan Language and Literature.

In 1814 appeared the *Gramática y apologia de la llengua Cathalana* of Joseph Pau Ballot y Torres, which may be considered as marking the origin of a genuine renaissance of the grammatical and literary study of Catalan. Although the author avows no object beyond the purely practical one of giving to strangers visiting Barcelona for commercial purposes some knowledge of the language, the enthusiasm with which he sings the praises of his mother-tongue, and his appended catalogue of works which have appeared in it since the time of James I., show that this was not his only aim. In point of fact the book, which is entitled to high consideration as being the first systematic Catalan grammar, written, too, in the despised idiom itself, had a great influence on the authors and literary men of the principality. Under the influence of the new doctrines of romanticism twenty years had not passed before a number of attempts in the way of restoring the old language had made their appearance, in the shape of various poetical works of very unequal merit. The *Oda á la patria* (1833) of Buenaventura Carlos Aribau is among the earliest if not actually the very first of these, and it is also one of the best; the modern Catalan school has produced few poems more inspired or more correct. Following in the steps of Aribau, Joaquin Rubio y Ors (*Lo Gayter del Llobregat*), Antonio de Bofarull (*Lo Coblejador de Moncada*), and soon afterwards a number of other versifiers took up the lyre which it might have been feared was never to sound again since it fell into the hands of Auzias March. The movement spread from Catalonia into other provinces of the ancient kingdom of Aragon; the appeal of the Catalans of the principality was responded to at Valencia and in the Balearic Isles. Later, the example of Provence, of the *felibritge* of the south of France, accelerated still further this renaissance movement, which received official recognition in 1859 by the creation of the *jochs florals*, in which prizes are given to the best competitors in poetry, of whom some succeed in obtaining the diploma of *mestre en gay saber*. It is of course impossible to foresee the future of this new Catalan literature—whether it is indeed destined for that brilliant career which the Catalans themselves anticipate. In spite of the unquestionable talent of poets like Mariano Aguiló (Majorca), Teodoro Llorente (b. 1836; Valencia), and more especially Jacinto Verdaguer (1845–1902), author of an epic poem *Atlántida* and of the very fascinating *Cants mistichs*, it is by no means certain that this renaissance of a provincial literature will be permanent now that the general tendency throughout Europe is towards unity and centralization in the matter of language. At all events it would be well if the language were somewhat more fixed, and if its writers no longer hesitated between a pretentious archaism and the incorrectness of vulgar colloquialism. Some improvement in this respect is discernible in the poems of Joan Maragall (b. 1860), the lyrical verse of

Apeles Mestre (b. 1854), the fiction of Narcis Oller and Santiago Rusiñol, as also in the dramas of Angel Guimerá, and if the process be continued there may be a future, as well as a past, for Catalan literature.

(J. F.-K.; A. M.-Fa.)

SPALATIN, GEORGE, the name taken by George Burkhardt (1484–1545), an important figure in the history of the Reformation, who was born on the 17th of January 1484, at Spalt (whence he assumed the name Spalatinus), near Nuremberg, where his father was a tanner. He went to Nuremberg for his education when he was thirteen years of age, and soon afterwards to the university of Erfurt, where he took his bachelor's degree in 1499. There he attracted the notice of Nikolaus Marschalk, the most influential professor, who made Spalatin his amanuensis and took him to the new university of Wittenberg in 1502. In 1505 Spalatin returned to Erfurt to study jurisprudence, was recommended to Conrad Mutianus, and was welcomed by the little band of German humanists of whom Mutianus was chief. His friend got him a post as teacher in the monastery at Georgenthal, and in 1508 he was ordained priest by Bishop Johann von Laasphe, who had ordained Luther. In 1509 Mutianus recommended him to Frederick III. the Wise, the elector of Saxony, who employed him to act as tutor to his nephew, the future elector, John Frederick. Spalatin speedily gained the confidence of the elector, who sent him to Wittenberg in 1511 to act as tutor to his nephews, and procured for him a canon's stall in Altenburg. In 1512 the elector made him his librarian. He was promoted to be court chaplain and secretary, and took charge of all the elector's private and public correspondence. His solid scholarship, and especially his unusual mastery of Greek, made him indispensable to the Saxon court.

Spalatin had never cared for theology, and, although a priest and a preacher, had been a mere humanist. How he first became acquainted with Luther it is impossible to say—probably at Wittenberg; but the reformer from the first exercised a great power over him, and became his chief counsellor in all moral and religious matters. His letters to Luther have been lost, but Luther's answers remain, and are extremely interesting. There is scarcely any fact in the opening history of the Reformation which is not connected in some way with Spalatin's name. He read Luther's writings to the elector, and translated for his benefit those in Latin into German. He accompanied Frederick to the Diet of Augsburg in 1518, and shared in the negotiations with the papal legates, Cardinal Cajetan and Karl von Miltitz. He was with the elector when Charles was chosen emperor and when he was crowned. He was with his master at the Diet of Worms. In short, he stood beside Frederick as his confidential adviser in all the troubled diplomacy of the earlier years of the Reformation. Spalatin would have dissuaded Luther again and again from publishing books or engaging in overt acts against the Papacy, but when the thing was done none was so ready to translate the book or to justify the act.

On the death of Frederick the Wise in 1525 Spalatin no longer lived at the Saxon court. But he attended the imperial diets, and was the constant and valued adviser of the electors, John and John Frederick. He went into residence as canon at Altenburg, and incited the chapter to institute reforms somewhat unsuccessfully. He married in the same year. During the later portion of his life, from 1526 onwards, he was chiefly engaged in the visitation of churches and schools in electoral Saxony, reporting on the confiscation and application of ecclesiastical revenues, and he was asked to undertake the same work for Albertine Saxony. He was also permanent visitor of Wittenberg University. Shortly before his death he fell into a state of profound melancholy, and died on the 16th of January 1545, at Altenburg.

Spalatin left behind him a large number of literary remains, both published and unpublished. His original writings are almost all historical. Perhaps the most important of them are: *Annales reformationis*, edited by E. S. Cyprian (Leipzig, 1718); and "Das Leben und die Zeitgeschichte Friedrichs des Weisen," published in *Georg Spalatins Historischer Nachlass und Briefe*, edited by C. G. Neudecker and L. Preller (Jena, 1851). A list of them may be found in A. Seelheim's *George Spalatin als sächs. Historiographer* (1876). There is no good life of Spalatin, nor can there be until his letters have been collected and edited, a work still to be done. There is an excellent article on Spalatin, however, by T. Kolde, in Herzog-Hauck, *Realencyklopädie*, Bd. xviii. (1906).

SPALATO, or Spalatro (Serbo-Croatian *Spljet* or *Split*), an episcopal city, and the centre of an administrative district, in Dalmatia, Austria, and on the Adriatic Sea. Pop. (1900), of town and commune, 27,198; chiefly Serbo-Croatian, and almost exclusively Roman Catholic. Spalato is situated on the seaward side of a peninsula between the Gulf of Brazza and the Gulf of Salona. Though not the capital, it is commercially the most important city in Dalmatia and carries on an extensive trade in wine and oil. It is a port of call for the Austrian Lloyd steamers, and communicates by rail with Sebenico, Knin and Sinj. Spalato has a striking sea-front, in which the leading feature is the ruined façade of the great palace of Diocletian, to which the city owes its origin. A large part of Spalato is actually within the limit of the palace; and many modern houses are built against its ancient walls and incorporate parts of them, not only on the inner but also on the outer side. This palace was erected between A.D. 290 and 310. In ground plan it is almost a square, with a quadrangular tower at each of the four corners. It covers $9\frac{1}{2}$ acres. There were originally four principal gates, with four streets meeting in the middle of the quadrangle, after the style of a Roman camp. The eastern gate, or Porta Aenea, is destroyed, but, though the side towers are gone, the western gate, or Porta Ferrea, and the main entrance of the building, the beautiful Porta Aurea, in the north front, are still in fairly good preservation. The streets are lined with massive arcades. The vestibule now forms the Piazza del Duomo or cathedral square; to the north-east of this lies the temple of Jupiter, or perhaps the mausoleum. This has long been the cathedral of St Doimo or Domnius, small and dark, but noteworthy for its finely carved choir stalls. To the south-east is the temple of Aesculapius, which served originally as a kind of court chapel, and has long been transformed into a baptistery. A beautiful Romanesque campanile was added to the baptistery in the 14th and 15th centuries. Architecturally the most important of the many striking features of the palace is the arrangement in the vestibule by which the supporting arches spring directly from the capitals of the large granite Corinthian columns. This, as far as the known remains of ancient art are concerned, is the first instance of such a method.

The ruins of Salona or Salonae, lying about 4 m. north-east of the palace, were chiefly exhumed during a series of excavations undertaken after the visit of the emperor Francis I. in 1818. Research was carried on regularly from 1821 to 1827, and again from 1842 to 1850. It was afterwards resumed at intervals until 1877, when the excavation committee was granted an annual subsidy by the Austrian government. Many discoveries were made, including the ruins of a theatre, amphitheatre, city walls and gates, baths, aqueducts, pagan and Christian cemeteries, basilicas and many fragments of houses and arches. Professor F. Bulić, who had charge of the work and of the museum at Spalato, reported in 1894 that the collection of minor objects comprised "2034 inscriptions, 387 sculptures, 176 architectural pieces, 1548 fragments or objects of terra-cotta and vases, 1243 objects of glass, 3184 of metal, 929 of bone, 1229 gems, 128 objects from prehistoric times, and 15,000 coins" (Munro, p. 244). These are preserved in the museum. One vase, of Corinthian workmanship, dates from the 6th century B.C.; and many of the early Christian relics are of unusual interest. The so-called "cyclopean" walls, mortarless, but constructed of neatly squared and fitted blocks, are probably of Roman workmanship. Jackson suggests that perhaps, like the long walls at Athens, they were intended to unite the city with its port.

Salona under the early Roman emperors was one of the chief ports of the Adriatic, on one of the most central sites in the Roman world. Made a Roman colony after its second capture by the Romans (78 B.C.), it appears as *Colonia Martia Julia* and *Colonia Claudia Augusta Pia Veteranorum*, and bears at different periods the titles of *respublica*, *conventus*, *metropolis*, *praefectura* and *praetorium*. Diocletian died in 313; and before long the city became an episcopal see, with St Doimo as its first bishop. The palace was transformed into an imperial cloth factory, and, as most of the workers were women, it became known as the *gynaecium*. Salona was several times taken and retaken by the Goths and Huns before 639, when it was sacked and nearly destroyed by the Avars. Its inhabitants fled to the Dalmatian islands, but returned shortly afterwards to found a new city within the walls of the palace. Salona itself was not entirely deserted until the close of the 12th century. In 650 the papal legate, John of Ravenna, was created bishop of Spalato, as the new city was named. "Spalato," or "Spalatro" (a very old spelling), was long regarded as a corruption of *Salonae Palatium*; but its true origin is doubtful. The most ancient form is *Aspalathum*, used in the 10th century by Constantine Porphyrogenitus. *Spalathum*, *Spalathrum* and *Spalatrum* are early variants. In a few years Spalato became an archbishopric, and its holders were metropolitans of all Dalmatia until 1033. In 1105 Spalato became a vassal state of Hungary; in 1327 it revolted to Venice; in 1357 it returned to its allegiance. It was ruled by the Bosnian king, Tvrtko, from 1390 to 1391; and in 1402 the famous and powerful Bosnian prince, Hrvoje or Harvoye, received the dukedom of Spalato from Ladislaus of Naples, the claimant to the Hungarian throne. In 1413, after the overthrow of Ladislaus by the emperor Sigismund, Hrvoje was banished; but a large octagonal tower, the Torre d'Harvoye, still bears his name. Spalato received a Venetian garrison in 1420, and ceased to have an independent history. The castle and city walls, erected by the Venetians between 1645 and 1670. were dismantled after 1807.

See T. G. Jackson, *Dalmatia, the Quarnero and Istria* (Oxford, 1887); and E. A. Freeman, *Subject and Neighbour Lands of Venice* (London, 1881), for a general description of Spalato, its antiquities and history. A valuable account of the researches at Salona is given in R. Munro, *Bosnia-Herzegovina and Dalmatia* (London, 1900). There are two magnificently illustrated volumes which deal with Diocletian's palace: R. Adam, *Ruins of the Palace of the Emperor Diocletian at Spalatro, in Dalmatia* (London, 1764), engravings by Bartolozzi; and L. J. Cassas and J. Lavallée, *Voyage pittoresque et historique de l'Istrie* (Paris, 1802). The Dalmatian chronicles, reproduced by G. Lucio in his *De regno Dalmatiae et Croatiae* (Amsterdam, 1666), include several which deal specially with Salona and Spalato. The most important is the *Historia salonitanorum pontificum et spalatensium*, by Thomas, archdeacon of Spalato (1200–1268).

SPALDING, WILLIAM (1809–1859), British author, was born in Aberdeen on the 22nd of May 1809. He was educated at the grammar school there and at Marischal College, and he went in 1830 to Edinburgh, where he was called to the bar in 1833. In that year he published a *Letter on Shakespeare's Authorship of the two Noble Kinsmen* (reprinted for the New Shakspere Society in 1876), which attracted the notice of Jeffrey, who invited Spalding to contribute to the *Edinburgh Review*. He also spent some time in Italy, and in 1841 published *Italy and the Italian Islands from the Earliest Ages to the Present Time*. He occupied the chair of rhetoric in Edinburgh University from 1840 to 1845, when he was appointed professor of logic in the university of St Andrews, a post which he held till his death on the 16th of November 1859.

Besides contributions to the *Edinburgh Review*, *Blackwood's Magazine* and the eighth edition of the *Encyclopaedia Britannica*, he was the author of a concise *History of English Literature* (1853).

SPALDING, a market town in the Holland or Spalding parliamentary division of Lincolnshire, England, on the river Welland, and on the Great Northern and Great Eastern railways, 93 m. N. from London. Pop. of urban district (1901), 9385. The town is the centre of a rich agricultural district. The parish church of St Mary and St Nicholas was built in 1284 and is of peculiar construction, having four aisles to the nave. It is mainly Decorated in style. The adjoining lady chapel (St Mary and St Thomas à Becket) was built in 1315; in 1588 it was appropriated for the grammar school endowed in 1568 by John Blanke and again in 1588 by John Gamlyn. A new grammar school was erected in 1881. There are several modern churches and chapels, a corn exchange, a Christian association and literary institute, and the Johnson hospital (1881, endowed). The existing high bridge over the Welland, constructed in 1838, took the place of a wooden erection dating from the end of the 17th century; this last was built on the site of a Roman bridge of two arches, the foundations of the centre pier of which were disclosed when the wooden bridge was constructed. Trade is principally agricultural, and there is considerable water-traffic on the Welland.

Although there are no traces of settlement at Spalding (*Spaltnige*) before late Saxon times there was probably a village here before Thorold the sheriff founded his cell of Crowland Abbey in 1051. In Domesday Book the manor is said to belong to Ivo de Taillebois, who possessed a market there worth 40s., six fisheries and rent from salt-pans. The manor was afterwards granted to Angers, and later belonged to Spalding Priory, which retained it until at the suppression it passed to the Crown. Stephen made Spalding Priory free of toll, while John gave the monks forest rights. The town was governed by the prior's manorial court, and never became a parliamentary or municipal borough. The prior obtained the grant of the Friday market in 1242, and in the reign of Edward I. claimed from of old fairs on the feast of St Nicholas and fifteen days following, and on the vigil and octave of St Cross. In more modern times Spalding was well known for the club known as the "Gentleman's Society," founded in 1710 by Maurice Johnson, which met once a week at a coffee-house in the town for the discussion of literary and antiquarian subjects, and numbered among its members Newton, Bentley, Addison, Pope and Gay.

SPALLANZANI, LAZARO (1729–1799), Italian man of science, was born at Scandiano in Modena on the 10th of January 1729, and was at first educated by his father, who was an advocate. At the age of fifteen he was sent to the Jesuit college at Reggio di Modena, and was pressed to enter that body. He went, however, to the university of Bologna, where his famous kinswoman, Laura Bassi, was professor of physics, and it is to her influence that his scientific impulse has been usually attributed. With her he studied natural philosophy and mathematics, and gave also great attention to languages, both ancient and modern, but soon abandoned the study of law, and afterwards took orders. His reputation soon widened, and in 1754 he became professor of logic, metaphysics and Greek in the university of Reggio, and in 1760 was translated to Modena, where he continued to teach with great assiduity and success, but devoted his whole leisure to natural science. He declined many offers from other Italian universities and from St Petersburg until 1768, when he accepted the invitation of Maria Theresa to the chair of natural history in the university of Pavia, which was then being reorganized. He also became director of the museum, which he greatly enriched by the collections of his many journeys along the shores of the Mediterranean. In 1785 he was invited to Padua, but to retain his services his sovereign doubled his salary and allowed him leave of absence for a visit to Turkey, where he remained nearly a year, and made many observations, among which may be noted those of a copper mine in Chalki and of an iron mine at Principi. His return home was almost a triumphal progress: at Vienna he was cordially received by Joseph II., and on reaching Pavia he was met with acclamations outside the city gates by the students of the university. During the following year his students exceeded five hundred. His integrity in the management of the museum was called in question, but a judicial investigation speedily cleared his honour, to the satisfaction even of his accusers. In 1788 he visited Vesuvius and the volcanoes of the Lipari Islands and Sicily, and embodied the results of his researches in a large work (*Viaggi alle due Sicilie ed in alcune parti dell' Apennino*), published four years later. He died from an apoplectic seizure on the 12th of February 1799, at Pavia.

His indefatigable exertions as a traveller, his skill and good fortune as a collector, his brilliance as a teacher and expositor, and his keenness as a controversialist no doubt aid largely in accounting for Spallanzani's exceptional fame among his contemporaries; yet greater qualities were by no means lacking. His life was one of incessant eager questioning of nature on all sides, and his many and varied works all bear the stamp of a fresh and original genius, capable of stating and solving problems in all departments of science—at one time finding the true explanation of "ducks and drakes" (formerly attributed to the elasticity of water) and at another helping to lay the foundations of our modern vulcanology and meteorology. His main discoveries, however, were in the field of physiology: he wrote valuable and suggestive papers on respiration, on the senses of bats, &c., while he made experiments (1768) to disprove the occurrence of spontaneous generation, showing in opposition to J. H. Needham (1713–1781) that animalcules did not develop in vegetable infusions which had been boiled and were kept in properly closed vessels. His great work, however, is the *Dissertationi de fisica animale e vegetale* (2 vols., 1780). Here he first interpreted the process of digestion, which he proved to be no mere mechanical process of trituration, but one of actual solution, taking place primarily in the stomach, by the action of the gastric juice. He also carried out important researches on fertilization in animals (1780).

SPAN (from O. Eng. *spannan*, to bind, connect together; the word is of general occurrence in Teutonic languages, the ultimate origin being the root *spa-*, to extend, stretch out, cf. Gr. *σπᾶν*, to draw out, Lat. *spatium*, space), a distance stretched, the space between terminal points. The word was formerly used as a measure of length = 10·368 in., taken from the stretch of the fully opened hand from thumb to little finger. The term is used in architecture for the width or opening of an arch or arched opening, and also the width of a roof between the wall plates. A "span roof" is a roof having two sides inclining to a centre or ridge, in contradistinction to a "shed roof" (see SHED).

SPANDAU, a town of Germany, in the Prussian province of Brandenburg, at the confluence of the Havel and Spree, 8 m. N.W. of Berlin, of which it is practically a suburb, on the main lines of railway to Hanover and Hamburg respectively. Pop. (1885), 31,463; (1895), 55,813; (1905), 70,295 (including a garrison of about 5000). The town has of recent years made marked progress, its trade being enhanced by an excellent railway service with Berlin and improved navigation on the Havel. The fortifications, which were strengthened after the war, 1870–71, for the protection of the arsenal, have been razed on the northern and eastern sides, and of its former defences none remain except the citadel and a line of works along a ridge of hills to the south of the town. The Julius tower in the citadel, which is surrounded by water, contains the Imperial war treasure (*Reichskriegsschatz*),—a sum of £6,000,000 in gold, kept in readiness for any warlike emergency, and reserved from the indemnity paid by France after the war of 1870–71. Spandau contains four Protestant churches, a Roman Catholic church, a gymnasium and a school of musketry. Besides numerous barracks, there are various military establishments appropriate to an important garrison town; and its chief industries are connected with the preparation of munitions of war. The government factories for the manufacture of small arms, artillery, gunpowder, &c., cover upwards of 200 acres, and employ about 6000 workmen. The other industries are not very important; they comprise miscellaneous manufactures, fishing, boat-building, and some shipping on the Havel.

Spandau is one of the oldest places in the Altmark, and received civic rights in 1232. It afterwards became a favourite residence of the Hohenzollern electors of Brandenburg, and was fortified in 1577–1583. In 1635 it surrendered to the Swedes, and in 1806 to the French. A short investment in 1813 restored it to Prussia.

See Zech and Günther, *Geschichtliche Beschreibung der Stadt und Festung Spandau* (Spandau, 1847), and Kuntzemüller, *Urkundliche Geschichte der Stadt und Festung Spandau* (Spandau, 1881).

SPANDRIL, or SPANDREL (formerly *splaundrel*, a word of unknown origin), in architecture, the space between any arch or curved brace and the level label, beams, &c., over the same. The spandrils over doorways in Perpendicular work are generally richly decorated. At Magdalen College, Oxford, is one which is perforated, and has a most beautiful effect. The spandril of doors is sometimes ornamented in the Decorated period, but seldom forms part of the composition of the doorway itself, being generally over the label.

SPANGENBERG, AUGUST GOTTLIEB (1704–1792), Count Zinzendorf's successor, and bishop of the Moravian Brethren, was born on the 15th of July 1704 at Klettenberg, on the south of the Harz Mountains, where his father, Georg Spangenberg, was court preacher and ecclesiastical inspector of the countship of Hohenstein. Left an orphan at the early age of thirteen, he was sent to the gymnasium at Ilefeld, and passed thence (1722), in poorest circumstances, to the university of Jena to study law. Professor Johann Franz Buddeus (1667–1729) received him into his family, and a "stipendium" was procured for him. He soon abandoned law for theology: took his degree in 1726, and began to give free lectures on theology. He also took an active part in a religious union of students, in the support of the free schools for poor children established by them in the suburbs of Jena, and in the training of teachers. In 1728 Count Zinzendorf visited Jena, and Spangenberg made his acquaintance; in 1730 he visited the Moravian colony at Herrnhut. A "collegium pastorale practicum" for the care of the sick and poor was in consequence founded by him at Jena, which the authorities at once broke up as a "Zinzendorfian institution." But Spangenberg's relations with the Moravians were confirmed by several visits to the colony, and the accident of an unfavourable appeal to the lot alone prevented his appointment as chief elder of the community, March 1733. Meanwhile his free lectures in Jena met with much acceptance, and led to an invitation from Gotthilf Francke to the post of assistant professor of theology and superintendent of schools connected with his orphanage at Halle. He accepted the invitation, and entered on his duties in September 1732. But differences between the Pietists of Halle and himself soon became apparent. He found their religious life too formal, external and worldly; and they could not sanction his comparative indifference to doctrinal correctness and his incurable tendency to separatism in church life. Spangenberg's participation in private observances of the Lord's Supper and his intimate connexion with Count Zinzendorf brought matters to a crisis. He was offered by the senate of the theological faculty of Halle the alternative of doing penance before God, submitting to his superiors, and separating himself from Zinzendorf, or leaving the matter to the decision of the king, unless he preferred to "leave Halle quietly." The case came before the king, and, on the 8th of April 1733, Spangenberg was conducted by the military outside the gates of Halle. At first he went to Jena, but Zinzendorf at once sought to secure him as a fellow labourer, though the count wished to obtain from him a declaration which would remove from the Pietists of Halle all blame with regard to the disruption. Spangenberg went to Herrnhut and found amongst the Moravians his life-work, having joined them at a moment when the stability of the society was threatened. He became its theologian, its apologist, its statesman and corrector, through sixty long years of incessant labour.

For the first thirty years (1733–1762) his work was mainly devoted to the superintendence and organization of the extensive missionary enterprises of the body in Germany, England, Denmark, Holland, Surinam, Georgia and elsewhere. It was on an island off Savannah that Spangenberg startled John Wesley with his questions and profoundly influenced his future career. One special endeavour of Spangenberg in Pennsylvania was to bring over the scattered Schwenkfeldians to his faith. In 1741–1742 he was in England collecting for his mission and obtaining the sanction of the archbishop of Canterbury. During the second half of this missionary period of his life he superintended as bishop the churches of Pennsylvania, defended the Moravian colonies against the Indians at the time of war between France and England, became the apologist of his body against the attacks of the Lutherans and the Pietists, and did much to moderate the mystical extravagances of Zinzendorf, with which his simple, practical and healthy nature was out of sympathy. The second thirty years of his work (1762–1792) were devoted to the consolidation of the German Moravian Church. Zinzendorf's death (1760) had left room and need for his labours at home. At Herrnhut there were conflicting tendencies, doctrinal and practical extravagances, and the organization of the brethren was very defective. In 1777 Spangenberg was commissioned to draw up an *idea fidei fratrum*, or compendium of the Christian faith of the United Brethren, which became the accepted declaration of the Moravian belief. As compared with Zinzendorf's own writings, this book exhibits the finer balance and greater moderation of Spangenberg's nature, while those offensive descriptions of the relation of the sinner to Christ in which the Moravians at first indulged are almost absent from it. In his last years Spangenberg devoted special attention to the education of the young, in which the Moravians have since been so successful. He died at Berthelsdorf, on the 18th of September 1792. In addition to the *Idea fidei fratrum*, Spangenberg wrote, besides other apologetic books, a *Declaration über die seither gegen uns ausgegangenen Beschuldigungen sonderlich die Person unseres Ordinarius* (*Zinzendorf*) *betreffend* (Leipzig, 1751), an *Apologetische Schlussschrift* (1752), *Leben des Grafen Zinzendorf* (1772–1775); and his hymns are well known beyond the Moravian circle.

Spangenbergs* (Halle, 1884); Gerhard Reichel's article in Herzog-Hauck's *Realencyklopädie* (ed. 1906), *s.v.* "Spangenberg"; the article by Ledderhose, in the *Allgemeine deutsche Biographie*; also MORAVIAN BRETHREN.

SPANISH-AMERICAN WAR OF 1898. For the causes leading up to the war see CUBA and UNITED STATES: *History*. On the 15th of February 1898 the U.S. battleship "Maine," which had been sent to Havana on the 25th of January, was destroyed in Havana harbour by an explosion, with a loss of 266 lives. An American board of inquiry, of which Captain W. T. Sampson was president, made an extensive examination of the wreck, and reported to the navy department on the 21st of March that the explosion was caused by an exterior mine, the principal reason for this decision being the upheaval of the ship's bottom.[1] On the 20th of April President McKinley approved a resolution demanding the withdrawal of Spain from Cuba and setting noon of the 23rd of April as the latest date for a reply to the demand. Before this could be delivered by the American minister in Madrid, the Spanish government sent him his passports. On the 22nd the president declared a blockade of Cuban ports; on the 24th the Spanish government declared war; and on the 25th the United States Congress declared that war had existed since the 21st.

The American government had begun to prepare for war as early as January: ships on several foreign stations had been drawn nearer home, and those in Chinese waters were collected at Hong-Kong; the North Atlantic squadron, the only powerful one, had been sent from Hampton Roads into the waters of Florida for manœuvres; after the destruction of the "Maine" the chief part of the ships in the Atlantic were concentrated at Key West; the battleship "Oregon" was ordered east from the Pacific; $50,000,000 was voted (March 9) "for the national defence"; steps were taken to purchase auxiliary cruisers, yachts and tugs, which were rapidly equipped; large supplies of ammunition were ordered, and Key West became an active base of preparation; Captain Sampson, senior officer of the North Atlantic squadron, was appointed its commander-in-chief with rank of acting rear-admiral; and a "flying squadron" composed of the armoured cruiser "Brooklyn" (flag), the battleships "Texas" and "Massachusetts," and the fast cruisers "Minneapolis" and "Columbia," with Commodore W. S. Schley in command, was stationed at Hampton Roads.

There was a great preponderance of large ships on the side of the United States; only in torpedo craft and small gunboats was Spain superior. The American ships were highly efficient; in Spain everything was unready; Admiral Cervera felt that to send a Spanish squadron across the Atlantic was to send it to destruction, and when he had collected his squadron (including two cruisers from Havana) at the Cape Verde Islands in March, he renewed his expostulations, in which he was supported by a council of war. But on the 24th of April he was peremptorily ordered to leave for Porto Rico, without definite instructions or plan of campaign.

The American flying squadron was held at Hampton Roads, so great was the fear of attack by Spanish ships; and armed auxiliaries and fast cruisers were employed in patrolling the coast east of New York; these could have rendered good service elsewhere, but would have been of no use in repelling an attack by Cervera's squadron had it come that way.

The joint resolution of Congress of the 20th of April had declared that the relinquishment by Spain of authority in Cuba was the object of American action; the struggle thus naturally centred about the island. All operations were thus near at hand, Havana, the real objective in Cuba, being only about 100 m. from Key West. A political reason for confining action to the western Atlantic was that an immediate attack upon the coasts of Spain might have aroused the strongly pro-Spanish sympathy of continental Europe into greater activity. The regular United States army, the only available force until war was declared and a volunteer force was authorized, had been assembled at Tampa, Florida, New Orleans and Chickamauga, Georgia, but until the control of the sea was decided, the army could not prudently be moved across the Strait of Florida. Cervera's fleet was thus the real objective of the navy, and had to be settled with before any military action could be undertaken.

Rear-Admiral Sampson left Key West early on the 22nd, and began the blockade of Havana and the north coast of Cuba as far as Cardenas, 80 m. east, and Bahia Honda, 50 m. west. His North Atlantic squadron of 28 vessels of all kinds, of which the armoured cruiser "New York" (flag), the battleships "Iowa" and "Indiana," and the monitors "Puritan," "Terror" and "Amphitrite," were the most important, and which included six torpedo-boats, was increased to 124 vessels by the 1st of July, chiefly by the addition of extemporized cruisers, converted yachts, &c.

In the Pacific, the American squadron—the protected cruisers "Olympia" (flagship of Commodore George Dewey), "Baltimore," "Raleigh" and "Boston," the small unprotected cruiser "Concord," the gunboat "Petrel," the armed revenue cutter "Hugh M'Culloch," with a purchased collier "Nanshan" and a purchased supply ship "Zafiro"—left Hong-Kong at the request of the governor and went to Mirs Bay, some miles east

[1] The Spanish authorities made an examination, but did not inspect the interior, the chief diver reporting that "the bilge and keel of the vessel throughout its entire extent were buried in the mud, but did not appear to have suffered any damage." It has been suggested that the explosion was the work of Cuban sympathizers who thus planned to secure American assistance against Spain. It was not until 1910 that Congress made an appropriation (and an inadequate one then) for raising the "Maine."

on the Chinese coast. Ordered (April 25) to begin operations, particularly against the Spanish fleet, which he was directed to capture or destroy, Dewey left Mirs Bay on the 27th, and arrived off Luzon, in the Philippines, on the 30th of April. The Spanish admiral Montojo anchored to the eastward of the spit on which are the village and arsenal of Cavite, in a general east and west line, keeping his broadside to the northward. His force consisted of the "Reina Cristina," the "Castilla" (an old wooden steamer which had to be towed); the "Isla de Cuba" and "Isla de Luzon" (protected cruisers of 1050 tons); the "Don Juan de Austria" and the "Don Antonio de Ulloa" (gunboats of about 1150 tons), and the "Marques del Duero" (of 500 tons). There were six guns (3 breech-loaders) in battery at or near Cavite.

Dewey at Manila.

Dewey stood on during the night, and passed into the Boca Grande (about 5 m. broad), paying no attention to rumours of torpedoes in a channel so broad and deep, and at midnight passed El Fraile (a large rock, 1½ m. from the south side); from which two shots were fired at him, and he was also fired at by the "Cavite" and one of the city batteries. When he sighted the Spanish squadron to the southward he ordered his transports and the revenue cutter "Hugh M'Culloch" out into the bay, and stood down in column with the "Olympia," "Baltimore," "Raleigh," "Petrel," "Concord" and "Boston" at 400-yd. intervals. When within 5000 yds. he ported his helm, and at 5.41 a.m. opened fire. He stood westwards along the Spanish line, using his port batteries, turned to starboard and stood back, gradually decreasing his distance to 2000 yds. At 7 o'clock the Spanish flagship attempted to come out and engage at short range, but was driven back by the American fire. The Spanish squadron was now in very bad plight, but the seriousness of its condition was not fully known to the American commander. At 7.35 Dewey withdrew, gave his men breakfast, and had a consultation of commanding officers. Before he re-engaged at 11.16 the "Cristina" and "Castilla" had broken into flames, so that the remainder of the action consisted in silencing the Cavite batteries and completing the destruction and demoralization of the smaller Spanish ships, which the "Petrel" was ordered in to burn. The victory was complete. All the Spanish ships[1] were sunk or destroyed. The injury done the American ships was practically nil. The Spanish lost 167 killed and 214 wounded, out of a total of 1875. The Americans had 7 slightly wounded out of 1748 men in action. Dewey took possession of Cavite, paroled its garrison, and awaited the arrival of a land force to capture Manila.

The Cuban Blockade.

The blockade of Havana had progressed without incident, beyond the capture of a number of Spanish steamers and sailing vessels,[2] and the shelling of some new earthworks at Matanzas on the 27th of April; but on the 11th of May a small action was fought at Cardeñas, in which the Americans were repulsed and Ensign Worth Bagley, the first American officer to lose his life in the war, was killed. On the same day a partially successful attempt was made, under a heavy fire from the shore, to cut the cable between Cienfuegos and Havana.

Cervera had left the Cape Verde Islands on the 29th of April with four armoured cruisers, the "Almirante Oquendo," "Infanta Maria Theresa" and "Vizcaya" (sister ships of 7000 tons) and the "Cristobal Colon" (same size; differently equipped) and three torpedo-boat destroyers—a type not then represented in the American navy—"Furor," "Terror" and "Pluton." On hearing (May 1) of Cervera's departure, Sampson went east 1000 m. to San Juan, Porto Rico, with the armoured cruiser "New York," the battleships "Iowa" and "Indiana," the cruisers "Montgomery" and "Detroit," and one torpedo-boat. In going east he calculated on using a speed of 10 knots, on getting to San Juan on the 8th, about the time the Spaniards would reach its longitude, and if they were not there, on returning off Havana before they could get to Havana harbour. He wished to prevent Cervera's refitting at San Juan, from which place the American coast would be within easy reach, New York being only about 1400 m. away. But the speed of the American squadron fell short of Sampson's expectation; he reached San Juan on the 12th, stood in to see if Cervera was in the harbour, and opened fire upon the fortifications. He did not press the attack since Cervera was not present, and at once started back for Havana without news of Cervera, who was then in fact off Martinique, with orders to go to San Juan. When he heard that Sampson was at San Juan, he steamed to Curaçao, where he arrived on the 14th of May and where the authorities allowed him to coal. He reached Santiago de Cuba early on the 19th without being sighted *en route* by any of the American scouts, though several were in the vicinity. Sampson thought the Spanish squadron might have returned to Spain.[3] But he learned that the enemy had not turned back, on the night of the 15th, when a telegram from the navy department directed him to proceed with all despatch to Key West. He got there on the afternoon of the 18th, and found the flying squadron ("Brooklyn" (flag), "Massachusetts," "Texas," and "Scorpion"), which left on the next morning (19th) for Cienfuegos, then regarded by the navy department as the certain objective of the Spanish squadron. The battleship "Iowa," the gunboat "Castine," the torpedo-boat "Dupont" and the collier "Merrimac" sailed to join Schley on the 20th, and gave him a force sufficient to meet Cervera. Sampson was advised by the department (on the 20th) to "send by the 'Iowa' to Schley to proceed off Santiago de Cuba with his whole command, leaving one small vessel off Cienfuegos," but he directed Schley in an order of the 21st if he was satisfied that Cervera was not at Cienfuegos, to proceed with all despatch to Santiago, and if the Spanish squadron was there, to blockade it.

The Search for Cervera's Squadron.

Commodore Schley arrived off Cienfuegos on the 22nd, and held to the opinion that Cervera was there until the 24th, when Commodore M'Calla of the "Marblehead" communicated with the insurgents some miles westwards, and learned the truth. Schley started that evening for Santiago, 300 m. distant, but on the afternoon of the 26th was 20 m. south of the port. Early on the 27th Schley received a despatch from the navy department suggesting that the Spanish squadron was in Santiago and bidding him see "that the enemy, if therein, does not leave without a decisive action." Schley replied ". . . cannot remain off Santiago present state squadron coal account . . . much to be regretted cannot obey orders of department. . . forced to proceed for coal to Key West by way of Yucatan Passage"; in the controversy that arose out of these events Schley's critics insisted that the "Iowa" and the "Massachusetts" had at this time enough coal to carry them three times the distance from Santiago to Key West.

Sampson with the "New York" had arrived early on the 28th of May off Key West. When Schley's telegram, which had much disturbed the Washington officials, was forwarded to Sampson, he secured permission to go at once to Santiago with the "New York" and "Oregon" (which had arrived at Key West on the 26th of May in excellent condition after her voyage of nearly 16,000 m. from the Pacific) to turn back Schley's heavier ships. Before he started he received a telegram from Schley stating that he would remain off Santiago. It is now known from the documents published by Admiral Cervera that the Spanish squadron, in the interval preceding the 28th, when Schley arrived in sight of the port, was on the point of leaving Santiago. On the morning of the 29th two Spanish cruisers were seen a short distance within the entrance, and on the 31st Schley, with the "Massachusetts," "Iowa" and "New Orleans," stood in and made an attack upon these and the batteries at long range (8500–11,000 yds.). On the 30th Sampson, leaving a squadron on the north side under Commodore Watson, stood for

[1] Three of the best were afterwards raised and repaired by American engineers.

[2] The "Buenaventura," the first prize of the war, was taken by the gunboat "Nashville" off Key West on the 23rd of April.

[3] A telegram (not received by Cervera) had been sent to Martinique on the 12th of May, authorizing the squadron's return.

Santiago at a speed of 13 knots. He arrived early on the 1st of June and work was at once begun on the preparations for sinking the collier " Merrimac " in the entrance channel, which was less than 200 ft. broad in parts available for ships. The preparations for a quick sinking were chiefly carried out by naval constructor Richmond P. Hobson, who went in, in the early morning of the 3rd of June, with a crew of seven men. The steering-gear was disabled by a shell, and the ship drifted too far with the tide and was sunk in a broad part of the channel where it did not block the egress of Cervera's squadron. Cervera sent word to Sampson that Hobson and his men, who had been captured, were unhurt. They were exchanged on the 7th of July.

On the 6th of June the batteries at the entrance were bombarded and their weakness was ascertained. Sampson thereupon placed, every evening, a battleship (relieved every two and a half hours) close in, with a searchlight turned on the channel, making it impossible, as Cervera. afterwards said, for the Spanish squadron to escape by night. The port of Guantánamo, 40 m. east of Santiago, was occupied by the " Marblehead " and " Yankee " on the 7th, a battalion of marines from the transport " Panther " landed there on the 10th, and the port was used thereafter as a base and coaling station. On the 14th the Spanish land forces retired before an expedition of the American marines, who remained in occupation until the 5th of August.

The United States Fleet before Santiago.

A blockade of San Juan, Porto Rico, by one or two fast ships was kept up on account of the presence there of the destroyer " Terror," but this vessel, coming out (June 22) with a gunboat to attack the auxiliary cruiser " St Paul," suffered so severely that she could hardly return to port, and was thereafter unserviceable.

When war was declared the total military forces of the United States consisted of 27,822 regulars and 114,602 militia. An act of the 22nd of April had authorized the president to call upon the states and Territories for men in proportion to their population, the regimental and company officers to be named by the governors of the states, the general and staff officers by the president. A first call was made for 125,000 men, and a month later a second call for 75,000. On the 26th of April large additions to the regular army were sanctioned for the war. The quotas were filled with extraordinary rapidity, and in May 124,776 had volunteered. The troops were concentrated chiefly at Chickamauga, Georgia, at Camp Alger, Virginia, and at Tampa, Florida, which was selected as the point for the embarcation of the expeditionary force for Cuba, and where Major-General W., R. Shafter was in command. With the exception of unimportant small expeditions, everything was delayed until control of the sea was assured, though some thirty large steamers were held in readiness near Tampa. After the arrival of Cervera at Santiago, the blockade of his squadron and the request (June 7) of Admiral Sampson to send a land force for co-operation, the troops embarked on the 7th and 8th of June, but a start was not made until the 14th, owing to a false report that Spanish war-ships were in Nicholas Channel. On the 29th the fleet of 32 transports, under convoy, arrived off Santiago. The whole force consisted of about 17,000 officers and men, 16 light field-guns, a train of heavier pieces, and some 200 vehicles. General Shafter selected Daiquiri, about 18 m. east of Santiago, for the point of landing, and the harbour entrance (preferred by Sampson) was disregarded. The fleet furnished all its available boats, and on the 22nd–25th the army was landed on a rough coast with scarcely any shelter from the sea; after the first day Siboney, 7 m. nearer Santiago, was used as well as Daiquiri. With the exception of three volunteer regiments (the 1st Volunteer Cavalry, known as the Rough Riders, of which Theodore Roosevelt was lieutenant-colonel; the 2nd Massachusetts and the 71st New York Volunteers), these troops were composed almost wholly of regulars, most of whom had served on the plains against the Indians. Soon afterwards more voluuteers arrived.

Preparations for a Land Campaign.

No opposition was made to the landing and the small Spanish contingents at Daiquiri and Siboney were withdrawn without doing any damage to the equipment of the railway which ran from Santiago to the iron mines at these points. The American troops (commanded by Major-General Joseph Wheelcr until the 29th, when General Shafter landed) pushed forward, a soon as they landed, and found a small Spanish rearguard which was covering the concentration of outlying detachments on Santiago and which was entrenched $2\frac{1}{2}$ m. beyond Siboney, at Las Guásimas. Brigadier-General S.B.M. Young with 964 dismounted cavalry engaged (June 24), and after a sharp action, in which he lost 16 killed and 52 wounded, drove back the enemy, of whom 11 were killed out of some 500 engaged. The advance was slow and a week elapsed before Shafter was ready to fight a battle in front of Santiago. Here the defenders, under General Arsenio Linares, held two positions, the hill of San Juan, barring the direct road to Santiago, and the village of El Caney, to the northward of the American position at El Pozo. The plan of attack on the 1st of July was Shafter's, but owing to the illness of Shafter the actual command was exercised by the subordinate generals, Joseph Wheeler, H. W. Lawton and J. F. Kent. General Lawton's division was to attack and capture El Caney, and thence move against the flank and rear of the defenders of San Juan, which would then be attacked in front by Kent and Wheeler from El Pozo. But Lawton for nine hours was checked by the garrison of El Caney, in spite of his great superiority in numbers (4500 to 520); at 3 p.m. the final assault on El Caney was successfully delivered by General A. R. Chaffee's brigade. Only about 100 of the Spanish garrison escaped to Santiago; about 320 were killed or wounded, including General Vara del Rey, who, with a brother and two sons, was killed. In the meantime Wheeler and Kent had an equally stubborn contest opposite San Juan hill, where, in the absence of the assistance of Lawton, the battle soon became a purely frontal-fire fight, and the rifles of the firing line had to prepare the attack unaided. The strong position of the Spaniards, gallantly defended by about 700 men, held out until 12.30, when the whole line of the assailants suddenly advanced, without orders from or direction by superior authority, and carried the crest of the Spanish position. A notable part in the attack was taken by the 1st Volunteer Cavalry or " Rough Riders," commanded by Colonel Leonard Wood and Lieut.-Colonel Theodore Roosevelt. The Spaniards had no closed reserves, and their retreat was made under a devastating fire from the Americans on the captured hills. On the American side over 1500 men out of 15,000 engaged, including several of the senior officers, were killed or wounded; and in one of Kent's brigades three successive commanders were killed or wounded. On the Spanish side, out of the small numbers engaged, over 50% were out of action. Linares himself was severely wounded, and handed over the command to General José Toral. The Cubans on the American right failed to prevent General Escario from entering Santiago with reinforcements from the interior, and at the beginning of the investment General Toral's forces numbered about 10,000 men of the army and a naval contingent from the fleet.

Though victorious, the American army was in danger: after great fatigue under a tropical sun by day, the time spared at night from digging trenches was spent on a rain-soaked ground covered with thick vegetation; the soldiers' blankets and heavy clothing had been cast aside in the attack; and there was insufficient food, because it was difficult to haul supplies over the one poor road from the base of supplies at Siboney. There was even discussion of retiring to a point nearer Siboney. Brisk firing was continued on the 2nd and 3rd of July, with a considerable number of casualties to the Americans. On the morning of the 3rd a demand was sent to the Spanish commander to surrender, with the alternative of a bombardment of the city to begin on the 4th. This in effect had already begun on the 1st, when Admiral Sampson fired a number of 8-in. shells from a point 3 m. east of the harbour entrance over the hills into the city, using a range of about $4\frac{1}{2}$ land miles. The result of this and the threat of General Shafter was an exodus of many thousands of civilians towards El Caney, where the American supplies were heavily taxed to support them.

Investment of Santiago on the Land Side.

On the morning of the 3rd of July Sampson, in his flagship the "New York," left the fleet to confer with General Shafter at Siboney with regard to combined operations at the harbour entrance.[1] At 9.31, when he had gone about 5 m., the "Maria Teresa" was seen coming out. The ships in front of the port were the yacht "Gloucester," the battleships "Indiana," "Oregon," "Iowa," and "Texas," the armoured cruiser "Brooklyn" and yacht "Vixen," in the order named from east to west, making a semicircle about 8 m. in length. The "Massachusetts" and "Suwanee" were coaling at Guantánamo. The "Iowa" hoisted the signal "Enemy coming out." All at once stood in toward the Spanish ships, which were standing westwards along shore, and began a heavy fire. The "Maria Teresa" (flagship) was followed at 800-yd. intervals by the "Vizcaya," "Colon" and "Oquendo." They were firing vigorously, but most of their projectiles went far beyond the American ships. The "Brooklyn" (flag of Commodore Schley, the senior officer present) made a turn to starboard, which seems to have caused the "Texas" to stop and back, and to have given the "Colon" the opportunity of passing almost unscathed. The "Maria Teresa" and "Oquendo" had taken fire almost at once, and, as their water mains (outside the protective deck) were cut, they were unable to extinguish the flames: they were run ashore at 10.15 and 10.20 respectively, about 6½ m. west of Santiago, burning fiercely. The "Vizcaya" and "Colon" were still standing westwards. Cervera's destroyers, the "Pluton" and "Furor," had come out last, some distance behind the "Oquendo," and were received with a heavy fire from the "Indiana" and from the unarmoured "Gloucester," which engaged them at close quarters. They attempted to close, but were cut to pieces. The "New York," Sampson's flagship, had passed, and stood on signalling the "Iowa" and "Indiana" to go back and watch the port, lest an attack be made on the American transports. The torpedo-boat "Ericsson" was ordered to rescue the men from the two Spanish ships ashore, and the flagship, with all the others, stood on in pursuit of the "Vizcaya" and "Colon." The "Vizcaya" hauled down her colours off Aserraderos, 15 nautical miles west of Santiago, and was there run ashore burning about 11.15 a.m. The "Iowa" was ordered to stop and rescue her men, and the "Oregon," "Brooklyn" and "Texas" (and behind them the flagship) settled down to the chase of the "Colon," some 6 m. ahead of the nearest American ship. She was, however, slacking her speed, and at 12.40 the "Oregon" opened with her 13-in. guns at a range of 9000 yds., as did also the "Brooklyn," with her 8-in. When the "Oregon" had fired five shells, the "Colon" hauled down her colours, and was beached at the mouth of the Rio Turquino, where in spite of endeavours to recover her, she became a total wreck. The whole Spanish fleet was destroyed; Admiral Cervera was taken prisoner; Captain Villamil, commanding the torpedo flotilla, went down with his ship: and Captain Lazaga of the "Oquendo" was drowned. Over 500 Spaniards were killed or wounded, and the survivors (except a few who escaped to Santiago) were prisoners. On the American side only one man was killed and ten were wounded, and no ship received serious injury.

Naval Battle of Santiago.

After the naval victory combined operations were arranged for attacking the batteries of the harbour, but little more fighting occurred, and eventually a preliminary agreement was signed on the 15th, and the besiegers entered Santiago on the 17th. In accordance with the terms of the capitulation, all the Spanish forces in the division of Santiago de Cuba surrendered and were conveyed to Spain. The total number amounted to about 23,500, of whom some 10,500 were in the city of Santiago. The exposure of the campaign had begun to tell in the sickness of the Americans: yellow fever had broken out to some extent; and no less that 50% were attacked by the milder forms of malarial fever. The army, indeed, was so weakened by illness that the general officers united in urging its removal from Cuba. Major-General Nelson A. Miles, the general-in-chief, had arrived with reinforcements on the 12th of July, but the majority of these men were retained on board ship.

[1] Shafter had urged that the squadron should enter the harbour and take the city. Sampson (and the Navy department) was unwilling to risk losing a ship in the well-mined harbour and wanted the army to move on the forts and give the American squadron an opportunity to drag the harbour for mines.

The fleet and the army gathered in Guantánamo Bay; and a new flying squadron, the "eastern squadron," was organized under Commodore John C. Watson, to proceed by way of the Mediterranean to the Philippines, threatening the Spanish coast, in order to meet a Spanish "reserve squadron," which had been formed towards the end of May, and which was to be sent on to the eastern coast of the United States, and thence to Cuba, but which was diverted toward the Philippines, and left Cadiz, on the 16th of June, for the East. This squadron turned back on the 8th of July after hearing the news of the Spanish defeat at Santiago.

On the 7th of May a telegram had been received from Dewey at Manila: "I control bay completely, and can take city at any time, but I have not sufficient men to hold." The cruiser "Charleston" and the steamer "Peking," with ammunition, supplies and troops, were sent to him at once. Major-General Wesley Merritt, to whom was assigned the command of the troops for the Philippines, first requested a force of 14,000, and afterwards asked for 20,000 men. On the 25th of May the first troops, 2491 in number, under Brigadier-General T. M. Anderson, sailed in three transports from San Francisco, touched at Honolulu, and were convoyed thence by the "Charleston." On the 20th of June possession was taken of the island of Guam, and on the 30th of June the ships arrived in Manila Bay. A second detachment of troops, 3586 in number, under Brigadier-General F. V. Greene arrived on the 17th of July; on the 25th of July General Merritt, who had been appointed governor-general, arrived; and on the 31st the five transports with which he had left San Franciseo arrived with 4847 men, making nearly 11,000 men at Manila, with 5000 more on the way. General Merritt moved his forces from Cavite, and established an entrenched line within a thousand yards of the Spanish position at Manila, from which, on the night of the 31st of July, a heavy fire of musketry and artillery was opened, causing a loss to the Americans of 10 killed and 43 wounded, and for the next few days night-firing was frequent from the Spanish lines. On the 7th of August, a joint note from Dewey and Merritt, announcing that bombardment might begin at any time after forty-eight hours, and affording opportunity for the removal of non-combatants, was sent to the Spanish captain-general, Fermin Jaudenes, who replied that he was surrounded by the insurgents,[2] and that there was no place of refuge for the sick and for the women and children. A second joint note demanding surrender was declined by the Spanish commander, who offered to refer it to Madrid. This was refused, and preparations were made for an attack. There were 13,000 troops within the city fortifications, but with the strong fleet in front, and with the beleaguering force of Americans and insurgents ashore, resistance was hopeless. When the combined assault of army and navy was made on the 13th there was no great resistance, and a white flag was hoisted at 11 o'clock, within one and a half hours after the fleet opened fire, a formal capitulation being signed the next day, the 14th of August. The total loss of the Americans during the whole campaign was 20 killed, 105 wounded.

Capture of Manila.

Immediately after the surrender of Santiago (July 17), preparations were made for the invasion of Porto Rico with 3500 troops which had been sent as reinforcements to Santiago, but had not landed. They were largely reinforced and left Guantánamo, under General Miles, on the 21st of July, convoyed by a strong squadron.

Operations in Porto Rico.

[2] On the 19th of May, Emilio Aguinaldo, who had been at Hong-Kong, had landed from one of the American vessels at Cavite, and on the 1st of July, when the American troops landed, had proclaimed himself president of the Philippine Republic. The political attitude which he assumed was not sanctioned by the American autnorities. At the head of the insurgents he had instituted a close siege of Manila.

Fajardo, at the extreme north-eastern end of the island, was given out as the objective point of the expedition, but after sailing the plans were changed, and the towns on the south side were occupied, practically without resistance. The attitude of the population was exceedingly friendly, and opposition was not met until advance was begun northward. The troops were divided into four columns, advancing from Guanica around the western end of the island to Mayaguez: from Arroyo at the eastern end to meet the San Juan road at Cayey; from Ponce by the fine military road, 70 m., to San Juan; and the fourth column by way of Adjuntas and Utuado, midway of the island. The various movements involved several skirmishes, the chief opposition being met by the western column on the 10th of August, and by the column from Ponce on the 9th, when the Americans lost 1 killed and 22 wounded; the Spanish, 126 killed and wounded, and over 200 prisoners. A further advance on the San Juan highway would probably have developed greater resistance, but news of the suspension of hostilities intervened. The total American loss had been 3 killed and 40 wounded. On the 12th of August operations were begun by the "Newark" and other vessels against Manzanillo. But during the night news arrived of the signing of the peace protocol on the 12th, and of an armistice, of which the Americans were informed by the Spanish commander under a flag of truce.

The total American loss was—in the navy, 1 officer, 17 men killed; in the army, 29 officers, 440 men. The health of the American fleet was kept remarkably. Its average strength during the 114 days of hostilities was 26,102; the deaths from disease during this time were 56, or at the rate of 7 per 1000 per year. As nearly the whole of the service was in the tropics, and in the summer or wet season, this is a convincing proof of the efficiency in sanitary administration. The army did not fare so well, losing by disease during May, June, July and August, 67 officers and 1872 men out of an average total of 227,494. Its larger proportion of illness must of course be ascribed, in part, to its greater hardships. The war department was accused of gross maladministration; but the charges were not upheld by an investigating committee. The lack of proper preparation by the war department and the ignorance and thoughtlessness of the volunteers were the principal reasons for the high death-rate in the army.

Losses of the Americans.

For the terms of the peace and the results of the war see UNITED STATES; PHILIPPINE ISLANDS; CUBA; PORTO RICO.

The literature of the Spanish-American War is voluminous: amongst the principal sources of information may be mentioned; The annual reports of various departments for 1898, especially the *War Notes* of the Office of Naval Intelligence, Washington, which include Spanish translations, and the appendix to the report of the Bureau of Navigation; R. H. Titherington, *A History of the Spanish-American War* (New York, 1900); H. C. Lodge, *Story of the Spanish War* (New York, 1899); H. W. Wilson, *The Downfall of Spain* (London, 1900); W. A. M. Goode, *With Sampson through the War* (London, 1899); J. Wheeler, *Santiago Campaign* (Philadelphia, 1899); Theodore Roosevelt, *The Rough Riders* (New York, 1899); C. D. Sigsbee, *Personal Narratives of the Battleship Maine* (New York, 1899); R. A. Alger, *Spanish-American War* (New York, 1900); Gomez Nuñez, *La Guerra hispano-americana* (Madrid, 1900); H. Kunz, *Taktische Beispiele aus den Kriegen der Neuesten Zeit* II. (Berlin, 1901); Admiral Plüddemann, *Der Krieg um Cuba 1898* (Berlin); John D. Long, *The New American Navy* (2 vols., New York, 1903); John R. Spears, *Our Navy in the War with Spain* (ibid., 1898); Bujac, *Précis de quelques campagnes contemporaines*, IV. (Paris, 1899); and the *Century* and *Scribner's* magazines for 1898 and 1899 *passim*.

SPANISH BROOM, a handsome shrub with long switch-like green few-leaved or leafless branches and large yellow sweet-scented papilionaceous flowers. It is a member of the Pea family (Leguminosae), and known botanically as *Spartium junceum*. It is a native of the Mediterranean region and the Canary Islands, and is often cultivated. The whole plant, but especially the flower shoots and seeds (*herba et semen genistae hispanicae vel junceae*), have a bitter taste and tonic and diuretic properties, and were formerly used medicinally. The fibres of the young stems were used in making nets, carpets, mats, baskets, &c.

SPANISH REFORMED CHURCH (Iglesia española reformada), a small community of Protestants in Spain organized on the model of the Anglican Church. This body of Spanish Episcopalians had its origin in a congregation which met for the first time, in June 1871, in the secularized church of San Basilio at Seville, under the leadership of Francisco Palomares, a priest who had left the Roman communion. Before long it was joined by numbers of lay people and several clergymen, including Juan Cabrera, an ex-Roman priest, who had for some time been a Presbyterian minister. In July 1878 a memorial was presented to the Lambeth Conference by nine congregations in Spain and Portugal (see below) asking for the episcopate. The reply expressed the sympathy of the bishops, but only suggested that Dr Riley, recently consecrated by the Protestant Episcopal Church of the United States to minister to the reformed congregations in Mexico, should be invited to visit them and ordain and confirm for them. Archbishop Tait wrote a formal letter to Bishop Riley to this effect, and the request was complied with. A second petition for the episcopate was sent to the Irish bishops in 1879, and early in 1881, at their request, Lord Plunket paid his first visit to the Spanish Reformed Church, though nothing immediately resulted from it. In 1880 the first "synod" of the Church was held, under the presidency of Bishop Riley; the principles of the Church were laid down, Señor Cabrera was chosen bishop-elect, the preparation of a liturgy was begun, and the Thirty-nine Articles of Religion of the Church of England, with certain modifications, were formally adopted as a standard of doctrine. Archbishop Plunket continued his efforts on their behalf; and at length the Irish bishops, having again received from them a petition for a bishop, brought the matter before the Lambeth Conference of 1888. The conference deprecated "any action that does not regard primitive and established principles of jurisdiction and the interests of the whole Anglican communion." The archbishop interpreted this as a modified consent; but the Irish bishops understood it otherwise, and again declined to consecrate a bishop for them. Meanwhile the movement prospered, being largely helped with money from friends in England. The foundation-stone of a new church was laid in Madrid in 1891, on the site of the *Quemadero*, where the *autos de fé* were formerly held; and after considerable legal and other difficulties, religious toleration in Spain being still imperfect, it was dedicated and opened for service. At length, at the meeting of the Irish House of Bishops on the 21st of February 1894, a letter was read from the archbishop of Dublin and the bishops of Clogher (C. M. Stack) and Down (C. Welland), in which they declared their intention, unless a formal protest were made by the bishops, or by the general synod, to consecrate bishops for the Reformed churches in Spain and Portugal, subject to certain conditions being fulfilled by those churches. The bishops resolved, *nemine contradicente*, although the bishops of Derry (W. Alexander, subsequently primate of Armagh) and Cork did not vote, that they would not regard such action as "an indefensible exercise of the powers entrusted to the episcopate"; and the general synod passed a resolution leaving the matter in the hands of the bishops. Accordingly, on the 23rd of September 1894, the three bishops laid hands on Señor Cabrera. The matter occasioned no little stir in the English Church, more especially as the Old Catholic bishops (see OLD CATHOLICS) had recently refused to take any part in the matter. It called forth a letter of protest and repudiation from Lord Halifax, as president of the English Church Union, to Cardinal Monescillo, archbishop of Toledo; and this in turn evoked a letter from Cardinal Vaughan, which was widely circulated in Spain.

The consecration of Bishop Cabrera certainly produced, from the point of view of Anglican churchmen, a somewhat anomalous state of things, and the action, or inaction, of the Irish bishops laid them open to criticism from many who were not unfriendly to such movements (see *e.g.* Bishop John Wordsworth, *Ministry of Grace*, pp. 176–177, London, 1901). Objection was made to the act as contrary to church order, and as unjustifiable in view of the nature of the Spanish Reformed Church itself. As regards the latter, it is true that the Prayer-book of the body (first made in 1881 and published in a revised form in 1889) cannot really justify the claim made on its behalf as a "revised Mozarabic rite": it contains indeed many beautiful prayers from the Mozarabic and other offices, but its doctrinal teaching is more unambiguously "Protestant" than that of the English Prayer-book. The Church possessed in 1906 ten congregations with some dozen clergy.

Lusitanian Church.—A similar movement began in Lisbon in 1867, owing to the work of a Spanish priest there, Señor Mora; and at first its success was even greater than the movement in Spain, in spite of the fact that Portuguese priests who left the Roman communion had either to leave Portugal or to become subjects of another power. In 1875 the adherents of this movement threw in their lot with their Spanish brethren, and when Bishop Riley visited them in 1878 the Portuguese members organized themselves as the "Lusitanian Church," and the Rev. T. Godfrey Pope, D.D. (d. 1902), the English chaplain at Lisbon, was subsequently chosen by them as president of the synod. A request made to the Irish bishops in 1897 for the consecration of Canon Pope as their bishop led to an examination of the Lusitanian Prayer-book, which was found to be even more defective from the Anglican point of view than that of the Spanish Reformed Church. Consequently no action was taken. In 1906 the Church had only some 500 adherents with five clergy.

(London, 1899); *Officios divinos, &c. en la iglesia española reformada* (Madrid, 1898; Eng. trans., Dublin, 1889; new ed., 1894); *Divine Offices and other Formularies of the Reformed Episcopal Churches of Spain and Portugal* (London, 1882); *Church Quarterly Review*, xxxviii. 283 (July 1894), art. "The Proposed Episcopate for Spanish Protestants."

SPANISH SUCCESSION, WAR OF THE, the name given to the general European war which began in 1701 and ended with the Treaties of Utrecht and Rastatt in 1713–14. The war in its *ensemble* is the typical "war with limited aim," carried out by professional armies in the interests of sovereigns and their cabinets and (except in the last stages of the war in northern France) enlisting no more than the platonic sympathies of the various peoples whose rulers were at war. Nevertheless, its monotonous round of marches and sieges is now and then quickened by the genius of three great soldiers, Marlborough, Eugene and Villars, and Peterborough and Galway, Catinat and Vendôme, though less highly gifted, were men of unusual and conspicuous ability. As usual in these wars, manœuvres, threats and feints played the principal part in field warfare. The soldiers of those days were too costly to be squandered on indecisive battles, and few generals of the time either knew how to make a battle a means of definitively settling the quarrel or had the influence and force of character to extort from their sovereigns permission to play for high stakes. The tangible assets, at the conclusion of peace, were fortresses and provinces; and the effective seizure of fortresses and provinces, "here a little, there a little," was in most cases the principal object with which kings and princes made war. Nevertheless, at the time of the Spanish Succession War the generals had not yet wholly reconciled themselves to their new position of superior chess-players. Moreover, the object of the war, at least in the case of England and Holland, was less to add a few cities and districts to their own domains than to cripple the power of Louis XIV. The ambition of the *Grand Monarque* had stepped beyond these narrow limits, and by placing on the throne of Spain his grandson Philip he had brought into politics the fear not merely of a disturbance but of an entire overthrow of the "balance of power." Thus the instrument of his ambition, his magnificent army, was (above all for England) an object in itself and not merely an obstacle to the attainment of other objects. Many of the allies, however, had good reason to fear for their own possessions, and others entered the alliance with at least the hope of acquiring a few material gains at small expense. On the side of the allies therefore, throughout the war, there was a perpetual struggle between offensive activity and defensive passivity, and within the category of "activity" two very different forms of offensive alternately prevailed, the decision of the main question by the sword and the seizure of a minor object by stratagem. Were it not for the existence of this struggle, indeed, the war would be devoid of interest. Later in the 18th century there was, as a rule, no such struggle, for the grander form of offensive died out completely, and the feebler form was easily reconciled with the requirements of passive defence. But in 1700 the true spirit of war—in a leader of the greatness of Marlborough at least—was not yet entirely smothered by chicane.

The action of Louis XIV. in the matter of the Spanish succession was foreseen, and William III. of England had devoted his last years to providing against the emergency by the formation of a coalition to deal with it, and the production of a claimant for the Spanish throne, the archduke Charles. The coalition naturally grew out of the Grand Alliance (see Grand Alliance, War of the), and consisted of Austria, some of the German states, Great Britain, Holland, Denmark and Portugal. On the other side Louis XIV. was supported by Spain—where Philip, recognized as heir by the dying Charles II., had been promptly installed—Bavaria and Cologne. A doubtful ally was the duke of Savoy, whose policy was to secure and aggrandise himself by adhering at each moment to the stronger party. The alliance of Louis with the discontented prince of Hungary and Transylvania Rakocsy was rather an impediment to his enemy than a direct assistance to himself.

The war began, to all intents and purposes, with the handing over of the fortresses in the Spanish Netherlands to the French in March 1701. England and Holland at once began their preparations, but neither state was able to put an army in the field in the year—England because her peace-time army was absolutely insignificant, and Holland because she dared not act alone. In Italy, however, the emperor took the initiative, and an Austrian army under Prince Eugene, intended to overrun the Spanish possessions in the Peninsula, assembled in Tirol in the early summer, while the opposing army (French, Spaniards and Piedmontese), commanded by Marshal Catinat, was slowly drawing together between the Chiese and the Adige. But supply difficulties hampered Eugene, and the French were able to occupy the strong positions of the Rivoli defile above Verona. There Catinat thought himself secure, as all the country to the east was Venetian and neutral. But Eugene, while making ostentatious preparations to enter Italy by the Adige or Lake Garda or the Brescia road, secretly reconnoitred passages over the mountains between Roveredo and the Vicenza district. On the 27th of May, taking infinite precautions as to secrecy, and requesting the Venetian authorities to offer no opposition so long as his troops behaved well, Eugene began his march by paths that no army had used since Charles V.'s time, and on the 28th his army was on the plains.

Carpi and Chiari, 1701.

His first object was to cross the Adige without fighting, and also by ravaging the duke of Mantua's private estates (sparing the possessions of the common people) to induce that prince to change sides. Catinat was completely surprised, for he had counted upon Venetian neutrality, and when in the search for a passage over the lower Adige, Eugene's army spread to Legnago and beyond, he made the mistake of supposing that the Austrians intended to invade the Spanish possessions south of the Po. His first dispositions had, of course, been for the defence of the Rivoli approaches, but he now thinned out his line until it reached to the Po, and after five weeks' cautious manœuvring on both sides, Eugene found an unguarded spot. With the usual precautions of secrecy (deceiving even his own army), he crossed the lower Adige in the night of the 8th–9th of July, and overpowered the small cavalry corps that alone was encountered at Carpi (July 9). Catinat at once concentrated his scattered army backwards on the Mincio, while Eugene turned northward and regained touch with his old line of supply, Roveredo-Rivoli. For some time Eugene was in great difficulties for supplies, as the Venetians would not allow his barges to descend the Adige. At last, however, he made his preparations to cross the Mincio close to Peschiera and well beyond Catinat's left, with the intention of finding a new supply area about Brescia. This was executed on the 28th of July, Catinat's cavalry, though coming within sight of Eugene's bridges, offering no opposition. It seems that the marshal was well content to find that his opponent had no intention of attacking the Spanish possessions in the Peninsula, at any rate Catinat fell back quietly to the Oglio. But his army resented his retreat before the much smaller force of the Austrians and, early in August, his rival Tessé reported this to Paris, whereupon Marshal Villeroy, a favourite of Louis, was sent to take command. The new commander was perhaps the least competent of all the French senior officers, and ere long he attacked Eugene in a well entrenched position at Chiari (Sept. 1), and was thoroughly defeated, with a loss, it is said, of 3000 to the Austrians' 150. Both armies then stood fast until the exhaustion of supplies compelled them to move, when Villeroy retreated to the Adda. Both Villeroy and Catinat (who had remained with him as second-in-command), warned the king of the duplicity of the duke of Savoy, who, for all the reckless bravery that he had displayed in attempting to storm his cousin's entrenchments, was in reality already intending to change sides.

As yet there was no declaration of war by either party. Preparations were made by both sides during the year, most vigorously of all by Louis, who set on foot no less than 450,000 regulars and embodied militia, and had always prided himself on being first in the field. But the début was disheartening, and in the winter a fresh mishap befell the French. Eugene, who had taken up his winter quarters in such a way as to play upon Villeroy's fears of an invasion of Naples, surprised Cremona on the night of the 1st of February 1702, and, after a confused fight, drew off, taking with him Villeroy as a prisoner. The brave but incapable marshal was however little loss, and the French troops, many of them surprised in their beds, had yet managed to expel Eugene's men. The rest of the French army, instead of marching to the guns in the 19th-century manner, retreated in the 18th-century manner, while Eugene quietly resumed his winter quarters and his blockade of Mantua.

With the year 1702 the real struggle began. Villars and one or two others of Louis's best counsellors urged the king to concentrate his attention on the Rhine and the Danube, where, they pointed out, was the centre of gravity of the coalition. This advice was disregarded, and with political aims, which it is hard to imagine, the largest French army was employed on the side of the Meuse, while the Rhine front was entrusted to smaller forces acting on the defensive. In Italy the balance of power remained unchanged, except that one of Louis's best generals, Vendôme, was sent to replace the captured Villeroy. In the Low Countries, Ginckell, earl of Athlone, the interim commander of the allies (English, Dutch and minor German states), was at the outset outmanœuvred by the French (Boufflers), and although, in fact, the material advantage was with the allies, who captured Kaiserswerth on the Rhine, the momentary threat of a French invasion had a lasting effect on the Dutch authorities, whose timidity thereafter repeatedly ruined the best-laid schemes of Marlborough, who was obliged to submit to their obstruction and their veto. This handicap, moreover, was not the only one under which Marlborough suffered. Unless it is realized and borne in mind that the great captain was struggling against factiousness and intrigue in England and from jealousies, faint-heartedness and disagreements amongst the states who lent their contingents to his miscellaneous army, the measure of his achievements in ten years seems small. But in fact it was marvellous. Under 18th-century conditions of warfare, and with an army so composed that probably no other man in Europe could have held it together at all, obstructed and thwarted at every turn, he yet brought Louis XIV. and France to the very edge of ruin.

Marlborough's First Campaign.

In this theatre of war the French, in concert with the garrisons of the Spanish Netherlands, had fortified a line of defence more than 70 m. long from Antwerp to Huy, as well as another line, longer but of only potential importance, from Antwerp along the Scheldt-Lys to Aire in France. Besides the "lines of Brabant" Boufflers held all the Meuse fortresses below Huy except Maestricht. Marlborough concentrated 60,000 men (of whom 12,000 only were British) about Nijmegen in June, and early in July, having made his preparations, he advanced directly by Hamont on Diest. Boufflers, who had drawn together his field army in Gelderland for the relief of Kaiserswerth and the late attack on the earl of Athlone, hastily fell back, in order to regain touch with the Brabant lines. Marlborough, with the positive object of bringing his opponent to battle at a disadvantage, won the race and awaited the arrival of Boufflers' tired army to strike it a paralysing blow. But at the critical moment the Dutch deputies forbade the battle, content to see the army that had threatened Holland with invasion driven off to a safe distance without bloodshed (July 22). Ten days later Boufflers, thus easily let go, again advanced from Diest, was trapped by Marlborough and released by the Dutch. This time it was a disobedient general, not the civilian commissioners at headquarters, who did the mischief, but after this second experience Marlborough thought it prudent to pacify the Dutch by besieging the Meuse fortresses, several of which fell in rapid succession (September–October). His return to the Meuse led Boufflers to suppose that the enemy had a Rhine campaign in view and he at once sent off a corps under Tallard towards Cologne, standing on the defensive himself at Tongres, where for the third time in the campaign he was outmanœuvred by Marlborough and saved by the deputies at Marlborough's headquarters. Boufflers hurriedly fell back within the defended area of the lines of Brabant, and the campaign closed with the capture of Liége by the allies (Oct. 12). Marlborough was created a duke on his return to England in November. He had checked the main enterprise, or at least (for an enterprise commensurate with the force employed had scarcely been imagined) the main army, of the French. Every man in the army knew, moreover, that but for the Dutch deputies the enemy would have been destroyed.

On the Rhine the campaign was, except for two disconnected episodes, quite uneventful. The Imperialists under a methodical general, the margrave Louis of Baden, gathered in the Neckar country and crossed the Rhine above Spire. Catinat, now old and worn out, was sent to Strassburg to oppose the threatened invasion of Alsace, and, like MacMahon in 1870, he dared not assemble his whole force either on the Lauter or on the Ill. The margrave invested Landau (July 29) and with a covering army occupied the lines of the Lauter about Weissenburg, which Catinat did not attack. Hence Landau, valiantly defended by Melac, had to be surrendered on the 12th of September. But at the same time the elector of Bavaria took the side of France, surprised Ulm, and declared a local war on the house of Austria and the "circles" of Swabia and Franconia. The margrave then, in order to defend his own country, prevent the junction of Catinat's forces with the elector, and win back the latter to the Austrian side, recrossed the Rhine and hurried to Kehl with the greater part of his army, leaving a garrison in Landau and a corps of observation on the Lauter. To co-operate with the elector, Catinat had made up a corps out of every available battalion and squadron (keeping for himself not more than a personal escort) and placed it under Lieut.-General Villars. This corps drew away into Upper Alsace and the margrave followed suit until the two armies faced one another on opposite sides of the Rhine near Huningen. But the corps that the elector on his part was to send to meet Villars halted east of the Black Forest, and although, on the 14th of October 1702, after a series of skilful manœuvres, Villars crossed the Rhine and won the first victory of his brilliant career at Friedlingen (opposite Huningen), it was profitless. Soon afterwards Villars placed his army in winter quarters in Alsace, and Louis of Baden disposed his troops in two entrenched camps opposite Breisach and Strassburg respectively. In Italy Vendôme, superior in numbers but handicapped by instructions from Versailles and by the necessity of looking to the Italian interests of King Philip, gained a few minor successes over Eugene. A very hard-fought and indecisive battle took place at Luzzara on the Po on the 15th of August.

Friedlingen.

In the next two years Bavaria was the centre of gravity of the

French operations, and only campaigns of the methodical and non-committal kind were planned for Italy[1] and the Low Countries. Villeroy and Boufflers commanded the French in the Low Countries, Tallard in Lorraine, Villars in Alsace, and Vendôme in Italy.

In the Netherlands the French field army was behind the lines of Brabant, the Spanish troops in the lines of Flanders (Antwerp-Ghent-Aire). Together the two considerably outnumbered Marlborough (90,000 against 50,000), but the duke managed to be first in the field. As early as February Rheinberg had been taken, and in May he followed up this success by the capture of Bonn, returning to the Meuse before Villeroy had assembled his army at Diest. Marlborough's plan was to break the immensely long line of defence of the French and Spaniards by the capture of Antwerp. One Dutch corps under Coehoorn was to assemble in the Sluys-Hulst region, and another under Opdam at Bergen-op-Zoom and Marlborough, after manœuvring Villeroy's field army out of the way, was to join them before the fortress. Marlborough executed his own share of the movement with his usual skill, he pushed back Villeroy towards the Mehaigne and at the right moment, giving them the slip, marched for Antwerp via Hasselt. Villeroy, soon discovering this, hastened thither as fast as possible, and the Dutch generals enabled him to emerge from the manœuvre with a handsome victory, for Coehoorn (in order to fill his own pockets, it has been suggested) had departed on a raid into West Flanders and Opdam was left alone at Eeckeren in front of Antwerp, where Boufflers and the Spanish general Bedmar surprised him (June 30) and put his corps to flight before Marlborough could come to his assistance. In disgust the great captain then resigned himself to a war of small sieges on the Meuse. The campaign closed with the capture of Huy (Aug. 25) and Limbourg (Sept. 27). On the Rhine great projects were entertained by the French, nothing less than the capture of Vienna by a combined Franco-Bavarian-Hungarian army being intended. Villars began by capturing Kehl (March 10) under the very eyes of the margrave, who dared not risk a battle lest the Bavarians coming up in his rear should destroy his weakened army. The Bavarians had in fact no such intention. The elector, while carrying on a trifling war with a small imperial army under Count Styrum, insisted that Villars should cross the Black Forest and join him, which Villars was unwilling to do thus early in the year, as two-thirds of his officers were as usual on leave or detached on recruiting duties. Courtier though he was, the marshal would not stir even in spite of the king's orders until he was ready. At the end of April, leaving Tallard alone to defend Alsace and Lorraine against the margrave, Villars plunged into the defiles of the Black Forest and on the 8th of May joined the elector at Ebingen. All seemed favourable for the advance on Vienna, but at the last moment the elector half repented of his alliance with the enemies of Germany and proposed instead a junction with Vendôme by way of Tirol. This proposal came to nothing, the Tirolese were soon roused to revolt by the misconduct of the ill-disciplined Bavarians, and Vendôme, who, like Luxembourg, was a giant in battle and a sluggard in camp, would not stir. The active Villars meantime was reduced to impotence and faced Styrum in an entrenched camp at Dillingen on the Danube, neither side offering battle.

Villars had posted a protective force at Ulm to contain the margrave's army should it turn back upon him, and this, after an engagement at Munderkingen (July 31) induced the cautious Louis to return to the Rhine. Five weeks later, however, the margrave returned in full force, and moving by the right bank of the Danube reached Augsburg on the 6th of September. The elector, returning from his futile Tirol expedition, had already rejoined Villars at Dillingen, and the marshal persuaded him to attack Styrum before the two imperial generals could join forces. The result was the battle of Hochstett[2] (Sept. 20) in which the elector and Villars won a great victory, at a loss of only 1000 men to Styrum's 11,000. Rarely indeed had an 18th-century general so great an opportunity of finishing a war at one blow. But even Villars saw no better use for the victory than the unimpeded junction of his own army and Tallard's and winter quarters in Württemberg, and the elector on the other hand was principally anxious to evict the margrave's army from his dominions. The question was referred to Versailles, and another month passed away in inactivity. Tallard remained on the Rhine, and Villars in disgust applied to be recalled. The margrave, entrenched as usual, kept the field for another month and then retired to the Lake of Constance, where, in a still unexhausted district, he spent the winter. The elector wintered in the Iller with the combined army. Tallard meanwhile invested Landau and defeated a detachment sent from Marlborough's distant army to relieve the place in the battle of Spire (Nov. 10), which was almost as costly to the allies as Hochstett. Landau surrendered on the 12th of November. Old Breisach, besieged by Vauban, capitulated on the 6th of September. Thus in Germany, though the grand advance on Vienna had come to nothing, the French had won two important victories and established an army in Bavaria. More than this, under the prevailing conditions of warfare, it was impossible to expect. In Italy, on the other hand, Vendôme, although no longer opposed by Eugene, achieved nothing. After a raid towards Trieste he was brought back hurriedly by the news that Victor Amadeus of Savoy had changed sides, and though he was victorious in a few skirmishes and re-established touch with France by capturing Asti, he failed to prevent the Imperialists, under Guido Starhemberg, from slipping past his position in Lombardy and joining the duke of Savoy in Piedmont.

Hochstett, 1703.

The campaign of 1704, though in the Low Countries and in Italy practically nothing was done, is memorable for what was probably the greatest strategical operation in the 18th century, Marlborough's march to the Danube. At the outset the elector and Marsin (Villars' successor) were on the Iller, between Ulm and Memmingen, Tallard between Strassburg and Landau, Villeroy as usual between the Brabant lines and the Meuse. Between Villeroy and Tallard there was a small force on the Moselle, intended to reinforce either. On the other side the Margrave Louis was in the Stockach-Engen region, with his own army and the relic of Styrum's, but being responsible for guarding the whole of the Middle Rhine as well as for opposing the elector he was weak everywhere, and his defence of the Rhine was practically limited to holding the "lines of Stollhofen," a defensive position near Bühl in Baden. With Breisach and Kehl in their own hands, the French were more or less closely in touch with their comrades in Bavaria, and Tallard convoyed a large body of recruits for Marsin's army through the Black Forest defiles. But in doing so he lost most of them by desertion, the margrave's army dogged his march, and in fact no regular line of communication was established. Thus the five armies (Marlborough's, Eugene's, Tallard's, Marsin's and the margrave's) engaged in this theatre of war, were moving and facing in all directions in turn in a most bewildering fashion. Marlborough's purpose at any rate was quite definite—to transfer a large corps from the Low Countries to Bavaria and there in concert with the allies in that quarter to crush the elector decisively. He took no one into his confidence. The timid Dutch were brought, not without difficulty, to assent to a Lower Rhine and Moselle campaign, of much the same sort as the Bonn expedition of 1703, but rather than be burdened with Dutch counsellors he forwent the assistance of the Dutch troops. These were left under Overkirk to defend the Meuse, and English and English-paid troops alone took part in the great venture. Meanwhile Tallard and Marsin, united at the moment of handing over the recruits, had promptly separated again. Tallard, Villeroy and the Versailles strategists,

Rhine and Danube Campaign of 1704.

[1] In this year began the Camisard insurrection, in the Cevennes, which necessitated the detachment of a considerable body of troops from Vendôme's army in Italy. Similarly both in 1702 and 1703 the Hungarian insurrection compelled the Viennese government to keep back the reinforcements of which Eugene stood in need.

[2] Fought on the same battlefield as was Blenheim next year; the latter is consequently called by some the "second battle of Hochstett."

well aware that Marlborough was ascending the Rhine, thought that a diversion on the Moselle was intended, and the feeble warnings of Marsin, who half suspected the real purpose, were disregarded. Villeroy remained in Brabant for fear that Overkirk would take a few towns in his absence.

Marlborough calculated that as he progressed up the Rhine the French would collect to prevent his crossing, instead of themselves passing over to join the elector and Marsin. Thus the expedition would reach the Neckar mouth, without its true purpose being suspected, and once there Marlborough would vanish from the ken of the defenders of the Rhine, to reappear on the Danube where he was least expected. On the 12th of May the army crossed the Meuse at Ruremond, on the 23rd it reached Bonn, on the 29th Mainz. On the 1st of June the puzzled French noted preparations for bridging the Rhine at Philipsburg. But two days later the English had turned to their left into the valley of the Neckar. On the 10th of June Prince Eugene and on the 13th the margrave appeared at the duke's headquarters to concert operations. It was arranged that the margrave was to join Marlborough and that Eugene should command the Stollhofen and other forces on the Rhine, for Tallard, it seemed, was about to be joined by Villeroy[1] and Marlborough knew that these marshals must be kept west of the Rhine for the six weeks he allowed himself for the Bavarian enterprise. The margrave's army duly joined Marlborough's on the 22nd of June at Ursprung, 12 m. north of Ulm, where the elector and Marsin were encamped. The endurance of Marlborough's corps, as displayed in the long march from Ruremond, was not the least extraordinary feature of the operation. For 18th-century troops such performances were generally provocative of desertion, and involved the ruin of the army that attempted it. But Prince Eugene, we are told, was astonished at the fine condition of the army. On the French side meantime all was perplexity, and it was not until a week after the margrave and Marlborough had united that a decision was arrived at by Louis XIV., in whose eyes the feeble corps of Eugene sheltered in the lines of Stollhofen constituted a grave menace for Alsace and Lorraine. Villeroy's main body from the Meuse had after its first hesitations followed up Marlborough, in readiness for the supposed Rhine and Moselle campaign, and was now about Landau. Tallard with the smaller half of the united armies was to advance by Breisach and to "try to capture Villingen." Villeroy was to watch Eugene's corps, or rather the Stollhofen-Bühl position, and the small Moselle corps was to remain west of the Rhine. This meant conceding both the initiative and the superiority in numbers to Marlborough.

Marlborough's March to the Danube.

The duke had now manœuvred himself with brilliant success from one theatre of war to another, and had secured every advantage to himself. His method of utilizing the advantage showed his mastery of the rules of the strict game that, with the instinct of a great captain, he had just set at nought. From before Ulm he sidled gradually along the north side of the Danube in the hope of finding an unguarded passage. He and the margrave exercised the general command on alternate days, and when on his own day he arrived opposite Donauwörth, knowing Louis's caution, he thought that direct attack was better than another two days' extension to the east. Moreover he needed a walled town to serve as a magazine instead of Nördlingen, which he had used of late but which could not serve him for operations over the river. In the late afternoon of the 21st the army was flung, regardless of losses, against the entrenched hill of the Schellenberg at Donauwörth, where the elector had posted a strong detachment. The attack cost 6000 men, but it was successful, and of the 12,000 Bavarians on the hill only 3000 returned to their main body, which had now moved from Ulm to Lauingen. Passing the river, the allies besieged and took the small fortress of Rain, and thence moved to the neighbourhood of Augsburg, thoroughly and deliberately devastating the countryside so as to force the elector to make terms. The best that can be said of this barbarous device, more or less legitimate in the days when the quarrel was the people's as much as the prince's, is that Louis XIV. had several times practised it. Its most effective condemnation is that military devastations, in these purely political contests, were entirely unprofitable. Louis had already found them so, and had given up the practice. In the present case the acts of the allies only confirmed the elector in his French sympathies, while at the same time Marlborough's own supplies ran short, his convoys were harassed and his reconnaissances impeded. The movements of the two armies were but trifling. Marlborough, though superior, was not decisively superior, and his opponents, well entrenched near Augsburg, waited for Tallard and (in vain) for Villeroy. Marlborough marked time until Eugene should join him.

Campaign on the Danube, 1704.

There were now five armies in the field, two allied and three French. The centre of gravity was therefore in Villeroy's camp. If that marshal followed Tallard, even Eugene's junction with Marlborough would not give the latter enough force. If Tallard alone joined the elector and Eugene Marlborough, the game was in the hands of the allies. But none of the possible combinations of two armies against one were attempted by either side. Eugene did not venture to leave Villeroy's front to attack Tallard, who was marching by Kehl-Villingen-Ulm on Augsburg, but when he knew that Tallard was on the move he slipped away from Villeroy to join Marlborough. In turn, Tallard and the elector, aware of Eugene's march, could have left Marlborough to his sieges and combined against Eugene, but they were well content to join forces peaceably at Augsburg. Worst of all, Villeroy, in whose hands was the key of the situation, was the nearest to Versailles and the least capable of solving the knotty problem for himself. When the king bade him follow Tallard to Villingen he hesitated, and when he had made up his mind to try, Louis had changed his and ordered him to detain Eugene (who was already far away) in the Stollhofen lines. The last stage of the campaign was brief. Marlborough and Eugene had in mind a battle, Tallard and Marsin a war of manœuvre to occupy the few weeks now to be spun out before winter quarters were due. The two allied armies met in the Danube valley on the 6th of August. If the enemy remained on the south side Eugene was to cross, if they recrossed to the north bank Marlborough was to follow suit. The margrave Louis of Baden had been sent off to besiege Ingolstadt as soon as Eugene had come within a safe distance. The 18th-century general relied far more on himself than on the small surplus of force that his army, in the conditions of that time, could hope to have over its opponent. When therefore the French and Bavarians were reported opposite Eugene on the north side, Marlborough crossed at once, and without waiting for the margrave the two great soldiers went forward. On the 2nd of August (see BLENHEIM) they attacked and practically destroyed the armies of Tallard, Marsin and the elector.

The campaign of 1705 was uneventful and of little profit to either side. Marlborough's army had returned to the Low Countries, engaging *en route* in a small campaign in the Luxemburg and Thionville region, which was defended with skill and success by Villars. Villeroy had also returned to Brabant and retaken Huy. With him was the now exiled elector of Bavaria. On the 18th of July, after a series of skilful manœuvres, Marlborough forced the lines of Brabant at Elissem near Tirlemont, but not even the glory of Blenheim could induce the Dutch deputies to give him a free hand or the Dutch generals to fall in with his schemes. King Louis was thus able to reinforce Villeroy betimes from Villars's Lorraine army, and the campaign closed with no better work than the razing of the captured French entrenchments. On the Rhine Villars, with a force reduced to impotence by the losses of Blenheim and the detachments sent to Villeroy, carried on a spiritless campaign about Hagenau and Weissenburg against the margrave Louis. In Italy alone was there any serious encounter. Here Vendôme's army and a fresh corps from France were engaged in the attempt to subdue Victor Amadeus and his new Austrian allies (Starhemberg's, originally Eugene's army), and they were

Campaign of 1705.

[1] Even Villeroy it appears rose to the situation thus far, but the king only allowed him to send 25,000 men to Tallard.

so far successful that the duke implored the emperor to send a fresh army. Eugene commanded this army, opposed to which was a force under Vendôme's brother Philippe, called the Grand Prior. This man, a lazy dilettante, let himself be surprised by Eugene's fierce attack on the line of the Adda. The day was restored however, and the Austrians beaten off, thanks to Vendôme's opportune arrival and dauntless courage (battle of Cassano, August 16). Nevertheless, the subjugation of Piedmont was put off until next year, by Louis's orders.

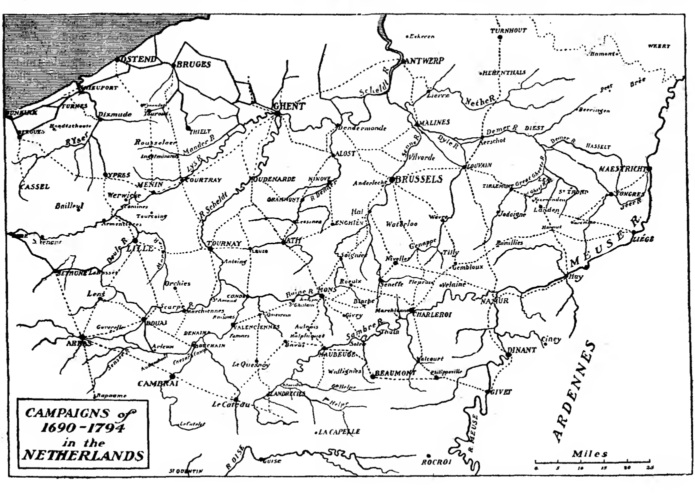
1706 was a bad year for the French. At the very outset of the campaign in the Netherlands, Villeroy, hearing that some of the allied contingents that composed Marlborough's army had refused to join, went forward from his new defensive lines along the Dyle and offered battle. Marlborough would probably have fought in any case, but being joined in time by the belated allied contingents, he was able (May 12) not only to win but also to profit by the glorious victory of Ramillies (*q.v.*) on the 12th of May. This was one of the few cases of thoroughly efficient and successful pursuit in the military history of the 17th and 18th centuries. The whole of Flanders and Brabant, except a few minor fortresses, fell into his hands within two weeks. These too fell one after the other in August and September, and the British cavalry crossed the French frontier itself. But on the Rhine the inactivity of Louis of Baden had allowed Villars to transfer the bulk of his army to the Netherlands. Vendôme, too, was sent to succeed Villeroy, and Marlborough made no further advance. Louis's two most brilliant commanders devoted themselves to organizing the defence of the French frontier, and did not venture to interrupt Marlborough's sieges.

Ramillies, 1706.

In Italy the campaign had, as before, two branches, the contest for Piedmont and the contest between the French forces in Lombardy and the Austrian second army that sought to join Victor Amadeus and Starhemberg. The latter, repulsed by Vendôme at Cassano, had retired to Brescia and Lake Garda, Vendôme following up and wintering about Castiglione and Mantua, and in April 1706, profiting by Eugene's temporary absence, Vendôme attacked the Imperialists' camp of Montechiaro-Calcinato. His intention was by a night march to surprise the post of Ponte San Marco on their extreme left, but when day came he noticed that he could give battle to the enemy's left wing at Calcinato before their right from Montechiaro could intervene. His onset broke up the defence completely (battle of Calcinato, April 19), and he hustled the fragments of the Imperialist army back into the mountains, where Eugene had the greatest difficulty in rallying them. Until the middle of June Vendôme completely baffled all attempts of Eugene to slip past him into Piedmont. He was then, however, recalled to supersede Villeroy in Belgium, and his feeble successors entirely failed to rise to the occasion. Philip of Orleans, with Marsin and the duc de la Feuillade as his advisers, was besieging Turin, trying in vain to remedy the errors of the engineers and the constant repulse of small storming parties by a savage bombardment of the town itself. As soon as he knew of Vendôme's departure Prince Eugene emerged afresh from the mountains, and, outmanœuvring the French in Lombardy without the least difficulty, hurried towards Turin. Victor Amadeus, leaving the defence to the Austrian and Piedmontese infantry, escaped through the besiegers' lines and joined his cousin with a large force of cavalry. On the 7th of September they attacked the French lines round Turin. Owing to the disagreements of their generals, the various corps of the defenders, though superior in total numbers, were beaten in detail by the well-concerted attacks of Eugene, Victor Amadeus and the Turin garrison. Marsin was killed, many of the boldest officers in the army lost heart, and Philip retreated ignominiously to Pinerolo. Although in the same week Lieut.-General Médavy-Grancey inflicted a severe defeat on

Calcinato.

Battle of Turin.



the Austrians who were still left in Lombardy (Castiglione, Sept. 9) the battle of Turin practically ended the war in Italy.

Both in the north and in the south the tide had now receded to the frontiers of France itself. Louis could now hope to gain the objects of the war only partially and by sheer endurance. But it is from this very point that the French operations cease (though only gradually it is true) to be the ill-defined and badly-joined patchwork of forays and cordons that they had hitherto been. In the place of Tallards, Marsins and Villeroys Louis made up his mind to put his Villars, Vendômes and Berwicks, and above all the approach of the allied armies roused in the French nation itself a spirit of national defence which bears at least a faint resemblance to the great uprisings of 1792 and 1870, and under the prevailing dynastic and professional conditions of warfare was indeed a startling phenomenon. For the gathering of this unexpected moral force 1707 afforded a year of respite. The emperor, desiring to occupy Naples and Lombardy with the least possible trouble, agreed to permit Médavy-Grancey to bring off all the Italian garrisons, and with these and the militia battalions of the Midi Marshal Tessé formed a strong army for the defence of the Alpine frontier. In Spain the campaign opened with the brilliant success of Berwick at Almanza. In Germany Villars not only pricked the bubble reputation of the lines of Stollhofen,[1] but raided into Bavaria, penetrating as far as Blenheim battlefield before he gave up the attempt to rouse the Bavarians again. The Imperialists and Piedmontese in the south succeeded in turning the Alpine barrier, but they were brought to a complete standstill by Tessé's gallant defence of Toulon (August) and having, like their predecessors in 1692, roused the peasantry against them they retired over the mountains. In Belgium the elector of Bavaria, who was viceroy there for King Philip, and was seconded by Vendôme, remained quiescent about Mons and Gembloux, while Marlborough, paralysed more completely than ever before by the Dutch, spent the summer inactive in camp on the Gheete.

Changing Conditions of the War.

The respite of 1707 had enabled Louis to gather his strength in Flanders. Henceforward operations on the Rhine and in Dauphiné are of quite secondary importance, so much so that Eugene and the main Austrian army are always found in the Low Countries fighting side by side with the Anglo-allied army of Marlborough.

In 1708 Eugene foresaw this shift of the centre of gravity and arranged with Marlborough to transfer the army which was ostensibly destined for the Rhine campaign to Brabant, repaying thus the debt of 1704. Indeed the main army of the French was markedly superior in numbers to Marlborough's and hardly inferior to Marlborough's and Eugene's combined. Placing the elector of Bavaria, with Berwick to advise him, at the head of the small army of Alsace, he put his young grandson and heir, the duke of Burgundy, at the head of the great army which assembled at Valenciennes, and gave him Vendôme as mentor. But the prince was pious, mild-mannered, unambitious of military glory and also obstinate, and to unite him with the fiery, loose-living and daring Vendôme, was, as Saint-Simon says, "mixing fire and water." At the end of May operations began. Vendôme advanced to engage Marlborough before Eugene, whose purpose had become known, should join him. As the French came on towards Brussels, Marlborough, who had concentrated at Hal, fell back by a forced march to Louvain. Vendôme having thus won the first move, there was a pause and then the French suddenly swung round to the west, and began to overrun Flanders, where their agents had already won over many of the officials who had been installed by the allies since 1706. Ghent and Bruges surrendered at once, and to regain for King Philip all the country west of the Scheldt it only remained to take Oudenarde. On the day of the surrender of Ghent Marlborough was in pursuit, and one long forced march brought his army almost within striking distance of the receding enemy. But though Eugene himself had joined him, Eugene's army was still far behind, and the duke was stopped by demands for protection from the officials of Brussels. Vendôme soon moved on Oudenarde. But scarcely had he begun this investment when Marlborough was upon him. The duke discussed the situation with Eugene, who had placed himself under his friend's orders. Marlborough was half inclined—another general would have been resolved—to wait for Eugene's troops before giving battle, for he knew that Vendôme was no ordinary opponent, but Eugene counselled immediate action lest the French should escape, and relying on his own skill and on the well-known disunion in the French headquarters, Marlborough went forward. As he approached, the French gave up the siege of Oudenarde and took up a position at Gavre, 7 m. lower down the Scheldt, so as to be able to act towards either Ghent or Oudenarde. Marlborough's advanced guard, boldly handled by Cadogan, slipped in between Gavre and Oudenarde. At once the dissensions in the French headquarters became flagrant. Vendôme began to place part of the army in position along the river while the duke of Burgundy was posting the rest much farther back as another line of defence. Cadogan was thus able to destroy the few isolated troops on the river. Thereupon Vendôme proposed to the duke to advance and to destroy Cadogan before the main body of the allies came up, but the young prince's hesitations allowed the chance to pass. He then proposed a retreat on Ghent. "It is too late," replied Vendôme, and formed up the army for battle as best he could. The allied main body, marching with all speed, crossed the Scheldt at all hazards and joined Cadogan. In the encounter-battle which followed (see Oudenarde) Marlborough separated, cut off and destroyed the French right wing. The French retreated in disorder on Ghent (July 11) with a loss of 15,000 men. Nevertheless Oudenarde was in no way decisive, and for the rest of the campaign the two armies wandered to and fro in the usual way. Berwick, recalled from Alsace, manœuvred about Douay, while Vendôme remained near Ghent, and between them Marlborough's and Eugene's armies devoted themselves to the siege of Lille. In this town, one of Vauban's masterpieces of fortification, the old Marshal Boufflers had undertaken the defence, and it offered a long and unusually gallant resistance to Eugene's army. Marlborough covered the siege. Vendôme manœuvred gradually round and joined Berwick, but though 90,000 and later 120,000 strong, they did not attack him. Berwick was a new element of dissension in the distracted headquarters, and they limited their efforts first to attempting to intercept a hugh convoy of artillery and stores that the allies brought up from Brussels for the siege,[2] and secondly to destroy another convoy that was brought up from Ostend by the General Webb known to readers of *Esmond*. The futile attack upon the second convoy is known as the action of Wynendael (Sept. 28). The only other incident of the campaign in the open was an unsuccessful raid on Brussels by a small corps under the elector of Bavaria from the Moselle via Namur.

Campaign of 1708.

Oudenarde.

Siege of Lille.

On the 8th of December the brave old marshal surrendered, Eugene complimenting him by allowing him to dictate the terms of capitulation. Ghent and Bruges were retaken by the allies without difficulty, and, to add to the disasters of Oudenarde and Lille, a terrible winter almost completed the ruin of France. In despair Louis negotiated for peace, but the coalition offered such humiliating terms that not only the king, but—what in the 18th century was a rare and memorable thing—his people also, resolved to fight to the end. The ruinous winter gave force to the spirit of defence, for fear of starvation, inducing something akin to the courage of despair, brought tens of thousands of recruits to the colours.

Of the three invasions of France attempted in this memorable year two were insignificant. On the Rhine the elector of

[1] The Margrave Louis of Baden had died during the winter of 1706–1707. He was succeeded by the incompetent margrave of Bayreuth, who was soon displaced. This general's successor was the elector of Hanover, afterwards King George I. of England.

[2] An excellent illustration of 18th century views on war is afforded by the fact that the completely successful defence of this convoy was regarded by his contemporaries as Marlborough's greatest triumph.

Hanover (King George I.) was held in check by the duc d'Harcourt on the Lauter and finally retired to the lines of Stollhofen, while a smaller allied corps under the imperialist general Count Mercy was defeated with heavy loss by Harcourt's second in command, Du Bourg, at Rumersheim in Upper Alsace (Aug. 26). On the Alpine frontier Berwick, abandoning the fashionable method of "lines," prepared a remarkable system of mobile defence pivoted on Briançon, on which Victor Amadeus's feeble attacks made no impression. These affairs were little more than diversions. The main, indeed the only, attack was Marlborough's and Eugene's, and the Malplaquet campaign is one of the few episodes of 18th century warfare that retain a living and passionate interest.

Campaign of 1709.

Long before this Marlborough had proposed to dash straight forward into France, masking the fortresses, but this scheme was too bold even for Eugene, who preferred to reduce the strong places before going on. Lille having been successfully besieged, Tournai was the next objective, and—while Villars and his lieutenants Montesquiou and Albergotti lay inactive in their entrenchments at Béthune, Douai and Denain on the Scheldt, training their thousands of recruits and suffering severely from the famine that followed upon this bad winter—the allies suddenly and secretly left their camps before Lille as if for an attack on the Douai lines (June 26–27). But before noon on the 27th they had invested Tournai. A few days afterwards their siege guns came up from Menin by water (down the Lys and up the Scheldt) and the siege was pressed with intense vigour. But it was the 3rd of September before the citadel capitulated. Then Marlborough, free to move again, transferred his army secretly and by degrees to the river Haine, beyond Villars's right. East of St Ghislain Villars's long lines of earthworks were but thinly held, and after a march of 50 m. in 56 hours through rain-sodden country, the allied advanced guard passed through them unopposed (Sept. 6th). Mons, too, was weakly held, and Marlborough hoped by the rapidity of his operations to take it before Villars could interrupt him. Based on Mons and Brussels, he could then, leaving the maze of fortresses in the Arras-Valenciennes region to his right, push on (as eighty years afterwards Coburg attempted to push on) straight to the heart of France. But Villars also moved quickly, and his eager army was roused to enthusiasm by the arrival of Marshal Boufflers, who, senior as he was to Villars, had come forward again at the moment of danger to serve as his second in command. Thinking that the allies were somewhat farther to the east than they were in fact, the French marshal marched secretly, screened by the broken and wooded ground to the south of the fortress, and occupied the gap of Aulnois-Malplaquet (Sept. 9), one of the two[1] practicable passages, where he set to work feverishly to entrench himself. Marlborough at once realized what had happened, and giving up the siege of Mons brought his army to the south-east of the place. Preparing, as at Oudenarde, to attack as rapidly as his brigades came on the scene, he cannonaded the French working parties and drew the return fire of all Villars's guns. At this crisis the duke submitted the question of battle—unwillingly, as one may imagine—to a council of war, and Eugene himself was opposed to fighting an improvised battle when so much was at stake. Others thought the capture of the little fortress of St Ghislain was the best solution of the problem, and it was not until the 11th that the allies delivered their attack on the now thoroughly entrenched position of the French. The battle of Malplaquet (*q.v.*) was by far the most desperately contested of the war. In the end Boufflers, who took command when Villars was wounded, acknowledged defeat and drew off in good order, the left to Valenciennes, the right to Bavay and Le Quesnoy. Eugene was wounded, and Marlborough, after the most terrible experience in any soldier's lifetime, had only enough energy remaining to take Mons before he retired into winter quarters. The loss of the French is given variously as 7000 and 12,000. The allies sacrificed no less, probably more, than 20,000 men, and if the English and Austrian survivors could count themselves the bravest soldiers alive, one considerable part of the allied army at least, the Dutch contingent, was ruined for ever. Even at Fontenoy, thirty-six years later, the memory of Malplaquet made them faint-hearted. From his bed the wounded Villars wrote triumphantly to Louis: "If God gives us another defeat like this, your majesty's enemies will be destroyed."

Malplaquet.

[1] The other, scarcely less celebrated, is that of Jemappes.

In 1710 Villars lay entrenched behind a new series of lines, which he called *Ne plus ultra* and which extended from Valenciennes to the sea. Marlborough made no attempt to invade France from the side of Mons, for Villars at the head of the army which had been through the ordeal of Malplaquet was too terrible an opponent to pass by with impunity. In England, too, the anti-Marlborough party was gaining the upper hand in the queen's council. So Marlborough took no risks, and returning to the Lille side, captured Douai (June 26) and Béthune (Aug. 26). No attack was attempted upon the lines. In Dauphiné, Berwick again repulsed the Austrians and Piedmontese.

Campaign of 1710.

1711 was Marlborough's last campaign, and it was remarkable for the capture of the *Ne plus ultra* lines by manœuvres that must be recorded as being the *ne plus ultra* of the 18th-century way of making war by stratagem. In May the sudden death of the emperor completely altered the political outlook, for his successor Charles was the coalition's claimant to the throne of Spain, and those who were fighting for the "balance of power" could no more tolerate a new Charles V. than they could see Louis XIV. become a Charlemagne. Before the allies could agree upon any concerted action, Eugene's army had departed for Germany, and Marlborough alone was left to face Villars's great army. But in pursuance of the policy of passive endurance the marshal remained on the defensive behind the lines, and Marlborough determined to dislodge him. What force could not achieve, the duke trusted to obtain by ruse. The lines extended from the sea along the Canche, thence to Arras, and along the Sensée to Bouchain on the Scheldt. Marlborough held Lille, Tournai, Béthune and, in front of these places, Douai, while Villars's strong places, other than those in the lines, were Valenciennes, Condé, Le Quesnoy, &c. As the western part of the lines, besides being strong, were worthless from the invaders' point of view because their capture could not lead to anything, Marlborough determined to pass the barrier between Arras and Bouchain. Here the front was difficult of access, because of the inundations and swamps of the Sensée valley, but two causeways crossed this valley at Arleux and Aubanchoeil-au-Bac respectively. On the 6th of July Marlborough, who had encamped in the plain of Lens, sent a detachment to capture Arleux. He then marched away to the west as if to attack the lines between Arras and the headwaters of the Canche. Villars followed suit, but left a corps behind, as Marlborough had expected and desired, to retake Arleux. The commander of the garrison then sent urgent messages to say that he could not hold out, and Marlborough sent off Cadogan to relieve him. Cadogan, the only officer in the army in the duke's confidence, moved slowly, and the garrison had to surrender (July 22). Villars razed the defences of Arleux. The plot of the comedy now thickened. Marlborough lost his usual serenity, and behaved in so eccentric a manner that his own army thought him mad. He sent off one part of his forces to Béthune, another back to Douai, and ordered the small remainder to attack the lines between the Canche and Arras, where, as every one knew, Villars's whole army was massed. On the 24th of August he personally reconnoitred the lines with a large staff, and calmly gave his generals instructions for the lines to be stormed. But Cadogan was hastening to give the duke's real orders to the corps at Béthune and Douai. In the night of the 4th-5th of August the main army set out for Aubanchoeil-au-Bac, at the highest possible speed. The Scarpe was crossed, the Béthune column came in punctually, and the word was passed down the ranks that Cadogan had crossed the lines at Arleux. Thereupon the pace was increased, though thousands of the infantry fell out and scores died from exhaustion. Five hours ahead of the French

The Ne Plus Ultra Lines.

Marlborough's Manœuvre.

army and level in the race with Villars and the cavalry, the red-coats crossed the rivers at Arleux, while Marlborough and the horse hurried on to Aubanchoeil-au-Bac, crossed there and turned back along the Sensée to meet the French squadrons. The army reassembled between Aubanchoeil-au-Bac and Cambrai, and its leader, declining Villars's offer of a battle in front of Cambrai, manœuvred still farther to the east and invested Bouchain. The siege, covered by a strong " line of circumvallation " which Villars did not attempt to attack, ended with the surrender of the place on the 13th of September, and so terminated a series of manœuvres which to the modern mind is so extraordinary as to be almost incredible. In December of this year, his party opponents in England being now triumphant, the man who was so consummate a master both of the 18th-century and the Ramillies-Oudenarde methods of making war was dismissed the service in disgrace. In June 1712 the British contingent, under the duke of Ormonde, withdrew from the Low Countries, the discontent of the men at Marlborough's disgrace breaking out in open mutiny, and thus ignominiously ended the career of the army of Blenheim and Malplaquet. The coalition practically dissolved.

But Holland and Austria determined to make one last effort to impose their own terms on Louis. Eugene's army, which had been used in 1711 to influence the imperial election instead of to beat Villars, was brought back to the Low Countries. Reading the meaning of Marlborough's fall, he quietly made preparations to take over the various allied contingents into Imperial or Dutch pay. Thus when England seceded, Ormonde only marched away with some 12,000 sullen men, and over 100,000 remained with the prince.

Misfortunes at Versailles helped Eugene in his first operations, for three members of Louis's family died within a week and all was in confusion, not to speak of the terrible misery that prevailed in the country. But the old king's courage rose with the danger and he told Villars that if the army were beaten he would himself join it and share in its fate. Villars, though suffering still from his Malplaquet wound, took command on the 20th of April, and spun out time on the defensive until the end of May, when Ormonde's contingent withdrew. Eugene, apparently with the intention of regaining the Mons line of operations, as the defection of England had made further operations near the sea unprofitable, neglected to besiege, not only Arras, but Valenciennes and Condé as well, and, based temporarily on Douai and Marchiennes and Bouchain he took Le Quesnoy (July 4) and moved thence on to Landrecies, which was closely invested. Then followed the last serious fight of the war, the battle of Denain, which saved the French monarch and completed the disintegration of the coalition.

In order to protect his camps around Landrecies, Prince Eugene constructed the usual lines of circumvallation with such speed that Villars, on coming up, found that they were too formidable to attack. Next, in order to guard the movements of his convoys between Marchiennes-on-Scarpe and the front against attacks from Cambrai or Valenciennes, he hedged in the route on both sides with continuous lines of breastworks, to the defence of which he assigned his Dutch corps. Villars anxiously looked out for an opportunity of breaking these modern " long walls." At Denain, the besiegers' route crossed the Scheldt. From this point to the front, streams and other

Denain.

obstacles reinforced the defence, but the marshal was told by a country priest that the lines were assailable north of Denain, and resolved to attack them there. The enterprise, like Marlborough's forcing of the *Ne plus ultra* lines, involved an extraordinary combination of resolution and skill—*i.e.* force and fraud—for the point of attack was far away and the opposing army almost within cannon-shot. Some days were spent by Villars in deceiving Eugene and his own army as well, as to his real intentions, and by various feints Eugene was induced to mass his main body about Landrecies and Le Quesnoy on the south side of the Scheldt. Then on the night of the 23rd of July the French army moved off silently, with its bridging train in the vanguard and cavalry posted everywhere along its right flank to conceal the march. By 9 a.m. on the 24th Villars's army had completely deployed on the north bank of the Scheldt. Eugene himself saw them and galloped away to bring up his army from Landrecies. But, long before it arrived, Villars's troops, without wasting precious moments in formal preparations, stormed the lines. The Dutch—spiritless since Malplaquet—were huddled into the narrow avenue between the two entrenchments and forced back on Denain. Their generals were taken. The broken mob of fugitives proved too heavy a load for the bridges at Denain, and many were drowned, while the rest, pinned against the bank of the now impassable river, tamely surrendered. Eugene arrived on the other bank with some brigades of the imperial infantry, but after losing heavily gave up the attempt to reopen the passage. Villars followed up his victory at once. Montesquiou captured Marchiennes and Albergotti St Amand, and in these places all Eugene's reserve stores, pontoons and guns fell into the hands of the French. On the 2nd of August Eugene broke up the siege of Landrecies and retreated by a roundabout route to Mons, while Villars's lieutenants retook Douai and Bouchain (September–October). Before the next campaign opened the treaty of Utrecht had been signed, and although the emperor continued the struggle alone for another year, the enfeebled combatants were content to accept Villars's captures of Landau (July 22, 1713) and Freiburg (Nov. 21) as decisive. The treaty of Rastatt, between Austria and France, was signed on the 7th of March 1714, Eugene and Villars being the negotiators.

Naval Operations, and Military Operations in Spain

The war of the Spanish succession affected all the nations of western, northern and central Europe in a greater or less degree, but that part of it which was fought out on the soil of Spain lay aside from the campaigns in Flanders, Germany and Italy. The purely Spanish campaigns had a close connexion with the movements of the fleets, and the two may be conveniently taken together. The naval war was superficially somewhat wanting in interest. Louis XIV., having to support armies of unprecedented size to contend with the forces of the Grand Alliance, and having also to meet the immense cost of the support of his court and the construction of palaces, was compelled to neglect his navy. Except therefore in 1704 he made no attempt to oppose the fleets of the allies with equal forces at sea. The honour of the French flag was chiefly maintained by the privateers who showed high courage and much skill. Some of their enterprises were undertaken with well-appointed squadrons, and attained to the dignity of regular operations of war.

When the Grand Alliance was formed on the 7th of September 1701 a French naval force under M. de Chateaurenault was in the West Indies. Its avowed purpose was to cover the arrival in Europe of the Spanish treasure ships. The secret intention of King Louis XIV. was that the treasure should be brought into a French port, and used by him for the general advantage of the house of Bourbon. On the 12th of September a British squadron of 10 ships commanded by Admiral Benbow was sent to the West Indies to intercept Chateaurenault, and carry out other attacks on the French and Spaniards. Benbow, who was reinforced in the West Indies, did not intercept Chateaurenault, and his cruise was rendered of no effect by the gross misconduct of most of his captains, who refused to support him in an action with a French squadron under M. Du Casse near St Martha on the 20th of August 1702 and subsequent days. He was himself mortally wounded, but lived long enough to bring his captains to court martial. Two of them were shot for cowardice. The treasure fleet sailed for Europe only to fall into the hands of the allies at Vigo. On the 1st of July 1702 a powerful combined fleet of 30 British sail-of-the-line under Sir George Rooke, and

20 Dutch under Admiral Allemonde sailed from Spithead carrying 5000 troops. The general command was given to the duke of Ormonde. The purpose of this expedition was to occupy Cadiz and encourage a rising in Andalusia on behalf of the Habsburg candidate. It reached Cadiz on the 22nd of August, but the inhabitants and the garrison remained loyal. The leaders of the expedition quarrelled with one another and the soldiers aroused the bitter indignation of the inhabitants by plundering the small towns of Santa Maria and Rota. On the 30th of September the expedition sailed away. Information sent by the British minister at Lisbon that Chateaurenault had put into Vigo reached them at Lagos. The duke of Ormonde and his colleagues decided to attack the treasure fleet. On the 22nd of October they forced the boom laid by the enemy between the inner and outer harbours of Vigo, and the treasure fleet was destroyed, but the bullion had been landed.

During 1703 the "grand fleet" of the allies, *i.e.* their main force in European waters, entered the Mediterranean to carry help to the insurgent Protestants in the Cevennes, but effected nothing of importance. Portugal having now joined the Alliance, it was decided to make a serious effort in Spain. A combined fleet carrying 4000 Dutch and 8000 British troops, and conveying the archduke Charles, claimant of the Spanish throne, sailed from Spithead on the 11th of February 1704. Portugal undertook to provide 30,000 troops to co-operate with the British and Dutch who were landed at Lisbon on the 8th of March. The operations on land were for the most part languid. The duke of Berwick who commanded the Bourbon forces on the Spanish frontier formed a vigorous plan for the invasion of Portugal. One Spanish force under Don Francisco Ronquillo was to threaten Beira Alta at Almeida. He himself entered Beira Baixa by the north bank of the Tagus. The prince of Tzerclaes was to have advanced from the south to meet Berwick at Villa Velha. But though Berwick achieved some success, and though both the Dutch general Fagel who operated on the north of the Tagus, and the British general, the duke of Schomberg, who was stationed on the south, proved indolent and incapable, the invasion failed. Ronquillo and Tzerclaes failed to support Berwick, and the newly levied Spanish troops proved unsteady. Fagel was surprised and taken prisoner with 2000 men at Sobreira Fermosa, and some of the frontier posts remained in Berwick's hands when the heat from which the British and Dutch soldiers suffered severely suspended operations. At sea, however, a material success was gained. Sir George Rooke went on from Lisbon accompanied by Prince George of Hesse-Darmstadt, to Barcelona. The prince who had been governor of Catalonia, believed that he could bring about a rising in the province in favour of the Habsburg cause. As the fleet carried no considerable body of troops, Rooke and Hesse-Darmstadt failed to persuade the Catalans to act. They were embarrassed by the knowledge that the count of Toulouse, a natural son of Louis XIV., the admiral of France, who had sailed from Brest on the 6th of May with 23 sail-of-the-line had entered the Mediterranean, and had reached Toulon in June. In expectation of an attack by the united fleets of Brest and Toulon, the allies fell back to the straits. Having obtained information that Gibraltar (*q.v.*) was not sufficiently garrisoned, they attacked and took it on the 3rd of August. On the 24th the count of Toulouse, came to the relief of the fortress with 50 sail-of-the-line, and 24 galleys. He engaged the allies, 62 British and Dutch line of battleships in all, off Malaga. The engagement was a cannonade accompanied with great loss of life, but without manœuvring on either side. The French retired to Toulon, and the allies remained in possession of Gibraltar. An attempt of the Spaniards to retake it, made at the end of 1704 and beginning of 1705 was baffled by the resolute defence of the prince of Hesse-Darmstadt, and the relief afforded to the garrison by the squadron of Sir John Leake, who was left on the coast of Portugal, when Sir George Rooke returned to England.

The events of 1704 had persuaded the allies to make more serious efforts to push the war in Spain. The duke of Schomberg was removed from the command of the troops in Portugal and replaced by the earl of Galway, a French Huguenot exile. But the main attack was made, and the first successes were achieved on the east coast of Spain. On the 3rd of June 1705 Charles Mordaunt, earl of Peterborough, was sent with a commission to command both the fleet and the army, and to promote a rising in favour of the Habsburg, or Austrian party. He was joined by the archduke at Lisbon, and by the prince of Hesse-Darmstadt at Gibraltar. The truth in regard to the operations which followed has been very much obscured. Peterborough, a man of much erratic cleverness, but vain, spiteful and absolutely indifferent to truth, successfully represented himself as a species of hero of romance who won the most astonishing victories in spite of want of means, and of the ill will or incapacity of his colleagues. Critical investigation has destroyed much of the showy edifice of fiction he contrived to erect. The substantial facts are that after some operations on the coast of Valencia, which led to an insurrectionary movement in favour of the archduke, Barcelona was attacked and taken between the 13th of September and the 9th of October. The prince of Hesse-Darmstadt was killed during the siege.

All the east of Spain, the former kingdom of Aragon, which was at all times restive under the supremacy of Castile, now pronounced more or less openly for the Austrian party. The fall of Barcelona gave a severe shock to the Bourbon king. He came in person with Marshal Tessé who had replaced the duke of Berwick, and endeavoured to retake the town early in April 1706. The brutality with which Tessé treated the people of Aragon and Catalonia raised the country against the Bourbon king. The British relieved Barcelona on the 9th of May, and Philip V. was compelled to retreat across the Pyrenees to Perpignan. In the meantime the withdrawal of troops from the Portuguese frontier for service in Catalonia, had opened the way for an invasion of Castile by the allies, British, Portuguese and Dutch. They occupied Madrid on the 25th of June 1706, and the queen who acted as regent in the absence of her husband retired to Burgos. But the success of the allies was merely apparent. The appearance in their midst of an invading army of Portuguese and heretics roused the national feeling of the Castilians. They rallied to the Bourbon cause. As in the later Peninsular War, guerrillero bands sprang up on all sides, and they found capable leaders in Vallejo and Bracamonte. The duke of Berwick, who was sent back to Spain, collected an army, and soon the allies, who were distressed by want of provisions and bad health, were forced to evacuate Madrid. They moved on Guadalajara to meet the archduke who was advancing from the east. Berwick outmanœuvred them, and forced them to retreat on Valencia. In February 1707 they were reinforced by troops brought by the fleet and advanced in April. On the 25th of the month they were defeated by the French and Spanish troops at Almansa in the province of Alicante, with the loss of all their infantry.

From this date till 1710, the land war in Spain remained stationary. The Bourbon king was master of the greater part of Spain, including Aragon. His generals retook Lérida on the Catalan frontier, and on the Portuguese frontier at La Gudiña near Badajoz, on the 7th of May 1709, a Spanish army under the Marques de Bay defeated an Anglo-Portuguese army under the earl of Galway. Yet the Austrian party held Catalonia and Valencia, and the financial distress of the Spanish government, aided by the disorganized state of the administration, rendered a vigorous offensive impossible. By 1710 the French king had been reduced to great distress, and was compelled to make at least a show of withdrawing his support from his grandson Philip V. The allies decided to advance from Catalonia, a course which was strongly urged by General Stanhope (afterwards Earl Stanhope), who commanded the British troops. He had served in subordinate rank from the beginning of the war, and had gained some reputation by the capture of Port Mahon in 1708. Stanhope's energy overcame the reluctance of the Imperialist general Guido Starhemberg, who commanded the German troops of the archduke. The allies advanced and for a time seemed to carry all before them. The Spaniards were defeated at Alménara on the 27th of July 1710, and before Saragossa on the 20th of

August. On the 21st of September the archduke entered Madrid. But the invasion of 1710 was a repetition of the invasion of 1706. The 23,000 men of the allies, reduced by a loss of 2000 in the actions at Almenara and Saragossa, by casualties in constant skirmishes with the guerrilleros, and by disease, were absolutely incapable of occupying the two Castiles. The Portuguese gave no help. The Spaniards were reorganized by the duke of Vendôme, who was lent to King Philip V. by his grandfather, and were joined by soldiers of the Irish brigade, and by some Frenchmen who were allowed, or secretly directed, to enter the Spanish service. The position of the allies at Madrid, which was deserted by all except the poorest of its inhabitants, became untenable. On the 9th of November they evacuated the town, and began their retreat to Catalonia. The archduke left the army with 2000 cavalry, and hurried back to Barcelona. The rest of the army marched in two detachments, the division being imposed on them by difficulty of finding food. General Starhemberg with the main body of 12,000 men, was a day's march ahead of the British troops, 5000 men, under Stanhope. Such a disposition invited disaster in the presence of so capable a general as Vendôme. On the 9th of December he fell upon General Stanhope at Brihuega, and after hard fighting forced him to surrender. Starhemberg, who received tardy information of the peril of his colleague, marched back to support him, and fought a drawn battle at Villa Viciosa, on the 11th. The fruits of victory fell to Vendôme, for the Imperialist general was compelled to continue his retreat, harassed at every step by the Spanish cavalry and irregulars. His army was reduced to 7000 men when he reached Barcelona.

The disastrous result of the campaign of 1710 proved to demonstration that it was impossible to force the archduke on the Castilians by any effort the allies were prepared to make. They remained quiescent at Barcelona till they evacuated the country altogether on the Peace of Utrecht. The Catalans, though deserted by their allies, continued to fight for their local franchises which had been declared forfeited by the victorious Bourbon king. Barcelona was only subdued on the 12th of September 1714, after a siege of great length and extraordinary ferocity, by the united exertions of the French and Spanish troops under the command of the duke of Berwick.

The naval operations, apart from the transport and support of the troops in Spain, were more numerous than memorable. The overwhelming superiority of the allies alone enabled them to maintain the war in the Peninsula, but as they met no serious opposition except in 1704, there is nothing to record save their successive cruises. In 1707 a British and Dutch fleet under Sir Cloudesley Shovel aided the Imperialists in the unsuccessful siege of Toulon. The action of the allied navy was in fact as decisive as the naval strength of Great Britain was to be in the later struggle with Napoleon. But it was less brilliant. The many expeditions sent to the West Indies rarely did more than plunder coast towns or plantations in the French islands. An exception was indeed provided by the British admiral Sir Charles Wager, who in May 1708 destroyed or captured a whole squadron of Spanish treasure ships near Cartagena in South America. The loss of the treasure was a heavy blow to the government of Philip V. and had much to do with his inability to follow up the victory of Almansa. On the whole however neither the British nor the Dutch achieved any material success against the French in America. One powerful British combined force, which was sent against Quebec in 1711, was compelled to return by the shipwreck of a number of the vessels composing it at the mouth of the St Lawrence on the 21st of August. The French found some consolation for the weakness of the royal navy in the daring and the frequent success of their privateers. They were indeed the finest operations of the kind recorded in naval warfare. As the British and Dutch took measures to guard against capture of their merchant ships by sailing in well protected convoys, the French combined their privateers into squadrons and attacked the guard with great vigour. On the 20th of October 1708, a British squadron of 5 line of battleships, of which 2 were of 80 guns, conveying a number of store ships to Lisbon, was attacked near the Lizard, and was almost wholly destroyed or captured by Duguay Trouin and Forbin with 12 smaller vessels. This was but one example of a number of operations of the same character by which the trade of Great Britain and Holland was hampered. The most signal single achievement of the privateers was the capture of Rio de Janeiro from the Portuguese in September 1711 by a fleet of 6 sail-of-the-line and 6 frigates with corsairs. The royal ships were equipped as a speculation by Duguay Trouin and the shipowners of St Malo. The booty taken gave a profit of 92% on the capital invested.

Authorities.—For the war on land *The History of the War of the Succession in Spain* (London, 1832) by Lord Mahon (Stanhope) is still of value. Lord Mahon was, however, misled into placing too much confidence in Peterborough. Colonel Parnell, *The War of Succession in Spain* (London, 1888), goes perhaps into the opposite extreme, but his history is full and is supported by copious references to original authorities. The naval operations are told for Great Britain by Lediard *Naval History* (London, 1735); for Holland by De Jonghe, *Geschiedenis van het nederlansche zeewezen* (Haarlem, 1858); and for France by Tronde, *Batailles navales de la France* (Paris 1867). (D. H.)

SPARASSODONTA, a zoological name applied to a group of primitive carnivorous mammals from the Santa Cruz beds of Patagonia, represented by the genera *Borhyaena*, *Prothylacinus*, *Amphiproviverra*, &c. By their first describer, Dr F. Ameghino, they were regarded as nearly related to the marsupials. They are, however, more probably members of the creodont Carnivora (see Creodonta).

SPARKS, JARED (1789–1866), American historian and educationalist, was born in Willington, Tolland county, Connecticut, on the 10th of May 1789. He studied in the common schools, worked for a time at the carpenter's trade, and then became a school-teacher. In 1809–1811 he attended Phillips Exeter Academy, where he met John G. Palfrey and George Bancroft, two schoolmates, who became his lifelong friends. He graduated at Harvard (A.B., in 1815 and A.M., in 1818); taught in a private school at Lancaster, Massachusetts, in 1815–1817; and studied theology and was college tutor in mathematics and natural philosophy at Harvard in 1817–1819. In 1817–1818 he was acting editor of the *North American Review*. He was pastor of the First Independent Church (Unitarian) of Baltimore, Maryland, in 1819–1823, Dr William Ellery Channing delivering at his ordination his famous discourse on "Unitarian Christianity." During this period Sparks founded the *Unitarian Miscellany and Christian Monitor* (1821), a monthly, and edited its first three volumes; he was chaplain of the national House of Representatives in 1821–1823; and he contributed to the *National Intelligencer* and other periodicals. In 1823 his health failed and he withdrew from the ministry. Removing to Boston, he bought and edited in 1824–1830 the *North American Review*, contributing to it about fifty articles. He founded and edited, in 1830 the *American Almanac and Repository of Useful Knowledge*, which was continued by others and long remained a popular annual. After extensive researches at home and (1828–1829) in London and Paris, he published the *Life and Writings of George Washington* (12 vols., 1834–1837; redated 1842), his most important work; and in 1839 he published separately the *Life of George Washington* (abridged, 2 vols., 1842). The work was for the most part favourably received, but Sparks was severely criticized by Lord Mahon (in the sixth volume of his *History of England*) and others for altering the text of some of Washington's writings. Sparks defended his methods in *A Reply to the Strictures of Lord Mahon and Others* (1852). The charges were not wholly justifiable, and later Lord Mahon (Stanhope) modified them. While continuing his studies abroad, in 1840–1841, in the history of the American War of Independence, Sparks discovered in the French archives the red-line map, which, in 1842, came into international prominence in connexion with the dispute over the north-eastern boundary of the United States. In 1842 he delivered twelve lectures on American history before the Lowell Institute in Boston. In 1839–1849 he was McLean professor of ancient and modern history at Harvard. His appointment to this position, says his biographer, was "the first academic encouragement of American history, and of original historical research in the American field." In 1849 Sparks succeeded Edward Everett as president of Harvard. He retired in 1853 on account of failing health, and devoted the rest of his life to his private studies. For several years he was a member of the Massachusetts board of education. He died on the 14th of March 1866, in Cambridge, Mass. His valuable collection of manuscripts and papers went to Harvard; and his private library and his maps were bought by Cornell University. He was a pioneer in collecting, on a large scale, documentary material on American history, and in this and in other ways rendered valuable services to historical scholarship in the United States.

Among Sparks's publications not already mentioned, are *Memoirs of the Life and Travels of John Ledyard* (1828); *The Diplomatic Correspondence of the American Revolution* (12 vols., 1829–1830; redated 1854); *Life of Gouverneur Morris, with Selections from his Correspondence and Miscellaneous Papers* (3 vols., 1832); *A Collection of the Familiar Letters and Miscellaneous Papers of Benjamin Franklin* (1833); *The Works of Benjamin Franklin; with Notes and a Life of the Author* (10 vols., 1836–1840; redated 1850), a work second in scope and importance to his *Washington; Correspondence of the American Revolution; being Letters of Eminent Men to George Washington, from the Time of his taking Command of the Army to the End of his Presidency* (4 vols., 1853). He also edited the *Library of American Biography*, in two series (10 and 15 vols. respectively, 1834–1838, 1844–1847), to which he contributed the lives of Ethan Allen, Benedict Arnold, Marquette, La Salle, Count Pulaski, John Ribault, Charles Lee and John Ledyard, the last a reprint of his earlier work. In addition, he aided Henry D. Gilpin in preparing an edition of the *Papers of James Madison* (1840), and brought out an American edition of William Smyth's *Lectures on Modern History* (2 vols., 1841), which did much to stimulate historical study in the United States.

See Herbert B. Adams, *The Life and Writings of Jared Sparks* (2 vols., Boston, 1893); also Brantz Mayer, *Memoir of Jared Sparks* (1867), prepared for the Maryland Historical Society; and George E. Ellis, *Memoir of Jared Sparks* (1869), reprinted from the *Proceedings of the Massachusetts Historical Society* for May 1868.

(W. L. C.*)

SPARROW (O. Eng. *spearwa*; Icel. *spörr*; O.H.G. *Sparo*), a word perhaps (like the equivalent Latin *passer*) originally meaning almost any small bird, but gradually restricted in signification, and nowadays in common English applied to only four kinds, which are further differentiated as hedge-sparrow, house-sparrow, tree-sparrow and reed-sparrow—the last being a bunting (*q.v.*)—though when used without a prefix the second of these is usually intended.

1. The hedge-sparrow, called "dunnock" in many parts of Britain, *Accentor modularis* of the sub-family Turdinae of the thrushes (*q.v.*), is the little brown-backed bird with an iron-grey head and neck that is to be seen in nearly every garden throughout the country, unobtrusively and yet tamely seeking its food, which consists almost wholly of insects, as it progresses over the ground in short jumps, each movement being accompanied by a slight jerk or shuffle of the wings. Though on the continent of Europe it regularly migrates, it is one of the few soft-billed birds that reside throughout the year with us, and is one of the earliest breeders—its well-known greenish-blue eggs, laid in a warmly built nest, being recognized by hundreds as among the surest signs of returning spring; but a second or even a third brood is produced later. The cock has a sweet but rather feeble song; and the species has long been accounted, though not with accuracy, to be the most common dupe of the cuckoo. Several other species are assigned to the genus *Accentor*; but all, except the Japanese *A. rubidus*, which is the counterpart of the British hedge-sparrow, inhabit more or less rocky situations, and one, *A. collaris*, or *alpinus*, is a denizen of the higher mountain-ranges of Europe, though it has several times strayed to England.

2. The house-sparrow, the *Fringilla domestica* of Linnaeus and *Passer domesticus* of modern authors, is far too well known to need any description of its appearance or habits, being found, whether in country or town, more attached to human dwellings than any other wild bird; nay, more than that, one may safely assert that it is not known to thrive anywhere far away from the habitations or works of men, extending its range in such countries as northern Scandinavia and many parts of the Russian Empire as new settlements are formed and land brought under cultivation. Thus questions arise as to whether it should not be considered a parasite throughout the greater portion of the area it now occupies, and as to what may have been its native country. Moreover, it has been introduced to several of the large towns of North America and to many of the British colonies, in nearly all of which, as had been foreseen by ornithologists, it has multiplied to excess and has become an intolerable nuisance, being unrestrained by the natural checks which partly restrict its increase in Europe and Asia. Whether indeed in the older seats of civilization the house-sparrow is not decidedly injurious to the agriculturist and horticulturist has long been a matter of discussion, and no definite result that a fair judge can accept has yet been reached. It is freely admitted that the damage done to growing crops is often enormous, but as yet the service frequently rendered by the destruction of insect-pests cannot be calculated. In the south of Europe the house-sparrow is in some measure replaced by two allied species, *P. hispaniolensis* and *P. italiae*, whose habits are essentially identical with its own; and it is doubtful whether the sparrow of India, *P. indicus*, is specifically distinct; but Africa has several members of the genus which are decidedly so.

3. The tree-sparrow, the *Fringilla montana* of Linnaeus and *Passer montanus* of modern writers—both sexes of which much resemble the male house-sparrow, but are easily distinguishable by the reddish-brown crown, the black patch on the sides of the neck, and doubly-barred wings—is a much more local species, in England generally frequenting the rows of pollard-willows that line so many rivers and canals, in the holes of which it breeds; but in some Eastern countries, and especially in China, it frequents houses, even in towns, and so fills the place of the house-sparrow. Its geographical distribution is extensive and marked by some curious characters, among which may be mentioned that, being a great wanderer, it has effected settlements even in such remote islands as the Faeroes and some of the Outer Hebrides.

The genus *Passer* belongs to the Passerine family Fringillidae. The American birds called "sparrows" have little in common with the members of the genus *Passer*, and belong to the family Emberizidae, which is closely allied to the Fringillidae. (A. N.)

SPARTA (Gr. Σπάρτη or Λακεδαίμων), an ancient city in Greece, the capital of Laconia and the most powerful state of the Peloponnese. The city lay at the northern end of the central Laconian plain, on the right bank of the river Eurotas, a little south of the point where it is joined by its largest tributary, the Oenus (mod. Kelefína). The site is admirably fitted by nature to guard the only routes by which an army can penetrate Laconia from the land side, the Oenus and Eurotas valleys leading from Arcadia, its northern neighbour, and the Langáda Pass over Mt Taygetus connecting Laconia and Messenia. At the same time its distance from the sea—Sparta is 27 m. from its seaport, Gythium—made it invulnerable to a maritime attack.

I.—History

Prehistoric Period.—Tradition relates that Sparta was founded by Lacedaemon, son of Zeus and Taygete, who called the city after the name of his wife, the daughter of Eurotas. But Amyclae and Therapne (Therapnae) seem to have been in early times of greater importance than Sparta, the former a Minyan foundation a few miles to the south of Sparta, the latter probably the Achaean capital of Laconia and the seat of Menelaus, Agamemnon's younger brother. Eighty years after the Trojan War, according to the traditional chronology, the Dorian migration took place. A band of Dorians (*q.v.*) united with a body of Aetolians to cross the Corinthian Gulf and invade the Peloponnese from the north-west. The Aetolians settled in Elis, the Dorians pushed up to the headwaters of the Alpheus, where they divided into two forces, one of which under Cresphontes invaded and later subdued Messenia, while the other, led by Aristodemus or, according to another version, by his twin sons Eurysthenes and Procles, made its way down the Eurotas valley and gained Sparta, which became the Dorian capital

Dorian Invasion.

of Laconia. In reality this Dorian immigration probably consisted of a series of inroads and settlements rather than a single great expedition, as depicted by legend, and was aided by the Minyan elements in the population, owing to their dislike of the Achaean yoke. The newly founded state did not at once become powerful: it was weakened by internal dissension and lacked the stability of a united and well-organized community. The turning-point is marked by the legislation of Lycurgus (*q.v.*), who effected the unification of the state and instituted that training which was its distinguishing feature and the source of its greatness. Nowhere else in the Greek world was the pleasure of the individual so thoroughly subordinated to the interest of the state. The whole education of the Spartan was designed to make him an efficient soldier. Obedience, endurance, military success—these were the aims constantly kept in view, and beside these all other ends took a secondary place. Never, perhaps, in the world's history has a state so clearly set a definite ideal before itself or striven so consistently to reach it. But it was solely in this consistency and steadfastness that the greatness of Sparta lay. Her ideal was a narrow and unworthy one, and was pursued with a calculating selfishness and a total disregard for the rights of others, which robbed it of the moral worth it might otherwise have possessed. Nevertheless, it is not probable that without the training introduced by Lycurgus the Spartans would have been successful in securing their supremacy in Laconia, much less in the Peloponnese, for they formed a small immigrant band face to face with a large and powerful Achaean and autochthonous population.

The Expansion of Sparta.—We cannot trace in detail the process by which Sparta subjugated the whole of Laconia, but apparently the first step, taken in the reign of Archelaus and Charillus, was to secure the upper Eurotas valley, conquering the border territory of Aegys. Archelaus' son Teleclus is said to have taken Amyclae, Pharis and Geronthrae, thus mastering the central Laconian plain and the eastern plateau which lies between the Eurotas and Mt Parnon: his son, Alcamenes, by the subjugation of Helos brought the lower Eurotas plain under Spartan rule. About this time, probably, the Argives, whose territory included the whole east coast of the Peloponnese and the island of Cythera (Herod. i. 82), were driven back, and the whole of Laconia was thus incorporated in the Spartan state. It was not long before a further extension took place. Under Alcamenes and Theopompus a war broke out between the Spartans and the Messenians, their neighbours on the west, which, after a struggle lasting for twenty years, ended in the capture of the stronghold of Ithome and the subjection of the Messenians, who were forced to pay half the produce of the soil as tribute to their Spartan overlords. An attempt to throw off the yoke resulted in a second war, conducted by the Messenian hero Aristomenes (*q.v.*); but Spartan tenacity broke down the resistance of the insurgents, and Messenia was made Spartan territory, just as Laconia had been, its inhabitants being reduced to the status of helots, save those who, as perioeci, inhabited the towns on the sea-coast and a few settlements inland.

Messenian Wars.

This extension of Sparta's territory was viewed with apprehension by her neighbours in the Peloponnese. Arcadia and Argos had vigorously aided the Messenians in their two struggles, and help was also sent by the Sicyonians, Pisatans and Triphylians: only the Corinthians appear to have supported the Spartans, doubtless on account of their jealousy of their powerful neighbours, the Argives. At the close of the second Messenian War, *i.e.* by the war 631 at latest, no power could hope to cope with that of Sparta save Arcadia and Argos. Early in the 6th century the Spartan kings Leon and Agasicles made a vigorous attack on Tegea, the most powerful of the Arcadian cities, but it was not until the reign of Anaxandridas and Ariston, about the middle of the century, that the attack was successful and Tegea was forced to acknowledge Spartan overlordship, though retaining its independence. The final struggle for Peloponnesian supremacy was with Argos, which had at an early period been the most powerful state of the peninsula, and even now, though its territory had been curtailed, was a serious rival of Sparta. But Argos was now no longer at the height of its power: its league had begun to break up early in the century, and it could not in the impending struggle count on the assistance of its old allies, Arcadia and Messenia, since the latter had been crushed and robbed of its independence and the former had acknowledged Spartan supremacy. A victory won about 546 B.C., when the Lydian Empire fell before Cyrus of Persia, made the Spartans masters of the Cynuria, the borderland between Laconia and Argolis, for which there had been an age-long struggle. The final blow was struck by King Cleomenes I. (*q.v.*), who maimed for many years to come the Argive power and left Sparta without a rival in the Peloponnese. In fact, by the middle of the 6th century, and increasingly down to the period of the Persian Wars, Sparta had come to be acknowledged as the leading state of Hellas and the champion of Hellenism. Croesus of Lydia had formed an alliance with her. Scythian envoys sought her aid to stem the invasion of Darius; to her the Greeks of Asia Minor appealed to withstand the Persian advance and to aid the Ionian revolt; Plataea asked for her protection; Megara acknowledged her supremacy; and at the time of the Persian invasion under Xerxes no state questioned her right to lead the Greek forces on land and sea. Of such a position Sparta proved herself wholly unworthy. As an ally she was ineffective, nor could she ever rid herself of her narrowly Peloponnesian outlook sufficiently to throw herself heartily into the affairs of the greater Hellas that lay beyond the isthmus and across the sea. She was not a colonizing state, though the inhabitants of Tarentum, in southern Italy, and of Lyttus, in Crete, claimed her as their mother-city. Moreover, she had no share in the expansion of Greek commerce and Greek culture; and, though she bore the reputation of hating tyrants and putting them down where possible, there can be little doubt that this was done in the interests of oligarchy rather than of liberty. Her military greatness and that of the states under her hegemony formed her sole claim to lead the Greek race: that she should truly represent it was impossible.

Argive Wars.

Constitution.—Of the internal development of Sparta down to this time but little is recorded. This want of information was attributed by most of the Greeks to the stability of the Spartan constitution, which had lasted unchanged from the days of Lycurgus. But it is, in fact, due also to the absence of an historical literature at Sparta, to the small part played by written laws, which were, according to tradition, expressly prohibited by an ordinance of Lycurgus, and to the secrecy which always characterizes an oligarchical rule. At the head of the state stood two hereditary kings, of the Agiad and Eurypontid families, equal in authority, so that one could not act against the veto of his colleague, though the Agiad king received greater honour in virtue of the seniority of his family (Herod. vi. 51). This dual kingship, a phenomenon unique in Greek history, was explained in Sparta by the tradition that on Aristodemus's death he had been succeeded by his twin sons, and that this joint rule had been perpetuated. Modern scholars have advanced various theories to account for the anomaly. Some suppose that it must be explained as an attempt to avoid absolutism, and is paralleled by the analogous instance of the consuls at Rome. Others think that it points to a compromise arrived at to end the struggle between two families or communities, or that the two royal houses represent respectively the Spartan conquerors and their Achaean predecessors: those who hold this last view appeal to the words attributed by Herodotus (v. 72) to Cleomenes I.: "I am no Dorian, but an Achaean." The duties of the kings were mainly religious, judicial and military. They were the chief priests of the state, and had to perform certain sacrifices and to maintain communication with the Delphian sanctuary, which always exercised great authority in Spartan politics. Their judicial functions had at the time when Herodotus wrote (about 430 B.C.) been restricted to cases dealing with heiresses, adoptions and the public roads: civil cases were decided by the ephors,

Kingship.

criminal jurisdiction had passed to the council of elders and the ephors. It was in the military sphere that the powers of the kings were most unrestricted. Aristotle describes the kingship at Sparta as "a kind of unlimited and perpetual generalship" (*Pol.* iii. 1285*a*), while Isocrates refers to the Spartans as "subject to an oligarchy at home, to a kingship on campaign" (iii. 24). Here also, however, the royal prerogatives were curtailed in course of time: from the period of the Persian wars the king lost the right of declaring war on whom he pleased, he was accompanied to the field by two ephors, and he was supplanted also by the ephors in the control of foreign policy. More and more, as time went on, the kings became mere figure-heads, except in their capacity as generals, and the real power was transferred to the ephors and to the gerousia (*q.v.*). The reason for this change lay partly in the fact that the ephors, chosen by popular election from the whole body of citizens, represented a democratic element in the constitution without violating those oligarchical methods which seemed necessary for its satisfactory administration; partly in the weakness of the kingship, the dual character of which inevitably gave rise to jealousy and discord between the two holders of the office, often resulting in a practical deadlock; partly in the loss of prestige suffered by the kingship, especially during the 5th century, owing to these quarrels, to the frequency with which kings ascended the throne as minors and a regency was necessary, and to the many cases in which a king was, rightly or wrongly, suspected of having accepted bribes from the enemies of the state and was condemned and banished. In the powers exercised by the assembly of the citizens or apella (*q.v.*) we cannot trace any development, owing to the scantiness of our sources. The Spartan was essentially a soldier, trained to obedience and endurance: he became a politician only if chosen as ephor for a single year or elected a life member of the council after his sixtieth year had brought freedom from military service.

Training of Citizens.

Shortly after birth the child was brought before the elders of the tribe, who decided whether it was to be reared: if defective or weakly, it was exposed in the so-called *Apothetae* (αἱ 'Αποθέται, from ἀπόθετος, hidden). Thus was secured, as far as could be, the maintenance of a high standard of physical efficiency, and thus from the earliest days of the Spartan the absolute claim of the state to his life and service was indicated and enforced. Till their seventh year boys were educated at home: from that time their training was undertaken by the state and supervised by the παιδονόμος, an official appointed for that purpose. This training consisted for the most part in physical exercises, such as dancing, gymnastics, ball-games, &c., with music and literature occupying a subordinate position. From the twentieth year began the Spartan's liability to military service and his membership of one of the ἀνδρεῖα or φιδίτια (dining messes or clubs), composed of about fifteen members each, to one of which every citizen must belong. At thirty began the full citizen rights and duties. For the exercise of these three conditions were requisite: Spartiate birth, the training prescribed by law, and participation in and contribution to one of the dining-clubs. Those who fulfilled these conditions were the ὅμοιοι (peers), citizens in the fullest sense of the word, while those who failed were called ὑπομείονες (lesser men), and retained only the civil rights of citizenship.

Social System.

Spartiates were absolutely debarred by law from trade or manufacture, which consequently rested in the hands of the perioeci (*q.v.*), and were forbidden to possess either gold or silver, the currency consisting of bars of iron: but there can be no doubt that this prohibition was evaded in various ways. Wealth was, in theory at least, derived entirely from landed property, and consisted in the annual return made by the helots (*q.v.*) who cultivated the plots of ground allotted to the Spartiates. But this attempt to equalize property proved a failure: from early times there were marked differences of wealth within the state, and these became even more serious after the law of Epitadeus, passed at some time after the Peloponnesian War, removed the legal prohibition of the gift or bequest of land. Later we find the soil coming more and more into the possession of large landholders, and by the middle of the 3rd century B.C. nearly two-fifths of Laconia belonged to women. Hand in hand with this process went a serious diminution in the number of full citizens, who had numbered 8000 at the beginning of the 5th century, but had sunk by Aristotle's day to less than 1000, and had further decreased to 700 at the accession of Agis IV. in 244 B.C. The Spartans did what they could to remedy this by law: certain penalties were imposed upon those who remained unmarried or who married too late in life. But the decay was too deep-rooted to be eradicated by such means, and we shall see that at a late period in Sparta's history an attempt was made without success to deal with the evil by much more drastic measures.

The 5th Century B.C.—The beginning of the 5th century saw Sparta at the height of her power, though her prestige must have suffered in the fruitless attempts made to impose upon Athens an oligarchical régime after the fall of the Peisistratid tyranny in 510. But after the Persian Wars the Spartan supremacy could no longer remain unchallenged. Sparta had despatched an army in 490 to aid Athens in repelling the armament sent against it by Darius under the command of Datis and Artaphernes: but it arrived after the battle of Marathon had been fought and the issue of the conflict decided. In the second campaign, conducted ten years later by Xerxes in person, Sparta took a more active share and assumed the command of the combined Greek forces by sea and land. Yet, in spite of the heroic defence of Thermopylae by the Spartan king Leonidas (*q.v.*), the glory of the decisive victory at Salamis fell in great measure to the Athenians, and their patriotism, self-sacrifice and energy contrasted strongly with the hesitation of the Spartans and the selfish policy which they advocated of defending the Peloponnese only. By the battle of Plataea (479 B.C.), won by a Spartan general, and decided chiefly by the steadfastness of Spartan troops, the state partially recovered its prestige, but only so far as land operations were concerned: the victory of Mycale, won in the same year, was achieved by the united Greek fleet, and the capture of Sestos, which followed, was due to the Athenians, the Peloponnesians having returned home before the siege was begun. Sparta felt that an effort was necessary to recover her position, and Pausanias, the victor of Plataea, was sent out as admiral of the Greek fleet. But though he won considerable successes, his overbearing and despotic behaviour and the suspicion that he was intriguing with the Persian king alienated the sympathies of those under his command: he was recalled by the ephors, and his successor, Dorcis, was a weak man who allowed the transference of the hegemony from Sparta to Athens to take place without striking a blow (see DELIAN LEAGUE). By the withdrawal of Sparta and her Peloponnesian allies from the fleet the perils and the glories of the Persian War were left to Athens, who, though at the outset merely the leading state in a confederacy of free allies, soon began to make herself the mistress of an empire. Sparta took no steps at first to prevent this. Her interests and those of Athens did not directly clash, for Athens included in her empire only the islands of the Aegean and the towns on its north and east coasts, which lay outside the Spartan political horizon: with the Peloponnese Athens did not meddle. Moreover, Sparta's attention was at this time fully occupied by troubles nearer home—the plots of Pausanias not only with the Persian king but with the Laconian helots; the revolt of Tegea (*c.* 473–71), rendered all the more formidable by the participation of Argos; the earthquake which in 464 devastated Sparta; and the rising of the Messenian helots, which immediately followed. But there was a growing estrangement from Athens, which ended at length in an open breach. The insulting dismissal of a large body of Athenian troops which had come, under Cimon, to aid the Spartans in the siege of the Messenian stronghold of Ithome, the consummation of the Attic democracy under Ephialtes and Pericles, the conclusion of an alliance between Athens

Persian Wars.

War with Athens.

and Argos, which also about this time became democratic, united with other causes to bring about a rupture between the Athenians and the Peloponnesian League. In this so-called first Peloponnesian War Sparta herself took but a small share beyond helping to inflict a defeat on the Athenians at Tanagra in 457 B.C. After this battle they concluded a truce, which gave the Athenians an opportunity of taking their revenge on the Boeotians at the battle of Oenophyta, of annexing to their empire Boeotia, Phocis and Locris, and of subjugating Aegina. In 449 the war was ended by a five years' truce, but after Athens had lost her mainland empire by the battle of Coronea and the revolt of Megara a thirty years' peace was concluded, probably in the winter 446–445 B.C. By this Athens was obliged to surrender Troezen, Achaea and the two Megarian ports, Nisaea and Pegae, but otherwise the *status quo* was maintained. A fresh struggle, the great Peloponnesian War (*q.v.*), broke out in 431 B.C. This may be to a certain extent regarded as a contest between Ionian and Dorian; it may with greater truth be called a struggle between the democratic and oligarchic principles of government; but at bottom its cause was neither racial nor constitutional, but economic. The maritime supremacy of Athens was used for commercial purposes, and important members of the Peloponnesian confederacy, whose wealth depended largely on their commerce, notably Corinth, Megara, Sicyon and Epidaurus, were being slowly but relentlessly crushed. Materially Sparta must have remained almost unaffected, but she was forced to take action by the pressure of her allies and by the necessities imposed by her position as head of the league. She did not, however, prosecute the war with any marked vigour: her operations were almost confined to an annual inroad into Attica, and when in 425 a body of Spartiates was captured by the Athenians at Pylos she was ready, and even anxious, to terminate the war on any reasonable conditions. That the terms of the Peace of Nicias, which in 421 concluded the first phase of the war, were rather in favour of Sparta than of Athens was due almost entirely to the energy and insight of an individual Spartan, Brasidas (*q.v.*), and the disastrous attempt of Athens to regain its lost land-empire. The final success of Sparta and the capture of Athens in 405 were brought about partly by the treachery of Alcibiades, who induced the state to send Gylippus to conduct the defence of Syracuse, to fortify Decelea in northern Attica, and to adopt a vigorous policy of aiding Athenian allies to revolt. The lack of funds which would have proved fatal to Spartan naval warfare was remedied by the intervention of Persia, which supplied large subsidies, and Spartan good fortune culminated in the possession at this time of an admiral of boundless vigour and considerable military ability, Lysander, to whom much of Sparta's success is attributable.

Peloponnesian War.

The 4th Century.—The fall of Athens left Sparta once again supreme in the Greek world and demonstrated clearly her total unfitness for rule. Everywhere democracy was replaced by a philo-Laconian oligarchy, usually consisting of ten men under a harmost or governor pledged to Spartan interests, and even in Laconia itself the narrow and selfish character of the Spartan rule led to a serious conspiracy. For a short time, indeed, under the energetic rule of Agesilaus, it seemed as if Sparta would pursue a Hellenic policy and carry on the war against Persia. But troubles soon broke out in Greece, Agesilaus was recalled from Asia Minor, and his schemes and successes were rendered fruitless. Further, the naval activity displayed by Sparta during the closing years of the Peloponnesian War abated when Persian subsidies were withdrawn, and the ambitious projects of Lysander led to his disgrace, which was followed by his death at Haliartus in 395. In the following year the Spartan navy under Peisander, Agesilaus' brother-in-law, was defeated off Cnidus by the Persian fleet under Conon and Pharnabazus, and for the future Sparta ceased to be a maritime power. In Greece itself meanwhile the opposition to Sparta was growing increasingly powerful, and, though at Coronea Agesilaus had slightly the better of the Boeotians and at Corinth the Spartans maintained their position, yet they felt it necessary to rid themselves of Persian hostility and if possible use the Persian power to strengthen their own position at home: they therefore concluded with Artaxerxes II. the humiliating Peace of Antalcidas (387 B.C.), by which they surrendered to the Great King the Greek cities of the Asia Minor coast and of Cyprus, and stipulated for the independence of all other Greek cities. This last clause led to a long and desultory war with Thebes, which refused to acknowledge the independence of the Boeotian towns under its hegemony: the Cadmeia, the citadel of Thebes, was treacherously seized by Phoebidas in 382 and held by the Spartans until 379. Still more momentous was the Spartan action in crushing the Olynthiac Confederation (see OLYNTHUS), which might have been able to stay the growth of Macedonian power. In 371 a fresh peace congress was summoned at Sparta to ratify the Peace of Callias. Again the Thebans refused to renounce their Boeotian hegemony, and the Spartan attempt at coercion ended in the defeat of the Spartan army at the battle of Leuctra and the death of its leader, King Cleombrotus. The result of the battle was to transfer the Greek supremacy from Sparta to Thebes.

Spartan Empire.

In the course of three expeditions to the Peloponnese conducted by Epaminondas, the greatest soldier and statesman Thebes ever produced, Sparta was weakened by the loss of Messenia, which was restored to an independent position with the newly built Messene as its capital, and by the foundation of Megalopolis as the capital of Arcadia. The invading army even made its way into Laconia and devastated the whole of its southern portion; but the courage and coolness of Agesilaus saved Sparta itself from attack. On Epaminondas' fourth expedition Sparta was again within an ace of capture, but once more the danger was averted just in time; and though at Mantinea (362 B.C.) the Thebans, together with the Arcadians, Messenians and Argives, gained a victory over the combined Mantinean, Athenian and Spartan forces, yet the death of Epaminondas in the battle more than counterbalanced the Theban victory and led to the speedy break-up of their supremacy. But Sparta had neither the men nor the money to recover her lost position, and the continued existence on her borders of an independent Messenia and Arcadia kept her in constant fear for her own safety. She did, indeed, join with Athens and Achaea in 353 to prevent Philip of Macedon passing Thermopylae and entering Phocis, but beyond this she took no part in the struggle of Greece with the new power which had sprung up on her northern borders. No Spartiate fought on the field of Chaeronea. After the battle, however, she refused to submit voluntarily to Philip, and was forced to do so by the devastation of Laconia and the transference of certain border districts to the neighbouring states of Argos, Arcadia and Messenia. During the absence of Alexander the Great in the East Agis III. revolted, but the rising was crushed by Antipater, and a similar attempt to throw off the Macedonian yoke made by Archidamus IV. in the troublous period which succeeded Alexander's death was frustrated by Demetrius Poliorcetes in 294 B.C. Twenty-two years later the city was attacked by an immense force under Pyrrhus, but Spartan bravery had not died out and the formidable enemy was repulsed, even the women taking part in the defence of the city. About 244 an Aetolian army overran Laconia, working irreparable harm and carrying off, it is said, 50,000 captives.

Decline of Sparta.

Rise of Macedon.

But the social evils within the state were even harder to combat than foes without. Avarice, luxury and the glaring inequality in the distribution of wealth, threatened to bring about the speedy fall of the state if no cure could be found. Agis IV. and Cleomenes III. (*qq.v.*) made an heroic and entirely disinterested attempt in the latter part of the 3rd century to improve the conditions by a redistribution of land, a widening of the citizen body, and a restoration of the old severe training and simple life. But the evil was too deep-seated to be remedied by these artificial means; Agis was assassinated, and the reforms of Cleomenes seem to have had no permanent effect. The reign of Cleomenes is marked also by a determined effort to cope with the rising power of the Achaean League (*q.v.*) and to recover for Sparta her long-lost supremacy in the Peloponnese, and even throughout Greece. The battle of Sellasia (222 B.C.), in which Cleomenes was defeated by the Achaeans and Antigonus Doson of Macedonia, and the death of the king, which occurred shortly afterwards in Egypt, put an end to these hopes. The same reign saw also an important constitutional change, the substitution of a board of patronomi for the ephors, whose power had become almost despotic, and the curtailment of the functions exercised by the gerousia; these measures were, however, cancelled by Antigonus. It was not long afterwards that the dual kingship ceased and Sparta fell under the sway of a series of cruel and rapacious tyrants—Lycurgus, Machanidas, who was killed by Philopoemen, and Nabis, who, if we may trust the accounts given by Polybius and Livy, was little better than a bandit chieftain, holding Sparta by means of extreme cruelty and oppression, and using mercenary troops to a large extent in his wars.

The Intervention of Rome.—We must admit, however, that a vigorous struggle was maintained with the Achaean League and with Macedon until the Romans, after the conclusion of their war with Philip V., sent an army into Laconia under T. Quinctius Flamininus. Nabis was forced to capitulate, evacuating all his possessions outside Laconia, surrendering the Laconian seaports and his navy, and paying an indemnity of 500 talents (Livy xxxiv. 33-43). On the departure of the Romans he succeeded in recovering Gythium, in spite of an attempt to relieve it made by the Achaeans under Philopoemen, but in an encounter he suffered a crushing defeat at the hands of that general, who for thirty days ravaged Laconia unopposed. Nabis was assassinated in 192, and Sparta was forced by Philopoemen to enrol itself as a member of the Achaean League (*q.v.*) under a phil-Achaean aristocracy. But this

Achaean League.

gave rise to chronic disorders and disputes, which led to armed intervention on the part of the Achaeans, who compelled the Spartans to submit to the overthrow of their city walls, the dismissal of their mercenary troops, the recall of all exiles, the abandonment of the old Lycurgan constitution and the adoption of the Achaean laws and institutions (188 B.C.). Again and again the relations between the Spartans and the Achaean League formed the occasion of discussions in the Roman senate or of the despatch of Roman embassies to Greece, but no decisive intervention took place until a fresh dispute about the position of Sparta in the league led to a decision of the Romans that Sparta, Corinth, Argos, Arcadian Orchomenus and Heraclea on Oeta should be severed from it. This resulted in an open breach between the league and Rome, and eventually, in 146 B.C., after the sack of Corinth, in the dissolution of the league and the annexation of Greece to the Roman province of Macedonia. For Sparta the long era of war and intestine struggle had ceased and one of peace and a revived prosperity took its place, as is witnessed by the numerous extant inscriptions belonging to this period As an allied city it was exempt from direct taxation, though compelled on occasions to make "voluntary" presents to Roman generals. Political ambition was restricted to the tenure of the municipal magistracies, culminating in the offices of nomophylax, ephor and patronomus. Augustus showed marked favour to the city, Hadrian twice visited it during his journeys in the East and accepted the title of eponymous patronomus. The old warlike spirit found an outlet chiefly in the vigorous but peaceful contests held in the gymnasium, the ball-place, and the arena before the temple of Artemis Orthia: sometimes too it found a vent in actual campaigning, as when Spartans were enrolled for service against the Parthians by the emperors Lucius Verus, Septimius Severus and Caracalla. Laconia was subsequently overrun, like so much of the Roman Empire, by barbarian hordes.

Medieval Sparta.—In A.D. 396 Alaric destroyed the city and at a later period Laconia was invaded and settled by Slavonic tribes, especially the Melings and Ezerits, who in turn had to give way before the advance of the Byzantine power, though preserving a partial independence in the mountainous regions. The Franks on their arrival in the Morea found a fortified city named Lacedaemonia occupying part of the site of ancient Sparta, and this continued to exist, though greatly depopulated, even after Guillaume de Villehardouin had in 1248-1249 founded the fortress and city of Misithra, or Mistra, on a spur of Taygetus some 3 m. north-west of Sparta. This passed shortly afterwards into the hands of the Byzantines, who retained it until the Turks under Mahommed II. captured it in 1460. In 1687 it came into the possession of the Venetians, from whom it was wrested in 1715 by the Turks. Thus for nearly six centuries it was Mistra and not Sparta which formed the centre and focus of Laconian history.

The Modern City.—In 1834, after the War of Independence had resulted in the liberation of Greece, the modern town of Sparta was built on part of the ancient site from the designs of Baron Jochmus, and Mistra decayed until now it is in ruins and almost deserted. Sparta is the capital of the prefecture (*νομός*) of Lacedaemon and has a population, according to the census taken in 1907, of 4456: but with the exception of several silk factories there is but little industry, and the development of the city is hampered by the unhealthiness of its situation, its distance from the sea and the absence of railway communication with the rest of Greece. As a result of popular clamour, however, a survey for a railway was begun in 1907, an event of great importance for the prosperity of Sparta and of the whole Eurotas Plain.

II.—Archaeology

There is a well-known passage in Thucydides which runs thus: "Suppose the city of Sparta to be deserted, and nothing left but the temples and the ground-plan, distant ages would be very unwilling to believe that the power of the Lacedaemonians was at all equal to their fame. . . . Their city is not built continuously, and has no splendid temples or other edifices; it rather resembles a group of villages, like the ancient towns of Hellas, and would therefore make a poor show" (i. 10, trans. Jowett). And the first feeling of most travellers who visit modern Sparta is one of disappointment with the ancient remains: it is rather the loveliness and grandeur of the situation and the fascination of Mistra, with its grass-grown streets, its decaying houses, its ruined fortress and its beautiful Byzantine churches, that remain as a lasting and cherished memory. Until 1905 the chief ancient buildings at Sparta were the theatre, of which, however, little shows above ground except portions of the retaining walls; the so-called Tomb of Leonidas, a quadrangular building, perhaps a temple, constructed of immense blocks of stone and containing two chambers; the foundation of an ancient bridge over the Eurotas; the ruins of a circular structure; some remains of late Roman fortifications; several brick buildings and mosaic pavements. To these must be added the inscriptions, sculptures and other objects collected in the local museum, founded by Stamatakis in 1872 and enlarged in 1907, or built into the walls of houses or churches. Though excavations were carried on near Sparta, on the site of the Amyclaeum in 1890 by Tsountas, and in 1904 by Furtwängler, and at the shrine of Menelaus in Therapne by Ross in 1833 and 1841, and by Kastriotis in 1889 and 1900, yet no organized work was tried in Sparta itself save the partial excavation of the "round building" undertaken in 1892 and 1893 by the American School at Athens; the structure has been since found to be a semicircular retaining-wall of good Hellenic work, though partly restored in Roman times.

In 1904 the British School at Athens began a thorough exploration of Laconia, and in the following year excavations were made at Thalamae, Geronthrae, and Angelona near Monemvasia, while several medieval fortresses were surveyed. In 1906 excavations began in Sparta itself with results of great value, which have been published in the *British School Annual*, vol. xii. sqq.

A "small circus" described by Leake, but subsequently almost lost to view, proved to be a theatre-like building constructed soon after A.D. 200 round the altar and in front of the temple of Artemis Orthia. Here musical and gymnastic contests took place as well as the famous flogging-ordeal (*diamastigosis*). The temple, which can be dated to the 2nd century B.C. rests on the foundation of an older temple of the 6th century, and close beside it were found the scanty remains of a yet earlier temple, dating from the 9th or even the 10th century. The votive offerings in clay, amber, bronze, ivory and lead found in great profusion within the precinct range from the 9th to the 4th century B.C. and supply invaluable evidence for early Spartan art; they prove that Sparta reached her artistic zenith in the 7th century and that her decline had already begun in the 6th. In 1907 the sanctuary of Athena "of the Brazen House" (Χαλκίοικος) was located on the Acropolis immediately above the theatre, and though the actual temple is almost completely destroyed, fragments of the capitals show that it was Doric in style, and the site has produced the longest extant archaic inscription of Laconia, numerous bronze nails and plates and a considerable number of votive offerings, some of them of great interest. The Greek city-wall, built in successive stages from the 4th to the 2nd century, was traced for a great part of its circuit, which measured 48 stades or nearly 6 m. (Polyb. ix. 21). The late Roman wall enclosing the Acropolis, part of which probably dates from the years following the Gothic raid of A.D. 262, was also investigated. Besides the actual buildings discovered, a number of points were fixed which greatly facilitate the study of Spartan topography, based upon the description left us by Pausanias. Excavations carried on in 1910 showed that the town of the "Mycenean" period which lay on the left bank of the Eurotas a little to the south-east of Sparta was roughly triangular in shape, with its apex towards the north: its area is approximately equal to that of Sparta, but denudation and destruction have wrought havoc with its buildings and nothing is left save ruined foundations and broken potsherds.

SPARTACUS, leader in the Slave or Gladiatorial War against Rome (73–71 B.C.), a Thracian by birth. He served in the Roman army, but seems to have deserted, for we are told that he was taken prisoner and sold as a slave. Destined for the arena, he, with a band of his fellow-gladiators, broke out of a training school at Capua and took refuge on Mt Vesuvius (73). Here he maintained himself as a captain of brigands, his lieutenants being two Celts named Crixus and Oenomaus, who like himself had been gladiators. A hastily collected force of 3000 men under C. Claudius Pulcher endeavoured to starve out the rebels, but the latter clambered down the precipices and put the Romans to flight. Swarms of hardy and desperate men now joined the rebels, and when the praetor Publius Varinius took the field against them he found them entrenched like a regular army on the plain. But they gave him the slip, and when he advanced to storm their lines he found them deserted. From Campania the rebels marched into Lucania, a country better suited for guerrilla warfare. Varinius followed, but was defeated in several engagements and narrowly escaped being taken prisoner. The insurgents reoccupied Campania, and by the defeat of C. Thoranius, the quaestor of Varinius, obtained possession of nearly the whole of southern Italy. Nola and Nuceria in Campania, Thurii and Metapontum in Lucania were sacked. The senate at last despatched both consuls against the rebels (72). The German slaves under Crixus were defeated at Mt Garganus in Apulia by the praetor Q. Arrius. But Spartacus overthrew both consuls, one after the other, and then pressed towards the Alps. Gaius Cassius, governor of Cisalpine Gaul, and the praetor Gnaeus Manlius, who attempted to stop him, were defeated at Mutina. Freedom was within sight, but with fatal infatuation the slaves refused to abandon Italy. Spartacus led them against Rome, but their hearts seem to have failed them; and instead of attacking the capital, he passed on again to Lucania. The conduct of the war was now entrusted to the praetor Marcus Licinius Crassus. In the next battle Spartacus was worsted and retreated towards the straits of Messina, intending to cross into Sicily, where he would have been welcomed by fresh hordes of slaves; but the pirates who had agreed to transport his army proved faithless. Crassus endeavoured to shut in the rebels by carrying a ditch and rampart right across the peninsula, but Spartacus forced the lines, and once more Italy lay at his feet. Disunion, however, was at work in the rebel camp. The Gauls and Germans, who had withdrawn from the main body, were attacked and destroyed. Spartacus now took up a strong position in the mountainous country of Petelia (near Strongoli in Calabria) and inflicted a severe defeat on the vanguard of the pursuing army. But his men refused to retreat farther, and in a pitched battle which followed soon afterwards the rebel army was annihilated. Spartacus, who had stabbed his horse before the battle, fell sword in hand. A body of the rebels which had escaped from the field was met and cut to pieces at the foot of the Alps by Pompey (the Great), who was returning from Spain. Pompey claimed the credit of finishing the war, and received the honour of a triumph, while only a simple ovation was decreed to Crassus. Spartacus was a capable and energetic leader; he did his best to check the excesses of the lawless bands which he commanded, and treated his prisoners with humanity. His character has been misrepresented by Roman writers, whom his name inspired with terror down to the times of the empire.

The story has to be pieced together from the vague and somewhat discrepant accounts of Plutarch (*Crassus*, 8–11; *Pompey*, 21), Appian (*Bell. civ.* i. 116–120), Florus, (ii. 8), Livy (*Epit.* 95–97), and the fragments of the *Histories* of Sallust, whose account seems to have been full and graphic.

SPARTANBURG, a city and the county-seat of Spartanburg county South Carolina, U.S.A., about 94 m. N.W. of Columbia. Pop. (1890), 5544; (1900), 11,395, of whom 4269 were negroes; **(1910 census), 17,517.** Spartanburg is served by the Southern, the Charleston & Western Carolina (controlled by the Atlantic Coast line), the Glenn Springs, the Carolina, Clinchfield & Ohio, and inter-urban (electric) railways. It is a thriving city in a cotton-growing and cotton-manufacturing region, about 800 ft. above the sea and 25 m. S.E. of the Blue Ridge. Spartanburg is the seat of Wofford College (Methodist Episcopal, South; founded in 1850 with a bequest of Benjamin Wofford, a local Methodist minister, and opened in 1854), which had, in 1908, 12 instructors and 286 students; also of Converse College (nonsectarian; for women), which was founded by D. E. Converse in 1889, opened in 1890, and in 1908 had 22 instructors and 355 students. An annual musical festival is held here under the auspices of the Converse College Choral Society. Four miles south of the city, at Cedar Spring, is the South Carolina Institution for the Education of the Deaf and Blind, founded as a private institution in 1849 and taken over by the state in 1857. There are gold-mines near the city; and Spartanburg county produces large crops of cotton. Cotton mills are the basis of the city's prosperity, and it has also a large wholesale trade, iron-working establishments, and various manufactures. The value of its factory product was $2,127,702 in 1905, or 33·7% more than in 1900. Spartanburg was founded in 1787, and, although railway communication with Columbia and Charleston was opened in 1859, there was little growth until the establishment of the first cotton mill in the vicinity in 1880; it was chartered as a city in this year.

SPEAKER, a title of the presiding officer in the legislatures of various countries. In the English parliament the lord chancellor acts as Speaker of the House of Lords, but should his office be in commission the Crown usually appoints a Speaker to supply his place, a case in point being that of Sir L. Shadwell, vice-chancellor, who in 1835 was appointed Speaker during the time the Great Seal was in commission. Unlike the House of Commons, the Speaker of the House of Lords need not necessarily be a member of the House; Brougham in 1830 sat on the woolsack as Speaker in his capacity of lord chancellor, being then plain Mr Brougham, his patent of nobility not having yet been made out. The House of Lords has also deputy Speakers who are appointed by commission. The duties of the Speaker of the House of Lords are defined by a standing order as follows: "The lord chancellor, when he speaks to the House, is always to speak uncovered, and is not to adjourn the House, or to do anything else as mouth of the House, without the consent of the Lords first had, except the ordinary thing about bills, which are of course, wherein the Lords may likewise overrule; as for preferring one bill before another, and such-like; and in case of difference among the Lords, it is to be put to the question; and if the lord chancellor will speak to anything particularly he is to go to his own place as a peer." The Speaker of the House of Lords, as compared with the Speaker of the House of Commons, is an official without power; even his seat, the woolsack, is technically outside the House. Contrary to the practice in the Commons, he acts as a strong party man, making speeches on behalf of government measures from his place as a peer. Proposals have from time to time been made for augmenting the powers of the Speaker of the House of Lords, but it has been pointed out that, as he is a minister of the Crown, and not chosen by the House itself, and moreover is often the member of the least experience in the House, it would be inexpedient that he should exercise the same powers as the Speaker of the Commons.

The Speaker of the House of Commons is always a member of that House, and though chosen by the members themselves (subject to the approval of the sovereign) from one of the great political parties, he never either votes (except in the case of a tie) or speaks in his capacity as a member during the time he holds office. His duty is to enforce the observance of the rules laid down for preserving order in the proceedings of the House; he puts every question and declares the determination thereon. As "mouth of the House" he communicates its resolutions to others, conveys its thanks, and expresses its censure, its reprimands or its admonitions. He issues warrants for executing the orders of the House, as the commitment of offenders, the issue of writs, the attendance of witnesses or prisoners in custody, &c. The symbol of his authority is the mace, which is borne before him by the serjeant-at-arms when he enters or leaves the House; it reposes on the table when he is in the chair, and it accompanies him on all state occasions. The Speaker takes precedence of all commoners in the kingdom both by ancient custom and by legislative declaration (1 Will. & Mary c. 21). His salary is £5000 a year. It is usual to create a retiring Speaker a peer of the realm, generally with the rank of viscount. The office is of great antiquity, and in the various conflicts between the Commons and the Crown was one of considerable difficulty, especially when, as mouthpiece of the House, he had to read petitions or addresses or deliver in the presence of the sovereign speeches on their behalf. The first to whom the title was definitely given was Sir Thomas Hungerford (d. 1398).

A list of Speakers, most of whom are separately noticed, from 1600 is appended. The date of election is given in brackets:—

J. Croke (1601).
Sir E. Phelips (1604).
Sir R. Crewe (1614).
T. Richardson (1621).
*[1]Sir T. Crewe (1624).
Sir H. Finch (1626).
Sir J. Finch (1628).
J. Glanville (1640).
*[2]W. Lenthall (1640).
H. Pelham (1647).
F. Rous (1653).
Sir T. Widdrington (1656).
C. Chute (1659).
Sir L. Long (1659).
T. Bampfylde (1659).
W. Say (1660).
Sir H. Grimston (1660).
Sir E. Turnour (1661).
Sir J Charlton (1673).
*E. Seymour (1673).
Sir R. Sawyer (1678).
Sir W. Gregory (1679).
*W. Williams (1680).
*[3]Sir J. Trevor (1685).
H. Powle (1689).
P. Foley (1695).
Sir T. Littleton (1698).
*R. Harley (1701) (*Earl of Oxford*).
[4]J. Smith (1705).
Sir R. Onslow (1708).
W. Bromley (1710).
Sir T. Hanmer (1714).
*S. Compton (1715) (*Earl of Wilmington*).
*[5]A. Onslow (1728).
*Sir J. Cust (1761).
*Sir Fletcher Norton (1770) (*Lord Grantly*).
*C. W. Cornwall (1780).
W. W. Grenville (1789) (*Lord Grenville*).
*[6]H. Addington (1789) (*Viscount Sidmouth*).
Sir J. Mitford (1801) (*Lord Redesdale*).
*C. Abbott (1802) (*Lord Colchester*).
*[7]H. C. M. Sutton (1817) (*Viscount Canterbury*).
*J. Abercromby (1835) (*Lord Dunfermline*).
*C. Shaw Lefevre (1841) (*Viscount Eversley*).
*J. E. Denison (1857) (*Viscount Ossington*).
*H. B. Brand (1872) (*Viscount Hampden*).
*A. W. Peel (1884) (*Viscount Peel*).
*W. C. Gully (1895) (*Viscount Selby*).
*J. W. Lowther (1905).

* Speaker in more than one parliament.

The title of Speaker is also applied to the presiding officer of the various legislative assemblies in the British colonies, that of president being applied to the presiding officer of the upper houses, legislative councils as they are usually called. In Canada, however, the presiding officer both of the Senate and the House of Commons is termed Speaker. In the United States the Speaker of the House of Representatives is an officer of considerable power (see UNITED STATES: *Constitution and Government*).

AUTHORITIES.—Stubbs, *Constitutional History*; J. A. Manning, *Lives of the Speakers* (1850); E. Lummis, *The Speaker's Chair*

[1] Brother of Sir R. Crewe.
[2] Speaker of the Long Parliament.
[3] Convicted of bribery and expelled, 1695.
[4] First Speaker of the Commons of Great Britain.
[5] Nephew of Sir R. Onslow, Speaker in 1708 and great-great-great-grandson of R. Onslow, Speaker in the second parliament of Elizabeth. Arthur Onslow was the second Speaker to be elected five times; the first Speaker to be so elected was Thomas Chaucer in the reign of Henry V. Onslow also held the Speakership for the longest period (1727–1761).
[6] Afterwards prime minister. Was first Speaker of the Commons of the United Kingdom.
[7] First to be Speaker six times and seven times.

SPEAR (O. Eng. *spere*, O. H. Ger. *sper*, mod. Ger. *speer*, &c., cf. Lat. *sparus*; probably related to "spar," a beam), a weapon of offence. Developed from a sharp-headed stake, the spear may be reckoned, with the club, as among the most ancient of weapons. All the prehistoric races handled the spear; all savage folk thrust with it or hurl it; civilized man still keeps it as the lance and the boar-spear; indeed, the bayonet is a spear-head with the rifle for a shaft.

The English before the Norman conquest were a spear-bearing race. The freeman's six-foot ashen spear was always near his hand; and its head is found beside the bones of every warrior. The casting javelin was commoner than the bow. Norman horsemen made the long lance, a dozen feet long, its pennon fluttering below the point, the knightly weapon. Throwing spears became rare, the Black Prince's English knights wondering at the Spanish fashion of casting darts. In the 14th century the vamplate came into use as a guard for the lance hand above the grip. At this time also the coronel head was devised for the better safeguard of the jousters, many of whom, however, preferred the blunted or "rebated" point. The next step in development gave the shaft a swell towards the hand on both sides of the grip, a swell exaggerated in the jousting lance of the 16th century, which, fluted and hollowed, is found weighing twenty pounds, with a girth of as much as 27½ in. at its broadest part. Leather "burres" were added below the grip and, before the end of the 14th century, the weight of the jousting lance called for the use of the lance-rest, a hook or catch screwed to the right breast of the harness.

The Scots, always weaker than the English in archery, favoured the long spear as the chief weapon of the infantry, and from Falkirk onwards held their own in their "schiltron" formation against all cavalry, until riddled and disarrayed by the arrow-flights. Their English enemy, when harquebusiers began to oust the archers, exchanged the old bills for those 18 and 20 ft. pikes which bristled from the squares protecting the "shot." At the same time, the English horsemen began to leave the lance for sword, pistol and musketoon. During the civil wars in the 17th century every man on foot was either pikeman or musketeer. After 1675 the long pike gave way to the bayonet in its first shape of a dagger whose hilt could be struck into the muzzle of the musket, and, some fourteen years later, the bayonet with a ring-catch gave the infantryman the last form of his pike. Sergeants, however, carried through the 18th century a "halbert" (*q.v.*) which, in its degenerate form, became a short pike, and infantry officers were sometimes armed with the spontoon. In 1816 certain dragoon regiments were given the lance which had been seen at work in the hands of Poles and Cossacks; and the weapon is still part of the service equipment although controversy is still hot over its value in action, its supporters urging the demoralizing effect of the lance against broken troops. Queen Victoria's navy gave up, in favour of the cutlass bayonet, the pikes which were once served out to repel attacks of boarders. At the present day the High Sheriff's party of javelin-men are the only Englishmen who march on foot with the ancient weapon. (See further LANCE.)

SPECIES, a term, in its general and once familiar significance, applied indiscriminately to animate and inanimate objects and to abstract conceptions or ideas, as denoting a particular phase, or sort, in which anything might appear. In logic it came to be used as the translation of the Gr. εἶδος, and meant a number of individuals having common characters peculiar to them, and so forming a group which with other groups were included in a higher group. The application of the term was purely relative, for the higher group itself might be one of the "species," or modes of a still higher group. In medicine it was used for the constituents of a prescription. In algebra it denoted the characters which represented quantities in an equation.

Early writers on natural history used the term in its vague logical sense without limiting it to a special category in the hierarchy of classification. To John Ray, the famous English naturalist, the credit is generally given of first making species a definite term in zoology and botany, but Ray owed much of his classification to Kaspar or Gaspard Bauhin (1550–1624), professor of Greek and of Anatomy and Botany at Basel, and much of his clear definition of terms to an unpublished MS. of Joachim Jung of Hamburg (1587–1657). Sir W. T. Thisleton Dyer (*Edinburgh Review*, 1902, p. 370) thinks that Ray's use of the word may be traced to the last-mentioned authors. It is clear, however, that through Ray's work in the 17th century the common biological application of species became fixed much in its modern form, as denoting a group of animals or plants capable of interbreeding, and although not necessarily quite identical, with marked common characters. Working on these lines, and attaching special importance to common descent, naturalists applied the term with more and more precision, until Linnaeus, in his *Philosophia botanica*, gave the aphorism, "species tot sunt diversae, quot diversae formae ab initio sunt creatae"—"just so many species are to be reckoned as there were forms created at the beginning." Linnaeus' invention of binomial nomenclature for designating species served systematic biology admirably, but at the same time, by attaching preponderating importance to a particular grade in classification, crystallized the doctrine of fixity. The lower grades in classification such as sub-species and varieties on the one hand, and the higher grades on the other, such as genera and families, were admitted to be human conceptions imposed on the living world, but species were concrete, objective existences to be discovered and named. G. L. L. Buffon and J. P. B. Lamarck practically conceded the objective existence of species in arguing that they might be modified by external conditions, and G. L. Cuvier proclaimed their fixity without reserve. Charles Darwin found the conception of species so definite and fixed that he chose for the title of his great book (1859) the words *On the Origin of Species by Means of Natural Selection*, although his exposition of evolution applied equally to every grade in classification. E. B. Poulton, in an admirable discussion of contemporary views regarding species (presidential address to the Entomological Society of London 1904), has shown that Darwin did not believe in the objective existence of species, not only because he was led to discard the hypothesis of special creation as the explanation of the polymorphism of life, but because in practice as a working systematist he could neither find for himself nor ascertain from other systematists any settled criteria by which a group of specimens could be elevated into a genus, accepted as a species, or regarded as a variety.

The vast advance in knowledge of the existing forms of living things that has been acquired and recorded since 1859 has accentuated the difficulty of finding any morphological criteria for species. A few writers have insisted that they are discontinuous, and that real gaps exist between them. Equally great gaps, however, may exist between males and females, between climatic phases or summer and winter forms. The attempt to find a physiological criterion has similarly failed; many forms that have been universally accepted as true species produce fertile hybrids (see HYBRIDISM). In modern practice (see ZOOLOGICAL NOMENCLATURE) systematists no longer regard species as more than as an artificial rank in classification, to be applied chiefly for reasons of convenience, so that the word is reverting to its older logical significance. The word "species" now signifies a grade or rank in classification assigned by systematists to an assemblage of organic forms which they judge to be more closely interrelated by common descent than they are related to forms judged to be outside the species, and of which the known individuals, if they differ amongst themselves, differ less markedly than they do from those outside the species, or, if differing markedly, are linked by intermediate forms. It is to be noted that the individuals may themselves be judged to fall into groups of minor rank, known as sub-species or local varieties, but such subordinate assemblages are elevated to specific rank, if they appear not to intergrade so as to form a linked species, whilst on the other hand assemblages judged to be species are merged, or degraded to sub-species, if they are found to intergrade by discoveries of linking forms. A species, in short, is a subjective conception, and some writers, as for instance E. Ray Lankester, have urged that the word is so firmly asssociated with historical implications of fixity which are now incongruous with its application, that it ought to be discarded from scientific nomenclature.

In technical biology each species is designated by two words, one for the genus, printed with an initial capital, and one for the particular species, printed without an initial capital in Zoology, whilst in Botany the habit once common to both subjects is retained, and the specific name if derived from a proper name is printed with a capital. The two words are printed in italics, and may be followed by the name of the author who first described the species. Thus "*Canis vulpes* Linnaeus" is the specific designation of the common fox, *Canis* being the generic term common to dogs, wolves and so forth, and *vulpes* indicating the particular species, whilst the attached author's name indicates that Linnaeus first named the species in question. (P. C. M.)

SPECIFICATION (from Med. Lat. *specificatio, specificare*, to enumerate or mention in detail), any detailed statement, especially one on which an estimate or plan is based, as the specification of a builder or architect (see BUILDING). In patent law a specification is a description of an invention. An application for a patent must be accompanied by a specification, either provisional or complete. If a complete specification does not accompany the application, it must be forwarded usually within six months of the date of application, otherwise the application is deemed to be abandoned. A provisional specification declares the nature of the invention in general terms, while a complete specification describes the invention in detail, and shows the manner in which it is to be carried out (see further PATENTS).

In the civil law (see ACCESSION) specification was the working up of a thing into a new product; for example, the making of bread from grain. The effect of specification was that the original owner lost his title in favour of the creator of the new product, but had an action for the value of the materials.

SPECIFIC PERFORMANCE, an equitable doctrine under which a court of equity, in certain exceptional cases where the normal legal remedy, *i.e.* damages, would not be a sufficient compensation, orders from a defaulting party a specific or actual performance of the thing which he had contracted to do. The courts act on their own discretion in affording or refusing the relief of specific performance, and as a general rule will refuse that relief where the common law remedy is adequate, where the court would be unable to superintend or enforce the execution of its judgment, where the plaintiff has himself acted inequitably, or where the enforcement of specific performance would be unreasonable. Specific performance is usually confined to executory agreements, such as a conveyance or a lease of land; it is not usually enforced in the cases of personal acts or in those of contracts for personal service. In the case of a contract for the sale of a chattel the courts will only order specific performance when the chattel is of peculiar value to the purchaser and cannot be obtained elsewhere. The courts are guided considerably by precedent, and it is only by reference to a standard textbook that details can be obtained of the conditions and restrictions which hedge the jurisdiction of the courts. In Scots law specific performance, or "implement," is part of the ordinary jurisdiction of the courts.

See Fry on *Specific Performance*; *Ency. English Law*, tit. "Specific Performance"; and Story, *Equity Jurisprudence*.

SPECTACLES, the name given to flat glasses, prisms, spherical or cylindrical lenses, mechanically adjusted to the human eyes, so as to correct defects of vision (*q.v.*). They are made usually of crown glass or rock crystal ("pebbles"), the latter being somewhat lighter and cooler to wear. They are mounted in rigid steel wire or gold frames, with fastening-pieces over the ears; single or double eye-glasses, and hand-glasses, or lorgnettes, being varieties of form, according to the circumstances and the wearer's taste.

Preserves.—Preserves are used to conceal deformities or to protect the eyes in the many conditions where they cannot tolerate bright light, such as ulceration and inflammation of the cornea, certain diseases of the iris, ciliary body, choroid, and retina. They are made of bluish, "smoked," or almost black coloured glass, and are of very various shapes, according to the amount of obscuration necessary.

Prisms.—Prisms are of great value in cases of double vision due to a slight tendency to squinting, caused by weakness or over-action of the muscular apparatus of the eyeball. Prisms deflect rays of light towards their bases. Hence, if a prism is placed in front of the eye with its base towards the nose, a ray of light falling upon it will be bent inwards, and seem to come from a point farther out from the axis of vision. Conversely, if the base of the prism is turned towards the temple, the ray of light will seem to come from a point nearer the axis, and will induce the eye to turn inwards, to converge towards its fellow. In cases of myopia or short-sight owing to weakness of the internal recti muscles, the eyes in looking at a near object, instead of converging, tend to turn outwards, and so double vision results. If a suitable prism is placed in front of the eyes the double vision may be prevented. These prisms may be combined with concave lenses, which correct the myopia, or, since a concave lens may be considered as composed of two prisms united at their apices, the same effect may be obtained by making the distance between the centres of the concave lenses greater than that between the centres of the pupils. Again, to obviate the necessity for excessive convergence of the eyes so common in hypermetropia, the centre of the pupil should be placed outside the centre of the corrective convex lenses; these will then act as prisms with their bases inwards. Where, on the other hand, there is no tendency to squinting, care must be taken in selecting spectacles that the distances between the centres of the glasses and the centres of the pupils are quite equal, otherwise squinting, or at any rate great fatigue, of the eyes may be induced.

Spherical Lenses.—Biconcave, biconvex and concavo-convex (meniscus) lenses are employed in ophthalmic practice in the treatment of errors of refraction. Until recently these spherical lenses were numbered in terms of their focal length, the inch being used as the unit. Owing principally to differences in the length of the inch in various countries this method had great inconveniences, and now the unit is the refractive power of a lens whose focal length is one metre. This unit is called a "dioptric" (usually written "D"). A lens of twice its strength has a refractive power of 2 D, and a focal length of half a metre, and so on.

Concave Lenses are used in the treatment of myopia or short-sight. In this condition the eye is elongated from before backwards, so that the retina lies behind the principal focus. All objects, therefore, which lie beyond a certain point (the conjugate focus of the dioptric system of the eye, the far point) are indistinctly seen; rays from them have not the necessary divergence to be focused in the retina, but may obtain it by the interposition of suitable concave lenses. Concave lenses should never be used for work within the far point; but they may be used in all cases to improve distant vision, and in very short-sighted persons to remove the far point so as to enable fine work such as sewing or reading to be done at a convenient distance. The weakest pair of concave lenses with which one can read clearly test types at a distance of 18 ft. is the measure of the amount of myopia, and this fully correcting glass may be worn in the slighter forms of short-sight. In higher degrees, where full correction might increase the myopia by inducing a strain of the accommodation, somewhat weaker glasses should be used for near work. In the highest degrees the complete correction may be employed, but lorgnettes are generally preferred, as they can be removed when the eyes become fatigued. It must be remembered that short-sight tends to increase during the early, especially the school, years of life, and that hygienic treatment, good light, good type, and avoidance of stooping are important for its prevention.

Convex Lenses.—In hypermetropia the retina is in front of the principal focus of the eye. Hence in its condition of repose such an eye cannot distinctly see parallel rays from a distance and, still less, divergent rays from a near object. The defect may be overcome more or less completely by the use of the accommodation. In the slighter forms no inconvenience may result; but in higher degrees prolonged work is apt to give rise to aching and watering of the eyes, headache, inability to read or sew for any length of time, and even to double vision and internal strabismus. Such cases should be treated with convex lenses, which should be theoretically of such a strength as to fully correct the hypermetropia. Practically it is found that a certain amount of hypermetropia remains latent, owing to spasm of the accommodation, which relaxes only gradually. At first glasses may be given of such a strength as to relieve the troublesome symptoms; and the strength may be gradually increased till the total hypermetropia is corrected. Young adults with slighter forms of hypermetropia need glasses only for near work; elderly people should have one pair of weak glasses for distant and another stronger pair for near vision. These may be conveniently combined, as in Franklin glasses, where the upper half of the spectacle frame contains a weak lens, and the lower half, through which the eye looks when reading, a stronger one.

Anisometropia.—It is difficult to lay down rules for the treatment of cases where the refraction of the two eyes is unequal. If only one eye is used, its anomaly should be alone corrected; where both are used and nearly of equal strength, correction of each often gives satisfactory results.

Presbyopia.—When distant vision remains unaltered, but, owing to gradual failure of the accommodative apparatus of the eye clear vision within 8 in. becomes impossible, convex lenses should be used for reading of such a strength as to enable the eye to see clearly about 8 in. distance. Presbyopia is arbitrarily said to commence at the age of forty, because it is then that the need of spectacles for reading is generally felt; but it appears later in myopia and earlier in hypermetropia. It advances with years, requiring from time to time spectacles of increasing strength.

Cylindrical Lenses.—In astigmatism, owing to differences in the refractive power of the various meridians of the eye, great defect of sight, frequently accompanied by severe headache, occurs. This condition may be cured completely, or greatly improved, by the use of lenses whose surfaces are segments of cylinders. They may be used either alone or in combination with spherical lenses. The correction of astigmatism is in many cases a matter of considerable difficulty, but the results to vision almost always reward the trouble.

Convex spectacles were invented (see LIGHT) towards the end of the 13th century, perhaps by Roger Bacon. Concave glasses were introduced soon afterwards. Sir G. B. Airy, the astronomer, about 1827, corrected his own astigmatism by means of a cylindrical lens. Periscopic glasses were introduced by Dr W. H. Wollaston.

SPECTROHELIOGRAPH, an instrument for photographing the sun with monochromatic light. In its simplest form it consists of a direct-vision spectroscope, having an adjustable slit (called "camera slit"), instead of an eyepiece, in the focal plane of the observing telescope. This slit is set in such a position as to transmit a single line of the spectrum, *e.g.* the K line of calcium. Suppose a fixed image of the sun to be formed on the collimator slit of this spectroscope, and a photographic plate, with its plane parallel to the plane of the solar image, to be mounted almost in contact with the camera slit. The spectroscope is then moved parallel to itself, admitting to the collimator slit light from all parts of the sun's disk. Thus a monochromatic image of the sun, formed of a great number of successive images of the spectral line employed, will be built up on the plate. As the only light permitted to reach the plate is that of the calcium line, the resulting image will represent the distribution of calcium vapour in the sun's atmosphere. The calcium clouds or *flocculi* thus recorded are invisible to the eye, and are not shown on direct solar photographs taken in the ordinary way.

The calcium flocculi, on account of the brilliant reversals of the H and K lines to which they give rise, and the protection to the plate afforded by the diffuse dark bands in which these bright lines occur, are easily photographed with a spectroheliograph of low dispersion. In the case of narrower lines, however, higher dispersion is required to prevent the light of the continuous spectrum on either side of the dark line from blotting out the monochromatic image. A spectroheliograph which gives excellent results with the lines of calcium, hydrogen and iron is shown in the figure. This instrument, used since 1905 in conjunction with the Snow (horizontal) telescope of the Mount Wilson Solar Observatory, was constructed in the observatory instrument shop in Pasadena.

It consists of a heavy cast-iron platform (*a*) mounted on four steel balls (*b*) which run in V guides of hardened steel. Most of the weight of the instrument is floated on mercury contained in three troughs (*c*, *c*, *c*) which form part of the cast-iron base. The platform carries the two slits, the collimator and camera objectives and the prism-train. An image of the sun, about 6·7 in. in diameter, is formed by the Snow telescope on the collimator slit (*d*). This slit is long enough (8½ in.) to extend entirely across the solar image and across such prominences of ordinary height as may happen to lie at the extremities of a vertical diameter. After passing through the slit the diverging rays fall upon the 8 in. collimator objective (*e*), which is constructed in the manner of a portrait lens in order to give a sharp field of sufficient diameter to include the entire solar image. In the Snow telescope the ratio of aperture to focal length is 1 : 30. Hence light from any point on the slit will fill a circle about 2 in. in diameter on the collimator objective, as its focal length is 60 in. Since the diameter of the solar image is 6·7 in. there is a slight, but inappreciable loss of light from points in the image at the extremities of a vertical diameter.

The rays, rendered parallel by the collimator objective, meet a plane mirror (*f*) of silvered glass, which reflects them to the prisms (*g*, *g'*). These are of dense flint-glass (Schott 0·102), and each has a refracting angle of 63° 29'. Their width and height are sufficient to transmit (at the position of minimum deviation) the entire beam received from the collimator. After being deviated 180° from the original direction, the dispersed rays fall on the camera objective (*h*), which is exactly similar to the collimator objective. This forms an image of the solar spectrum in its focal plane on the camera slit (*i*). Beyond the camera slit, and almost in contact with it, the photographic plate-carrier (*j*) is mounted on a fixed support. In order to bring a spectral line upon the camera slit, the slit is widely opened and the plane mirror (*f*) rotated until the line is seen. A cross-hair, in the focal plane of an eyepiece, is then moved horizontally until it coincides with the line in question. The slit is narrowed down to the desired width, and moved as a whole by a micrometer screw, until it coincides with the cross-hair. The eyepiece is removed and the photographic plate (*k*) placed in position. An electric motor, belted to a screw (*l* or *l'*) connected with the spectroheliograph, is then started.[1] The screw moves the spectroheliograph at a perfectly uniform rate across the fixed solar image. Thus a monochromatic image of the sun is built up on the fixed photographic plate.

The spectroheliograph, originally designed for photographing the solar prominences, disclosed in its first application at the Kenwood Observatory (Chicago, 1892) a new and unexplored region of the sun's atmosphere. Photographs of the solar disk, taken with the H or K line, show extensive luminous clouds (flocculi) of calcium vapour, vastly greater in area than the sun-spots. By setting the camera slit so as to admit to the photographic plate the light of the denser calcium vapour, which lies at low levels, or that of the rarer vapour at high levels, the phenomena of various superposed regions of the atmosphere can be recorded. The lower and denser vapour appears as bright clouds, but the cooler vapour, at higher levels, absorbs the light from below and thus gives rise to dark clouds.

The first photographs of the sun in hydrogen light were made with the spectroheliograph in 1903. These reveal dark hydrogen flocculi, which appear to lie at a level above that of the bright calcium flocculi. They also show less extensive bright flocculi, usually in the immediate neighbourhood of sunspots, and frequently eruptive in character. These rise

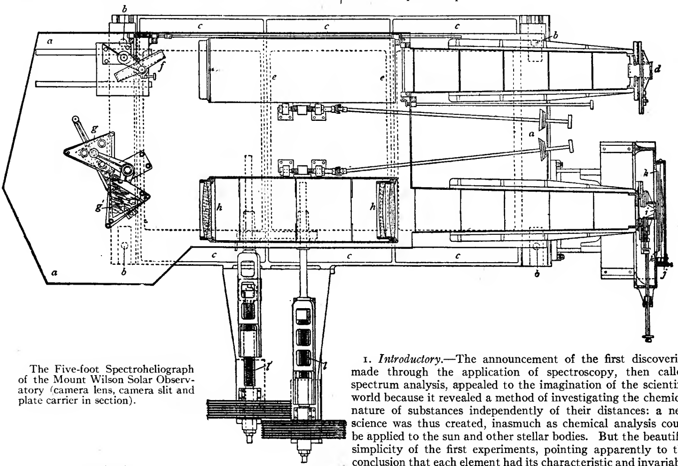
[1] Two screws, of different pitch, are provided, to give different speeds.

(*By permission of the Carnegie Institution of* **Washington.**)

THE SUN, 7TH OCTOBER 1908. Showing right and left-hand Sun-spot vortices.

from a low level, and sometimes reach considerable elevations in the form of eruptive prominences.

In such an exploration of the sun's atmosphere it might be anticipated that definite currents, or some evidences of atmospheric circulation analogous to those familiar in terrestrial meteorology, would be discovered. Neither the forms nor the motions of the calcium flocculi revealed the existence of such



The Five-foot Spectroheliograph of the Mount Wilson Solar Observatory (camera lens, camera slit and plate carrier in section).

currents, but in the higher region shown by the hydrogen photographs the distribution of the dark flocculi suggested the operation of definite forces, though their nature remained obscure until the spring of 1908. At that time monochromatic photographs of the sun were first made on Mount Wilson with the red (Hα) line of hydrogen, previous hydrogen photographs having been taken with Hβ, Hγ or Hδ in the blue or violet. On account of the relatively great strength of Hα at a considerable distance from the photosphere, the new photographs recorded flocculi at high levels previously unexplored. The forms of these flocculi show that all sun-spots are vortical in nature, and are probably analogous to terrestrial cyclones or tornadoes. Most of the solar vortices indicate clockwise rotation in the southern hemisphere and counter-clockwise rotation in the northern, as in the case of terrestrial cyclones. But frequent exceptions have been observed in which the direction of rotation is reversed. The study of these vortices has led to the discovery of a magnetic field in sun-spots, apparently caused by electric convection in the vortices.

It is evident that by the use of a spectroheliograph of sufficiently high dispersion, photographs may be taken of vapours in the sun represented by lines narrower than those of calcium and hydrogen. Such work has been in progress both at Mount Wilson and at Meudon, and the erection of a spectroheliograph of 75 ft. focal length on Mount Wilson was at the end of 1908 contemplated for an early date.

Descriptions of spectroheliographs by Hale, Deslandres, Newall and others, may be found in various papers in *Astronomy and Astrophysics*, *Astrophysical Journal*, *Comptes rendus*, *Bulletin astronomique*, and other periodicals. (G. E. H.)

SPECTROSCOPY (from Lat. *spectrum*, an appearance, and Gr. *σκοπεῖν*, to see), that branch of physical science which has for its province the investigation of spectra, which may, for our present purpose, be regarded as the product of the resolution of composite luminous radiations into more homogeneous components. The instruments which effect such a resolution are called spectroscopes.

1. *Introductory*.—The announcement of the first discoveries made through the application of spectroscopy, then called spectrum analysis, appealed to the imagination of the scientific world because it revealed a method of investigating the chemical nature of substances independently of their distances: a new science was thus created, inasmuch as chemical analysis could be applied to the sun and other stellar bodies. But the beautiful simplicity of the first experiments, pointing apparently to the conclusion that each element had its characteristic and invariable spectrum whether in the free state or when combined with other bodies, was soon found to be affected by complications which all the subsequent years of study have not completely resolved. Compound bodies, we now know, have their own spectra, and only when dissociation occurs can the compound show the rays characteristic of the element: this perhaps was to be expected, but it came as a surprise and was not readily believed, that elements, as a rule, possess more than one spectrum according to the physical conditions under which they become luminous. Spectrum analysis thus passed quickly out of the stage in which its main purpose was "analysis" and became our most delicate and powerful method of investigating molecular properties; the old name being no longer appropriate, we now speak of the science of "Spectroscopy."[1] Within the limit of this article it is not possible to give a complete account of this most intricate branch of physics; the writer therefore confines himself to a summary of the problems which now engage scientific attention, referring the reader for details to H. Kayser's excellent and complete *Handbuch der Spectroscopie*.

2. *Instrumental*.—The spectroscope is an instrument which allows us to examine the vibrations sent out by a radiating source: it separates the component parts if they are homogeneous, *i.e.* of definite periodicity, and then also gives us the distribution of intensity along the homogeneous constituents. This resolution into simple periodic waves is arbitrary in the same sense as is the decomposition of forces along assumed

[1] The present writer believes that he was the first to introduce the word "Spectroscopy" in a lecture delivered at the Royal Institution in 1882 (*Proceedings*, vol. ix.).

axes; but, in the same way also the results are correct if the resolution is treated as an analytical device and in the final result account is taken of all the overlapping components. Spectroscopes generally consist of three parts: (1) the collimator; (2) the analysing appliance, (3) the telescope. The slit of the collimator confines the light to a nearly linear source, the beam diverging from each point of the source being subsequently made parallel by means of a lens. The parallelism, which is required to avoid aberrations, otherwise introduced by the prism or grating, may often be omitted in instruments of small power. The lens may then be also dispensed with, and the whole collimator becomes unnecessary if the luminous source is narrow and at a great distance, as for instance in the case of the crescent of the sun near the second and third contact of a total solar eclipse. The telescope serves to examine the image of the slit and to measure the angular separation of the different slit images; when photographic methods are employed the telescope is replaced by a camera.

The analysing appliance constitutes the main feature of a spectroscope. It may consist of one of the following:—

a. A prism or a train of prisms. These are employed in instruments of small power, especially when luminosity is a consideration; but their advantage in this respect is to a great extent lost, when, in order to secure increased resolving power, the size of the prisms, or their number, is unduly increased.

b. A grating. Through H. A. Rowland's efforts the construction of gratings has been improved to such an extent that their use is becoming universal whenever great power or accuracy is required. By introducing the concave grating which (see Diffraction of Light, § 8) allows us to dispense with all lenses, Rowland produced a revolution in spectroscopic measurement. At present we have still to content ourselves with a much diminished intensity of light when working with gratings, but there is some hope that the efforts to concentrate the light into one spectrum will soon be successful.

c. An échelon grating. Imagine a horizontal section of a beam of light, and this section divided into a number of equal parts. Let somehow or other retardations be introduced so that the optical length of the successive parts increases by the same quantity $n\lambda$, n being some number and λ the wave-length. If on emergence the different portions he brought together at the focus it is obvious that the optical action must be in every respect similar to that of a grating when the nth order of spectrum is considered. A. Michelson produced the successive retardations by inserting step-by-step plates of glass of equal thickness so that the different portions of the beam traversed thicknesses of glass equal to $n\lambda$, $2n\lambda$, $3n\lambda$, . . . $N\lambda$. The optical effect as regards resolving power is the same as with a grating of N lines in the nth order, but, nearly all the light not absorbed by the glass may be concentrated in one or two orders.[1]

d. Some other appliance in which interference with long difference of path is made use of, such as the interferometer of Fabry and Perot, or Lummer's plate (see Interference of Light).

The échelon and interferometer serve only a limited purpose, but must be called into action when the detailed structure of lines is to be examined. For the study of Zeeman effects (see Magneto-Optics) the échelon seems specially adapted, while the great pliability of Fabry and Perot's methods, allowing a clear interpretation of results, is likely to secure them permanently an established place in measurements of precision.

The power of a spectroscope to perform its main function, which is to separate vibrations of different but closely adjacent frequencies, is called its "resolving power." The limitation of power is introduced as in all optical instruments, by the finiteness of the length of a wave of light which causes the image of an indefinitely narrow slit to spread out over a finite width in the focal plane of the observing telescope. The so-called "diffraction" image of a homogeneously illuminated slit shows a central band limited on either side by a line along which the intensity is zero, and this band is accompanied by a number of fainter images corresponding to the diffraction of a star image in a telescope. Lord Rayleigh, to whom we owe the first general discussion of the theory of the spectroscope, found by observation that if two spectroscopic lines of frequencies n_1 and n_2 are observed in an instrument, they are just seen as two separate lines when the centre of the central diffraction band of one coincides with the first minimum intensity of the other. In that case the image of the double line shows a diminution of intensity along the centre, just sufficient to give a clear impression that we are not dealing with a single line, and the intensity at the minimum is 0·81 of that at the point of maximum illumination. We may say therefore that if the difference between the frequencies n_1 and n_2 of the two waves is such that in the combined image of the slit the intensity at the minimum between the two maxima falls to 0·81, the lines are just resolved and $n_1/(n_1-n_2)$ may then be called the resolving power. There is something arbitrary in this definition, but as the practical importance of the question lies in the comparison between instruments of different types, the exact standard adopted is of minor importance, the chief consideration being simplicity of application. Lord Rayleigh's expression for the resolving power of different instruments is based on the assumption that the geometrical image of the slit is narrow compared with the width of the diffraction image. This condition is necessary if the full power of the instrument is to be called into action. Unfortunately considerations of luminosity compel the observer often to widen the slit much beyond the range within which the theoretical value of resolving power holds in practice. The extension of the investigation to wide slits was first made by the present writer in the article "Spectroscopy" in the 9th edition of the *Encyclopaedia Britannica*. Reconsideration of the subject led him afterwards to modify his views to some extent, and he has since more fully discussed the question.[2] Basing the investigation on the same criterion of resolution as in the case of narrow slits, we postulate for both narrow and wide slits that two lines are resolved when the intensity of the combined image falls to a value of 0·810 in the centre between the lines, the intensity at the maxima being unity. We must now however introduce a new criterion the "purity" and distinguish it from the resolving power: the purity is defined by $n_1/(n_1-n_2)$, where n_1 and n_2 are the frequencies of two lines such that they would just be resolved with the width of slit used. With an indefinitely narrow slit the purity is equal to the resolving power. As purity and resolving power are essentially positive quantities, n_1 in the above expression must be the greater of the two frequencies. With wide slits the difference n_1-n_2 depends on their width. If we write $P=p\,R$ where P denotes the purity and R the resolving power, we may call p the "purity-factor." In the paper quoted the numerical values of p are given for different widths of slit, and a table shows to what extent the loss of purity due to a widening of the slit is accompanied by a gain in luminosity. The general results may be summarized as follows: if the width of the slit is equal to $f\lambda/4D$ (where λ is the wave-length concerned, D the diameter of the collimator lens, and f its focal length) practically full resolving power is obtained and a further narrowing of the slit would lead to loss of light without corresponding gain. We call a slit of this width a "normal slit." With a slit width equal to twice the normal one we lose 6% of resolution, but obtain twice the intensity of light. With a slit equal in width to eight times the normal one the purity is reduced to 0·45R, so that we lose rather more tban half the resolving power and increase the light 3·7 times. If we widen the slit still further rapid loss of purity results, with very little gain in light, the maximum luminosity obtainable with an indefinitely wide slit being four times that obtained with the normal one. It follows that for observations in which light is a consideration spectroscopes should be used which give about twice the resolving power of that actually required; we may then use a slit having a width of nearly eight times that of the normal one.

[2] *Astrophys. Journ.* (1905), 21, p. 197.

Theoretical resolving power can only be obtained when the whole collimator is filled with light and further (as pointed out by Lord Rayleigh in the course of discussion during a meeting of the "Optical Convention" in London, 1905) each portion of the collimator must be illuminated by each portion of the luminous source. These conditions may be generally satisfied by projecting the image of the source on the slit with a lens of sufficient aperture. When the slit is narrow light is lost through diffraction unless the angular aperture of this condensing lens, as viewed from the slit, is considerably greater than that of the collimator lens.

When spectroscopes are used for stellar purposes further considerations have to be taken account of in their construction; and these are discussed in a paper by H. F. Newall.[1]

3. *Spectroscopic Measurements and Standards of Wave-Length.*—All spectroscopic measurement should be reduced to wave-lengths or wave-frequencies, by a process of interpolation between lines the wave-lengths of which are known with sufficient accuracy. The most convenient unit is that adopted by the International Union of Solar Research and is called an Ångström (Å); and is equal to 10^{-8} cms. A. Perot and C. Fabry, employing their interferometer methods, have compared the wave-length of the red cadmium line with the standard metre in Paris and found it to be equal to 6438·4696 Å, the observations being taken in dry air at 18° C and at a pressure of 76 cms. ($g = 980{\cdot}665$). This number agrees singularly well with that determined in 1893 by Michelson, who found for the same line 6438·4700. Perot's number is now definitely adopted to define the Ångström, and need never be altered, for should at some future time further researches reveal a minute error, it will be only necessary to change slightly the temperature or pressure of the air in which the wave-length is measured. A number of secondary standards separated by about 50 Å, and tertiary standards at intervals of from 5 to 10 Å have also been determined. By means of these, spectroscopists are enabled to measure by interpolation the wave-length of any line they may wish to determine. Interpolation is easy in the case of all observations taken with a grating. In the case of a prism some caution is necessary unless the standards used are very close together. The most convenient and accurate formula of interpolation seems to be that discovered by J. F. Hartmann. If D is the measured deviation of a ray, and D_0, λ_0, c and α are four constants, the equation

$$\lambda = \lambda_0 + \frac{c}{(D - D_0)^{1/\alpha}}$$

seems to represent the connexion between deviation and wave-length with considerable accuracy for prisms constructed with the ordinary media.

The constant α has the same value 1·2 for crown and flint glass, so that there are only three disposable constants left. In many cases it is sufficient to substitute unity for α and write

$$\lambda = \lambda_0 + \frac{c}{D - D_0},$$

which gives a convenient formula, which in this form was first used by A. Cornu. If within the range 5100–3700 Å, the constants are determined once for all, the formula seems capable of giving by interpolation results accurate to 0·2 Å, but as a rule the range to which the formula is applied will be much less with a corresponding gain in the accuracy of the results.

Every observer should not only record the resolving power of the instrument he uses, but also the purity-factor as defined above. The resolving power in the case of gratings is simply mn, where m is the order of spectrum used, and n the total number of lines ruled on the grating. In the case of prisms the resolving power is $-t\ (d\mu/d\lambda)$, where t is the effective thickness of the medium traversed by the ray. If t_2 and t_1 are thicknesses traversed by the extreme rays, $t = t_2 - t_1$, and if, as is usually the case, the prism is filled right up to its refraction cap, $t_1 = 0$, and t becomes equal to the greatest thickness of the medium which is made use of. When compound prisms are used in which, for the purpose of obtaining smaller deviation, one part of the compound acts in opposition to the other, the resolving power of the opposing portion must be deducted in calculating the power of the whole. Opticians should supply sufficient information of the dispersive properties of their materials to allow $d\mu/d\lambda$ to be calculated easily for different parts of the spectrum.

[1] *Monthly Notices R.A.S.* (1905), 65, p. 605.

The determination of the purity-factor requires the measurement of the width of the slit. This is best obtained by optical means. The collimator of a spectroscope should be detached, or moved so as to admit of the introduction of an auxiliary slit at a distance from the collimator lens equal to its focal length. If a source of light be placed behind the auxiliary slit a parallel beam of light will pass within the collimator and fall on the slit the width of which is to be measured. With fairly homogeneous light the diffraction pattern may be observed at a distance, varying with the width of the slit from about the length of the collimator to one quarter of that length. From the measured distances of the diffraction bands the width of the slit may be easily deduced.

4. *Methods of Observation and Range of Wave-Lengths.*—Visual observation is limited to the range of frequencies to which our eyes are sensitive. Defining oscillation as is usual in spectroscopic measurement by wave-length, the visible spectrum is found to extend from about 7700 to 3900 Å. In importance next to visual observation, and in the opinion of some, surpassing it, is the photographic method. We are enabled by means of it to extend materially the range of our observation, especially if the ordinary kinds of glass, which strongly absorb ultra-violet light, are avoided, and, when necessary, replaced by quartz. It is in this manner easy to reach a wave-length of 3000 Å, and, with certain precautions, 1800 Å. At that point, however, quartz and even atmospheric air become strongly absorbent and the expensive fluorspar becomes the only medium that can be used. Hydrogen still remains transparent. The beautiful researches of V. Schumann[2] have shown, however, that with the help of spectroscopes void of air and specially prepared photographic plates, spectra can be registered as far down as 1200 Å. Lyman more recently has been able to obtain photographs as far down as 1030 Å with the help of a concave grating placed in vacuo.[3] Although the vibrations in the infra-red have a considerably greater intensity, they are more difficult to register than those in the ultra-violet. Photographic methods have been employed successfully by Sir W. Abney as far as 20,000 Å, but long exposures are necessary. Bolometric methods may be used with facility and advantage in the investigation of the distribution of intensities in continuous or semi-continuous spectra but difficulties are met with in the case of line spectra. Good results in this respect have been obtained by B. W. Snow[4] and by E. P. Lewis,[5] lines as far as 11,500 having been measured by the latter. More recently F. Paschen[6] has further extended the method and added a number of infra-red lines to the spectra of helium, argon, oxygen and other elements. In the case of helium one line was found with a wave-length of 20,582 Å. C. V. Boys' microradiometer has occasionally been made use of, and the extreme sensitiveness of the Crookes' radiometer has also given excellent results in the hands of H. Rubens and E. F. Nichols. In the opinion of the writer the latter instrument will ultimately replace the bolometer, its only disadvantage being that the radiations have to traverse the side of a vessel, and are therefore subject to absorption. In order to record line spectra it is by no means necessary that the receiving instrument (bolometer or radiometer) should be linear in shape, for the separation of adjacent lines may be obtained if the linear receiver be replaced by a narrow slit in a screen placed at the focus of the condensing lens. The sensitive vane or strip may then be placed behind the slit; its width will not affect the resolving power though there may be a diminution of sensitiveness. The longest waves

observed up to the present are those recorded by H. Rubens and E. Aschkinass[1] (·0061 cms. or 610,000 Å).

5. *Methods of Rendering Gases Luminous.*—The extreme flexibility of the phenomena shown by radiating gases renders it a matter of great importance to examine them under all possible conditions of luminosity. Gases, like atmospheric air, hydrogen or carbon dioxide do not become luminous if they are placed in tubes, even when heated up far beyond white heat as in the electric furnace. This need not necessarily be interpreted as indicating the impossibility of rendering gases luminous by temperature only, for the transparency of the gas for luminous radiations may be such that the emission is too weak to be detected. When there is appreciable absorption as in the case of the vapours of chlorine, bromine, iodine, sulphur, selenium and arsenic, luminosity begins at a red heat. Thus G. Salet[2] observed that iodine gives a spectrum of bright bands when in contact with a platinum spiral made white hot by an electric current, and J. Evershed[3] has shown that in this and other cases the temperature at which emission becomes appreciable is about 700°. It is only recently that owing to the introduction of carbon tubes heated electrically the excitement of the luminous vibrations of molecules by temperature alone has become an effective method for the study of their spectra even in the case of metals. Hitherto we were entirely and still are generally confined to electrical excitation or to chemical action as in the case of flames.

In the ordinary laboratory the Bunsen flame has become universal, and a number of substances, such as the salts of the alkalis and alkaline earths, show characteristic spectra when suitably placed in it. More information may be gained with the help of the oxyhydrogen flame, which with its higher temperature has not been used as frequently as it might have been, but W. N. Hartley has employed it with great success, and in cyanite (a silicate of aluminium) has found a material which is infusible at the temperature of this flame, and is therefore suitable to hold the substance which it is desired to examine. An interesting and instructive manner of introducing salts into flames was discovered by A. Gouy, who forced the air before it entered the Bunsen burner, through a spray produce containing a salt in solution. By this method even such metals as iron and copper may be made to show some of their characteristic lines in the Bunsen burner. The spectra produced under these circumstances have been studied in detail by C. de Watteville.[4]

Of more frequent use have been electric methods, owing to the greater intensity of the radiations which they yield. Especially when large gratings are employed do we find that the electric arc alone seems sufficient to give vibrations of the requisite power. The metals may be introduced into the arc in various ways, and in some cases where they can be obtained in sufficient quantity the metallic electrodes may be used in the place of carbon poles.

The usual method of obtaining spectra by the discharges from a Ruhmkorff coil or Wimshurst machine needs no description. The effects may be varied by altering the capacity and self-induction of the circuit which contains the spark gap. The insertion of self-induction has the advantage of avoiding the lines due to the gas through which the spark is taken, but it introduces other changes in the nature of the spark, so that the results obtained with and without self-induction are not directly comparable. Count Gramont[5] has been able to obtain spectroscopic evidence of the metalloids in a *mineral* by employing powerful condensers and heating the electrodes in an oxyhydrogen flame when these (as is often the case) are not sufficiently conducting.

When the substance to be examined spectroscopically is in solution the spark may be taken from the solution, which must then be used as kathode of air. The condenser is in this case not necessary, in fact better results are obtained without it. Lecoq de Boisbaudran has applied this method with considerable success, and it is to be recommended whenever only small electric power is at the disposal of the observer. To diminish the resistance the current should pass through as small a layer of liquid as possible. It is convenient to place the liquid in a short tube, a platinum wire sealed in at the bottom to convey the current reaching to the level of the open end. If a thick-walled capillary tube is passed over the platinum tube and its length so adjusted that the liquid rises in it by capillary action just above the level of the tube, the spectrum may be examined directly, and the loss of light due to the passage through the partially wetted surface of the walls of the tube is avoided.

For the investigation of the spectra of gases at reduced pressures the so-called Plücker tubes (more generally but incorrectly called Geissler tubes) are in common use. When the pressure becomes very low, inconvenience arises owing to the difficulty of establishing the discharge. In that case the method introduced by J. J. Thomson might with advantage be more frequently employed. Thomson[6] places spherical bulbs inside thick spiral conductors through which the oscillating discharge of a powerful battery is led. The rapid variation in the intensity of the magnetic field causes a brilliant electrodeless discharge which is seen in the form of a ring passing near the inner walls of the bulb when the pressure is properly adjusted. A variety of methods to render gases luminous should be at the command of the investigator, for nearly all show some distinctive peculiarity and any new modification generally results in fresh facts being brought to light. Thus E. Goldstein[7] was able to show that an increase in the current density is capable of destroying the well-known spectra of the alkali metals, replacing them by quite a new set of lines.

6. *Theory of Radiation.*—The general recognition of spectrum analysis as a method of physical and chemical research occurred simultaneously with the theoretical foundation of the connexion between radiation and absorption. Though the experimental and theoretical developments were not necessarily dependent on each other, and by far the larger proportion of the subject which we now term "Spectroscopy" could stand irrespective of Gustav Kirchhoff's thermodynamical investigations, there is no doubt that the latter was, historically speaking, the immediate cause of the feeling of confidence with which the new branch of science was received, for nothing impresses the scientific world more strongly than just that little touch of mystery which attaches to a mathematical investigation which can only be understood by the few, and is taken on trust by the many, provided that the author is a man who commands general confidence. While Balfour Stewart's work on the theory of exchanges was too easily understood and therefore too easily ignored, the weak points in Kirchhoff's developments are only now beginning to be perceived. The investigations both of Balfour Stewart and of Kirchhoff are based on the idea of an enclosure at uniform temperature and the general results of the reasoning centre in the conclusion that the introduction of any body at the same temperature as the enclosure can make no difference to the streams of radiant energy which we imagine to traverse the enclosure. This result, which, accepting the possibility of having an absolutely opaque enclosure of uniform temperature, was clearly proved by Balfour Stewart for the total radiation, was further extended by Kirchhoff, who applied it (though not with mathematical rigidity as is sometimes supposed) to the separate wave-lengths. All Kirchhoff's further conclusions are based on the assumption that the radiation transmitted through a partially transparent body can be expressed in terms of two independent factors (1) an absorption of the incident radiation, and (2) the radiation of the absorbing medium, which takes place equally in all directions. It is assumed further that the absorption is proportional to the incident radiation and (at any rate approximately) independent of the temperature, while the radiation is assumed to be a function of the temperature

only and independent of the temperature of the enclosure. This division into absorption and radiation is to some extent artificial and will have to be revised when the ohenomena of radiation are placed on a mechanical basis. For our present purpose it is only necessary to point out the difficulty involved in the assumption that the radiation of a body is independent of the temperature of the enclosure. The present writer drew attention to this difficulty as far back as 1881,[1] when he pointed out that the different intensities of different spectral lines need not involve the consequence that in an enclosure of uniform temperature the energy is unequally partitioned between the corresponding degrees of freedom. When the molecule is losing energy the intensity of each kind of radiation depends principally on the rapidity with which it can be renewed by molecular impacts. The unequal intensities observed indicate a difference in the effectiveness of the channels through which energy is lost, and this need not be connected with the ultimate state of equilibrium when the body is kept at a uniform temperature. For our immediate purpose these considerations are of importance inasmuch as they bear on the question how far the spectra emitted by gases are thermal effects only. We generally observe spectra under conditions in which dissipation of energy takes place, and it is not obvious that we possess a definition of temperature which is strictly applicable to these cases. When, for instance, we observe the relation of the gas contained in a Plücker tube through which an electric discharge is passing, there can be little doubt that the partition ot energy is very different from what it would be in thermal equilibrium. In consequence the question as to the connexion of the spectrum with the temperature of the gas seems to the present writer to lose some of its force. We might define temperature in the case of a flame or vacuum tube by the temperature which a small totally reflecting body would tend to take up if placed at the spot, but this definition would fail in the case of a spark discharge. Adopting the definition we should have no difficulty in proving that in a vacuum tube gases may be luminous at very low temperatures, but we are doubtful whether such a conclusion is very helpful towards the elucidation of our problem. Radiation is a molecular process, and we can speak of the radiation of a molecule but not of its temperature. When we are trying to bring radiation into connexion with temperature, we must therefore take a sufficiently large group of molecules and compare their average energies with the average radiation. The question arises whether in a vacuum discharge, in which only a comparatively small proportion of the molecules are affected, we are to take the average radiation of the affected portion or include the whole lot of molecules, which at any moment are not concerned in the discharge at all. The two processes would lead to entirely different results. The problem, which, in the opinion of the present writer, is the one of interest and has more or less definitely been in the minds of those who have discussed the subject, is whether the type of wave sent out by a molecule only depends on the internal energy of that molecule, or on other considerations such as the mode of excitement. The average energy of a medium containing a mixture of dissimilar elements possesses in this respect only a very secondary interest.

We must now inquire a little more closely into the mechanical conception of radiation. According to present ideas, the wave originates in a disturbance of electrons within the molecules. The electrons responsible for the radiation are probably few and not directly involved in the structure of the atom, which according to the view at present in favour, is itself made up of electrons. As there is undoubtedly a connexion between thermal motion and radiation, the energy of these electrons within the atom must be supposed to increase with temperature. But we know also that in the complete radiation of a white body the radiative energy increases with the fourth power of the absolute temperature. Hence a part of what must be included in thermal energy is not simply proportional to temperature as is commonly assumed. The energy of radiation resides in the medium and not in the molecule. Even at the highest temperatures at our command it is small compared with the energy of translatory motion, but as the temperature increases, it must ultimately gain the upper hand, and if there is anywhere such a temperature as that of several million degrees, the greater part of the total energy of a body will be outside the atom and molecular motion ultimately becomes negligible compared with it. But these speculations, interesting and important as they are, lead us away from our main subject.

[1] *Phil. Mag.* (1881), 12, p. 261.

Considering the great variety of spectra, which one and the same body may possess, the idea lies near that free electrons may temporarily attach themselves to a molecule or detach themselves from it, thereby altering the constitution of the vibrating system. This is most likely to occur in a discharge through a vacuum tube and it is just there that the greatest variety of spectra is observed.

It has been denied by some that pure thermal motion can ever give rise to line spectra, but that either chemical action or impact of electrons is necessary to excite the regular oscillations which give rise to line spectra. There is no doubt that the impact of electrons is likely to be effective in this respect, but it must be remembered that all bodies raised to a sufficient temperature are found to eject electrons, so that the presence of the free electrons is itself a consequence of temperature. The view that visible radiation must be excited by the impact of such an electron is therefore quite consistent with the view that there is no essential difference between the excitement due to chemical or electrical action and that resulting from a sufficient increase of temperature.

Chemical action has frequently been suggested as being a necessary factor in the luminosity of flame, not only in the sense that it causes a sufficient rise of temperature but as furnishing some special and peculiar though undefined stimulus. An important experiment by C. Günther[2] seems however to show that the radiation of metallic salts in a flame has an intensity equal to that belonging to it in virtue of its temperature.

If a short length of platinum wire be inserted vertically into a lighted Bunsen burner the luminous line may be used as a slit and viewed directly through a prism. When now a small bead of a salt of sodium or lithium is placed in the flame the spectrum of the white hot platinum is traversed by the dark absorption of the D lines. This is consistent with Kirchhoff's law and shows that the sodium in a flame possesses the same relative radiation and absorption as sodium vapour heated thermally to the temperature of the flames. According to independent experiments by Paschen the radiation of the D line sent out by the sodium flame of sufficient density is nearly equal to that of a black body at the same temperature.[3] Other more recent experiments confirm the idea that the radiation of flames is mainly determined by their temperature.

The definition of temperature given above, though difficult in the case of a flame and perhaps still admissible in the case of an electric arc, becomes precarious when applied to the disruptive phenomena of a spark discharge. The only sense in which we might be justified in using the word temperature here is by taking account of the energy set free in each discharge and distributing it between the amount of matter to which the energy is supplied. With a guess at the specific heat we might then calculate the maximum temperature to which the substance might be raised, if there were no loss by radiation or otherwise. But the molecules affected by a spark discharge are not in any sense in equilibrium as regards their partition of energy and the word "temperature" cannot therefore be applied to them in the ordinary sense. We might probably with advantage find some definition of what may be called "radiation temperature" based on the relation between radiation and absorption in Kirchhoff's sense, but further information based on experimental investigation is required.

7. *Limits of Homogeneity and Structure of Lines.*—As a first approximation we may say that gases send out homogeneous

[2] *Wied. Ann.* (1877), 2, p. 477.
[3] Ibid. (1894), 51, p. 40.

radiations. A homogeneous oscillation is one which for all time is described by a circular function such as $\sin(nt+a)$, t being the time and n and a constants. The qualification that the circular function must apply to all time is important, and unless it is recognized as a necessary condition of homogeneity, confusion in the more intricate problems or radiation becomes inevitable. Thus if a molecule were set into vibration at a specified time and oscillated according to the above equation during a finite period, it would not send out homogeneous vibrations. In interpreting the phenomena observed in a spectroscope, it is necessary to remember that the instrument, as pointed out by Lord Rayleigh, is itself a producer of homogeneity within the limits defined by its resolving power. A spectroscope may be compared to a mechanical harmonic analyser which when fed with an irregular function of one variable represented by a curve supplies us with the sine curves into which the original function may be resolved. This analogy is useful because the application of Fourier's analysis to the optical theory of spectroscopes has been doubted, and it may be urged in answer to the objections raised that the instrument acts in all respects like a mechanical analyser,[1] the applicability of which has never been called into question.

A limit to homogeneity of radiation is ultimately set by the so-called Doppler effect, which is the change of wave-length due to the translatory motion of the vibrating molecule from or towards the observer. If N be the frequency of a homogeneous vibration sent out by a molecule at rest, the apparent frequency will be $N(1 \pm v/V)$, where V is the velocity of light and v is the velocity of the line of sight, taken as positive if the distance from the observer increases. If all molecules moved with the velocity of mean square, the line would be drawn out into a band having on the frequency scale a width $2Nv/V$, where v is now the velocity of mean square. According to Maxwell's law, however, the number of molecules having a velocity in the line of sight lying between v and $v+dv$ is proportional to $e^{-\beta v^2}dv$, where β is equal to $3/2u^2$; for $v=u$, we have therefore the ratio in the number of molecules having velocity u to those having no velocity in the line of sight $e^{-\beta u^2}=e^{-\frac{3}{2}}=\cdot 22$. We may therefcre still take $2Nu/V$ to be the width of the band if we define its edge to be the frequency at which its intensity has fallen to 22% of the central intensity. In the case of hydrogen rendered luminous in a vacuum tube we may put approximately u equal to 2000 metres per second, if the translatory motion of the luminous molecules is about the same as that at the ordinary temperature. In that case $\lambda u/V$ or the half width of the band measured in wave lengths would be $\frac{2}{3}\cdot 10^{-5}\lambda$, or, for the red line, the half width would be 0·044 Å. Michelson, who has compared the theoretical widening with that found experimentally by means of his interferometer, had to use a somewhat more complicated expression for the comparison, as his visibility curve does not directly give intensities for particular frequencies but an integral depending on a range of frequency.[2] He finds a remarkable agreement between the theoretical and experimental values, which it would be important to confirm with the more suitable instruments which are now at our disposal, as we might in this way get an estimate of the energy of translatory motion of the luminous molecules. If the motion were that of a body at white heat, or say a temperature of 1000°, the velocity of mean square would be 3900 metres per second and the apparent width of the band would be doubled. Michelson's experiments therefore argue in favour of the view that the luminescence in a vacuum tube is similar to that produced by phosphorescence where the translatory energy does not correspond to the oscillatory energy—but further experiments are desirable. The experimental verification of the change of wave-length due to a source moving in the line of sight has been realized in the laboratory by A. Bélopolsky and Prince Galitzin, who substituted for the source an image formed of a stationary object in a rapidly moving mirror.

[1] *Phil. Mag.* (1894), 37, p. 509.
[2] Cf. Rayleigh, *Phil. Mag.* (1899), 27, p. 298; Michelson, *Phil. Mag.* (1892), 34, p. 280.

The homogeneity of vibration may also be diminished by molecular impacts, but the number of shocks in a given time depends on pressure and we may therefore expect to diminish the width of a line by diminishing the pressure. It is not, however, obvious that the sudden change of direction in the translatory motion, which is commonly called a molecular shock, necessarily also affects the phase of vibration. Experiments which will be discussed in § 10 seem to show that there is a difference in this respect between the impacts of similar and those of dissimilar molecules. When the lines are obtained under circumstances which tend towards sharpness and homogeneity they are often found to possess complicated structures, single lines breaking up into two or more components of varying intensities. One of the most interesting examples is that furnished by the green mercury line, which when examined by a powerful échelon spectroscope splits up into a number of constituents which have been examined by several investigators. Six companions to the main lines are found with comparative ease and certainty and these have been carefully measured by Prince Galitzin,[3] H. Stansfield[4] and L. Janicki.[5] According to Stansfield there are three companion lines on either side of a central line, which consists of two lines of unequal brightness.

8. *Distribution of Frequencies in Line Spectra.*—It is natural to consider the frequencies of vibrations of radiating molecules as analogous to the different notes sent out by an acoustical vibrator. The efforts which were consequently made in the early days of spectroscopy to discover some numerical relationship between the different wave lengths of the lines belonging to the same spectrum rather disregard the fact that even in acoustics the relationship of integer numbers holds only in special and very simple cases. Some corroboration of the simple law was apparently found by Johnstone Stoney, who first noted that the frequencies of three out of the four visible hydrogen lines are in the ratios 20 : 27 : 32. In other spectra such "harmonic" ratios were also discovered, but their search was abandoned when it was found that their number did not exceed that calculated by the laws of probability on the supposition of a chance distribution.[6] The next great step was made by J. J. Balmer, who showed that the four hydrogen lines in the visible part of the spectrum may be represented by the equation

$$n = A(1 - 4/s^2),$$

where n is the reciprocal of the wave-length and therefore proportional to the wave frequency, and s successively takes the values 3, 4, 5, 6. Balmer's formula received a striking confirmation when it was found to include the ultra-violet lines which were discovered by Sir William Huggins[7] in the photographic spectra of stars. The most complete hydrogen spectrum is that measured by Evershed[8] in the flash spectrum observed during a total solar eclipse, and contains thirty-one lines, all of which agree with considerable accuracy with the formula, if the frequency number n is calculated correctly by reducing the wave-length to vacuo.[9]

It is a characteristic of Balmer's formula that the frequency approaches a definite limit as s is increased, and it was soon discovered that in several other spectra besides hydrogen, series of lines could be found, which gradually come nearer and nearer to each other as they become fainter, and approach a definite limit. Such series ought all to be capable of being represented by a formula resembling that of Balmer, but so far the exact form of the series has not been established with certainty. The more important of the different forms suggested are as follow:

(1) $n = A + \frac{B}{s^2} + \frac{C}{s^4}$ (H. Kayser and C. Runge).

(2) $n = A - \frac{N}{s(+\mu)^2}$ (J. R. Rydberg).

[8] Ibid (1891), 197, p. 381.
[9] The table so corrected will be found in C. Baly's *Spectroscopy*, p. 472.

(3) $n = \mathrm{A} - \frac{\mathrm{N}}{(s+\mu)^2 + a}$ (E. C. Pickering, generalized by T. N. Thiele).

(4) $n = \mathrm{A} - \frac{\mathrm{N}}{(r+a+b/r^2)^2}$ (Ritz).

(5) $n = \mathrm{A} - \frac{\mathrm{N}}{(s+\mu+a/s)^2}$ (Hicks).

In all cases s represents the succession of integer numbers. In the last case we must put for r either s or $s+\frac{1}{2}$ according to the nature of the series, as will be explained further on. The first of the forms which contains three disposable constants did good service in the hands of their authors, but breaks down in important cases when odd powers of s have to be introduced in addition to the even powers. The second form contains two or three constants according as N is taken to have the same value for all elements or not. Rydberg favours the former view, but he does not attempt to obtain any very close approximation between the observed and calculated values of the frequencies. Equation (3), which E. C. Pickering[1] used in a special case, presently to be referred to, was put into a more general form by Thiele,[2] who, however, assumes N to have the same value for all spectra, and not obtaining sufficient agreement, rejects the formula. J. Halm[3] subsequently showed that if N may differ in different cases, the equation is a considerable improvement on Rydberg's. It then possesses four adjustable constants, and more can therefore be expected from it. All these forms are put into the shade by that which was introduced by Ritz, led thereto apparently by theoretical considerations. As he takes N to be strictly the same for all elements the equation has only three disposable constants A, a and b. It is found to be very markedly superior to the other equations. Its chief advantage appears, however, when the relationship between different series of the same element is taken into account. We therefore turn our attention to this relationship.

In the case of those elements in which we can represent the spectrum most completely by a number of series, it is generally found that they occur in groups of three which are closely related to each other. They were called by H. Kayser and F. Paschen "Haupt serie," "1st Nebenserie," "2nd Nebenserie," which is commonly translated "Principal series," "First subordinate series," "Second subordinate series." These names become inconvenient when, as is generally the case, each of the series splits into groups of two or three, and we have to speak of the second or third number of the first or second subordinate series. Moreover, a false impression is conveyed by the nomenclature, as the second subordinate series is much more closely related to the principal series than the first subordinate series. The present writer, therefore, in his *Theory of Optics*, adopted different names, and called the series respectively the "Trunk," the "Main Branch" and the "Side Branch," the main branch being identical with the second subordinate series; the limit of frequency for high values of s is called the "root" of the series, and it is found in all cases that the two branches have a common root at some point in the trunk. According to an important law discovered by Rydberg and shortly afterwards independently by the writer, the frequency of the common root of the two branches is obtained by subtracting the frequency of the root of the trunk from that of its least refrangible and strongest member. In the spectra of the alkali metals each line of the trunk is a doublet, and we may speak of a twin trunk springing out of the same root. In the same spectra the lines belonging to the two branches are also doublets. According to the above law the least refrangible member of the trunk being double, there must be two roots for the branches, and this is found to be the case. In fact the lines of each branch are also doublets, with common difference of frequency. There are, therefore, two main branches and two side branches, but these are not twins springing out of the same root, but parallel branches springing out of different though closely adjacent roots. It will also be noticed that the least refrangible of the doublets of the branches must according to the above law correspond to the most refrangible of the doublets of the trunk, and if the components of the doublets have different intensities the stronger components must lie on different sides in the trunk and branch series. This is confirmed by observation. Rydberg discovered a second relationship, which, however, involving the assumed equation connecting the different lines, cannot be tested directly as long as these equations are only approximate. On the other hand the law, once shown to hold approximately, may be used to test the sufficiency of a particular form of equation. These forms all agree in making the frequency negative when s falls below a certain value s_p. Rydberg's second law states that if the main branch series is taken, the numerical value of n_{p-1} corresponding to s_{p-1} is equal to the frequency of the least refrangible member of the trunk series.

[1] *Astrophys. Journ.* (1896), 4, p. 369.
[2] Ibid. (1897), 6, p. 65.
[3] *Trans. Ast. Soc. Edinburgh* (1905), 41, p. 551.

The two laws are best understood by putting the equations in the form given them by Rydberg.

For the trunk series write

$$\frac{n_s}{\mathrm{N}} = \frac{1}{(1+\sigma)^2} - \frac{1}{(s+\mu^2)},$$

and for the main branch series

$$\frac{n^1_s}{\mathrm{N}} = \frac{1}{(1+\mu)^2} - \frac{1}{(s+\sigma)^2}.$$

Here μ, σ and N are constants, while s as before is an integer number.

The difference between the frequencies of the roots ($s=\infty$) is given by

$$n_\infty - n^1{}_\infty = \mathrm{N}\left[\frac{1}{(1+\sigma)^2} - \frac{1}{(1+\mu)^2}\right] = n_1.$$

This is the first law.

If further in the two equations we put $s=1$, we obtain:

$$n_1 = -n_1{}^1.$$

This is the second law.

As has already been mentioned, the law is only verified very roughly, if Rydberg's form of equation is taken as correctly representing the series. The fact that the addition of the term introduced by Ritz not only gives a more satisfactory representation of each series, but verifies the above relationship with a much closer degree of approximation, proves that Ritz's equation forms a marked step in the right direction. According to him, the following equations represent the connexion between the lines of the three related series.

Trunk series: $\pm\frac{n_s}{\mathrm{N}} = \frac{1}{[s+a_1+b/s^2]^2} - \frac{1}{[1{\cdot}5+a^1+b'/(1{\cdot}5)^2]^2}.$

Main Branch Series: $\pm\frac{n_r{}^1}{\mathrm{N}} = \frac{1}{[2+a_1+b/2^2]^2} - \frac{1}{[r+a^1+b^1/r^2]^2}.$

Side Branch Series: $\pm\frac{n_r{}^{11}}{\mathrm{N}} = \frac{1}{[2+a_1+b/2^2]^2} - \frac{1}{[s+c+d/s^2]^2}.$

Here s stands for an integer number beginning with 2 for the trunk and 3 for the main branch, and r represents the succession of numbers 1·5, 2·5, 3·5, &c. As Ritz points out, the first two equations appear only to be particular cases of the form

$$\frac{n}{\mathrm{N}} = \frac{1}{(s+\alpha)^2} - \frac{1}{(r+\beta)^2}$$

in which s and r have the form given above. In the trunk series s has the particular value 1·5, and in the main branch series s has the particular value 2, but we should expect a weaker set of lines to exist corresponding to the trunk series with $r=2{\cdot}5$ or corresponding to the main branch series with $s=3$, and in fact a whole succession of such series. Taking the Trunk and Main Branch Series, we find they depend altogether on the four constants: a_1, b, a^1, b^1, while N is a universal constant identical with that deduced from the hydrogen series. As an example of the accuracy obtained we give in the following Table the figures for potassium. The lines of the trunk series are double but for the sake of shortness the least refrangible component is here omitted.

Spectrum of Potassium.

W. M. Hicks[1] has modified Rydberg's equation in a way similar to that of Ritz as shown by (5) above. This form has the advantage that the constants of the equation when applied to the spectra of the alkali metals show marked regularities. The most extensive series which has yet been observed is that of the trunk series of sodium when it is observed as an absorption spectrum; R. W. Wood has in that case measured as many as 50 lines belonging to this series.

The different series have certain characteristics which they seem to maintain wherever they have been obtained. Thus the trunk series consists of lines which are easily reversed while those of the side branch are nebulous. The lines of the trunk seem to appear at lower temperatures, which may account for the fact that it can be observed as absorption lines. If we compare together the spectra of the alkali metals, we find that the doublets of the branch series separate more and more as the wave-length increases. Roughly speaking the difference in frequency is proportional to the square of the atomic weight. Taking sodium and lithium we find in this way that the lithium lines ought to be double and separated by ·7 Å. They have not, however, so far as we know, been resolved. The roots of the three series have frequencies which diminish as the atomic weight increases, but not according to any simple law.

In the case of other metallic groups similar series have also been found, but while in the case of the alkali group nearly the whole spectrum is represented by the combined set of three series, such is not the case with other metals. The spectra of magnesium, calcium, zinc, cadmium and mercury, give the two branch series, and each series is repeated three times with constant difference of frequency. In these elements the doublets of the alkali series are therefore replaced by triplets. Strontium also gives triplets, but only the side branch series has been observed. In the spectrum of barium no series has yet been recognized. The spectrum of helium has been very carefully studied by Runge and Paschen. All its lines arrange themselves in two families of series, in other words, the spectrum looks like that of the superposition of two spectra similar to those presented by the alkali metals. Each family consists of the trunk, main branch and side branch. The conclusion which was originally drawn from this fact that helium is a mixture of two gases has not been confirmed, as one of the spectra of oxygen is similarly constituted.

We must refer to Kayser and Runge's *Handbuch* for further details, as well as for information on other spectra such as those of silver, thallium, indium and manganese, in which series lines have been found.

Before leaving the subject, we return for a moment to the spectrum of hydrogen. In 1896, Professor E. C. Pickering discovered in the structure of the star ξ Puppis a series of lines which showed a remarkable similarity to that of hydrogen having the same root. Kayser on examining the spectrum recognized the fact that the two series were related to each other like the two branch series, and this was subsequently confirmed. If we compare Balmer's formula with the general equation of Ritz, we find that the two can be made to agree if the ordinary hydrogen spectrum is that of the side branch series and the constants a^1, b, c and d are all put equal to zero. In that case the main branch is found to represent the new series if a^1 and b^1 are also put equal to zero, so that

$$+\frac{n^1{}_r}{N}=\frac{1}{4}-\frac{1}{r^2},$$

where r takes successively the values 1·5, 2·5, 3·5. A knowledge of the constants now determines the trunk series, which should be

$$\frac{n}{N}=\left(\frac{1}{(1.5)^2}-\frac{1}{s^2}\right).$$

The least refrangible of the lines of this series should have a wave-length 4687·88, and a strong line of this wave-length has indeed been found in the spectra of stars which are made up of bright lines, as also in the spectra of some nebulae. It seems remarkable, however, that we should not have succeeded yet in reproducing in the laboratory the trunk and main branch of the hydrogen spectrum, if the spectra in question really belong to hydrogen.

Considering the complexity of the subject it is not surprising that the efforts to connect theoretically the possible periods of the atom considered as a vibrating system have met with no considerable success. Two methods of investigation are available. The one endeavours to determine the conditions, which are consistent with our knowledge of atomic constitution derived from other sources, and lead to systems of vibration similar to those of the actual atom. We might then hope to particularize or modify these conditions so as to put them into more complete agreement. An attempt in that direction has been made with partial success by J. H. Jeans,[2] who showed that a shell-like constitution of the atom, the shells being electrically charged, would lead to systems of periods not unlike those of a series of lines such as is given by observation. The other method starts from the observed values of the periods, and establishes a differential equation from which these periods may be derived. This is done in the hope that some theoretical foundation may then be found for the equation. The pioneer in this direction is E. Riecke,[3] who deduced a differential equation of the 10th order. Ritz in the paper already mentioned follows in the footsteps of Riecke and elaborates the argument. On the whole it seems probable that the system of moving electrons, which according to a modern theory constitute the atom, is not directly concerned in thermal radiation which would rather be due to a few more loosely connected electrons hanging on to the atom. The difficulty that a number of spectroscopic lines seem to involve at least an equal number of electrons may be got over by imagining that the atom may present several positions of equilibrium to the electron, which it may occupy in turn. A collision may be able to throw the electrons from one of these positions to another. According to this view the different lines are given out by different molecules, and we should have to take averages over a number of molecules to obtain the complete spectrum just as we now take averages of energy to obtain the temperature.[4] If it should be confirmed that the period called N in the above investigation is the same for all elements, it must be intimately connected with the structure of the electron. At present the quantity of electricity it carries, and also its mass, may be determined, and we can therefore derive units of length and of mass from our electrical measurements. The quantity N may serve to fix the third fundamental unit. One further point deserves notice. Lord Rayleigh,[5] who has also investigated vibrating systems giving series of lines approaching a definite limit of "root," remarks that by dynamical reasoning we are always led to equations giving the square of the period and not the period, while in the equation representing spectral series the simplest results are obtained for the first power of the period. Now it follows from Rydberg's second law put on a more accurate basis by Ritz that in one case at any rate a *negative* period has reality and must be interpreted just as if it were positive. This looks indeed as if the *square* of the period were the determining quantity.

9. *Distribution of Frequencies in Band Spectra.*—In many cases the spectra of molecules consist of lines so closely ruled together in groups as to give the appearance of continuous bands unless high resolving powers are employed. Such spectra seem to be characteristic of complex molecular structure, as they appear when compounds are raised to incandescence without decomposition, or when we examine the absorption spectra of vapours such as iodine and bromine and other cases where we know that the molecule consists of more than one atom. The bands often appear in groups, and such spectra containing groups of bands when viewed through small spectroscopes sometimes give the appearance of the flutings of columns. Hence the name "fluted spectra," which is sometimes applied. Each band, as has been stated, is made up of lines indicating highly homogeneous vibrations. A systematic study of the distribution of frequencies in these bands was first made by H. Deslandres,[6] who found that the successive differences in the frequencies formed an arithmetical progression.

If s represents the series of integer numbers the distribution of frequency may be represented by

$$n=C+Bs^2,$$

where C and B are constants. The brightest line, for which $s=0$, is called the "head" of the band; and as s increases the lines diminish in intensity. The band fades towards the red or violet according as A is positive or negative, and the appearance is sometimes complicated by the fact that several sets of lines start from identical or closely adjoining heads. The equation which expressed "Deslandres' law" was only given by its author as an approximate one. The careful measurements of Kayser and Runge of the carbon bands show that the successive differences in the frequencies do

[1] *Proc. Roy. Soc.* (1909), 83, p. 226 (abstract).

[6] *Comptes rendus* (1885), 100, p. 1256.

not quite keep up with the mathematical expression but tend to become more equal. The distances between the two first lines is A, and is small compared with the frequency itself, which is B.

If this is the case it is obvious that an equation of the form

$$n = \mathrm{A} - \frac{\mathrm{N}}{s^2 + a}$$

does, for small values of s, becomes identical with Deslandres' equation, a representing a constant which is large compared with unity. If we wish to be more general, while still adhering to Deslandres' law as a correct representation of the frequencies when s is small, we may write

$$n = \mathrm{A} - \frac{\mathrm{N}}{(s+\mu)^2 + a},$$

where μ is an additional constant.

We have now reduced the law for the bands to a form which we have found applicable to a series of lines, but with this important difference that while a in the case of line spectra is a small corrective term, it now forms the constant on which an essential factor in the appearance of the band depends. Halm,[1] to whom we owe a careful comparison of the above equation with the observed frequencies in a great number of spectra, attached perhaps too much weight to the fact that it is capable of representing both line and band spectra. It is no doubt important to recognize that the two types of spectra seem to represent two extreme cases of one formula, the significant difference being that in the line spectrum the distance between lines diminishes as we recede from the head, while in the case of the band it increases, at any rate to begin with. But, on the other hand, no one pretends to have found the rigorous expression for the law, and the appropriate approximation may take quite different forms when constants which are large in one case are small in the other. It would not therefore be correct to push this agreement against Ritz's expression which is not applicable to bands.

A discussion of band spectra on a very broad basis was given by Thiele,[2] who recommends a formula

$$n = \frac{q_0 + q_1(s+c) + \ldots\ldots\ldots + q_r(s+c)^r}{p_0 + p_1(s+c) + \ldots\ldots\ldots + p_r(s+c)^r},$$

where s as before represents the integer numbers and the other quantities involved are constants. If $r=1$, we obtain Pickering's equation, which is the one advocated by Halm. Equations of this form have received a striking observational verification in so far as they predict a tail or root towards which the lines ultimately tend when s is increased indefinitely. This fact bridges over the distinction between the band and line spectra. The distance between the lines measured on the frequency scale does not, according to the equation, increase indefinitely from the head downwards, but has a maximum which, in Pickering's form as written above, is reached when $(s+\mu)^2 = \frac{1}{3}a$. This gives a real value for s only when a is positive. If a is negative the frequency passes through infinity and the maximum distance between the lines occurs there. If we only assign positive values to n and a, the band fades away from the head, the lines at first increasing in distance. It appears from the observations of A. S. King,[3] that in the case of the so-called spectrum of cyanogen these tails can be observed. If a negative value of the frequency is admitted, more complicated effects may be predicted. A band might in that case fade away towards zero frequencies, and as s increases, return again from infinity with diminishing distances, the head and the tail pointing in the same direction; or with a different value of constants a band might fade away towards infinite frequencies, then return through the whole range of the spectrum to zero frequencies, and once more return with its tail near its head. The same band may therefore cross its own head on the return journey. If we adopt Thiele's view that each band is accompanied by a second branch for which s has negative values the complication is still further increased, but there does not seem to be sufficient reason to adopt this view.

10. *Effects of Varying Physical Conditions*.—The same spectrum may show differences according to the physical conditions under which the body emitting the spectrum is placed. The main effects we have to discuss are (1) a symmetrical widening, (2) a shift of wave-length, which when it accompanies expansion in both directions may appear as an unsymmetrical widening, (3) a change in the relative intensities of the lines.

As typical examples illustrating the facts to be explained, the following may be mentioned. (*a*) When a sodium salt is placed in a Bunsen burner in sufficient quantity, the yellow lines are widened. When the amount of luminous matter is small the lines remain narrow. (*b*) If a spark be sent through a Plücker tube containing hydrogen the lines are widened when the pressure is increased. (*c*) Under moderate pressures the lines of hydrogen may be widened by powerful sparks taken from a condenser. (*d*) If a spark be taken from an electric condenser through air, both the lines of oxygen and nitrogen are wide compared with what they would be at low pressures. But a mixture of nitrogen and oxygen containing only little nitrogen will show the nitrogen lines narrow and similarly narrow oxygen lines may be obtained if the quantity of oxygen is reduced. (*e*) If a spark be taken from a solution of a salt, *e.g.* lithium, the relative intensities of the lines are different according as the solution is concentrated or dilute. (*f*) The relative intensity of lines in the spark taken from metallic poles may be altered by the insertion of greater or smaller capacities, similarly the relative intensities are different in arc and spark spectra. (*g*) Increased pressure nearly always diminishes the frequency of vibration, but this effect is generally of a smaller order of magnitude than the widening which takes place in the other cases. In investigating the effects of mixture on the widening of lines in absorption spectrum, R. W. Wood discovered some interesting effects. The cadmium line having a wave-length of 2288 Å broadens by pressure equally in both directions, but if mercury be added the broadening is more marked on the less refrangible side.

The discussion as to the causes of this widening has turned a good deal on the question whether it is primarily due to changes of density, pressure or temperature, but some confusion has been caused by the want of proper definition of terms. For the cause of this the writer of the present article is jointly with others at any rate partly responsible, and clearness of ideas can only be re-established by investigating the mechanical causes of the effect rather than by applying terms which refer to a different order of physical conceptions.

The facts, as quoted, point to the closeness of the packing of molecules as the factor which always accompanies and perhaps causes the widening of lines. But is this alone sufficient to justify us in assigning the widening to increased density? Increased density at the same temperature means in the first place a reduction of the average distance between the molecules, but it means also a reduction in the mean free path and an increase in the number of impacts. The question is: which of these three factors is significant in the explanation of the widening? If it is the average distance irrespective of length of path and of number of impacts we should be justified in ascribing the effect to density, but if it is the number of impacts it would be more reasonable to ascribe it to pressure. The question could not be settled by experiments made at the same temperature, and if the temperature is altered the question is complicated by the distinction which would probably have to be drawn between the number of collisions and their intensity. Experimentally we should be confined to a strict investigation of absorption spectra, because in the electric discharge temperature has no definite meaning, and variations of pressure and density are not easily measured.

Assuming for a moment the change to be one of density and leaving out of account the pressure shift, the cases (*e*) and (*f*) point to the fact that it is the closeness of packing of *similar* molecules which is effective, *e.g.* the number of oxygen molecules per cubic centimetre determines the width of the oxygen lines, though nitrogen molecules may be mixed with them without materially affecting the appearance. Experiment (*c*) is, however, generally taken to mean that this closeness of packing cannot be the sole determining cause, for it is argued that if a closed vacuum tube can show both wide and narrow lines according to the mode of discharge, density alone cannot account for the change. But this argument is not conclusive, for though the total number of hydrogen molecules is fixed when the gas is enclosed, yet the number of luminous molecules may vary with the condition. Those that are not luminous may, if they do not contain the same vibrating system, behave like inert molecules. When an electric current from a battery is sent through a tube containing hydrogen, increase of current simply means increase in the number of ions which take part

[1] *Trans. Roy. Soc. Edin.* (1905), 41, p. 551.
[2] *Astrophys. Journ.* (1897), 6, p. 65; (1898), 8, p. 1.
[3] Ibid. (1901), 14. p. 323.

in the discharge, except within the region of the kathode glow. Each molecule need not radiate with increased energy, but the more brilliant emission of light may be due to the greater number of particles forming similar vibrating systems.

When we compare together electric discharges the intensity of which is altered by varying the capacity, we are unable to form an opinion as to whether the effects observed are due to changes in the density of the luminous material or changes of temperature, but the experiments of Sir William and Lady Huggins[1] with the spectrum of calcium are significant in suggesting that it is really the density which is also the determining factor in cases where different concentrations and different spark discharges produce a change in the relative intensities of different lines.

The widening of lines does not lend itself easily to accurate measurements; more precise numerical data are obtainable by the study of the displacements consequent on increased density which were discovered and studied by W. J. Humphreys and J. F. Mohler. In the original experiments[2] the pressures could only be increased to 15 atmospheres, but in a more recent work Humphreys,[3] and independently Duffield, were able to use pressures up to 100 atmospheres. The change of frequency (dn) for a series of lines which behave similarly is approximately proportional to the frequency (n) so that we can take the fraction dn/n as a measure of the shift. It is found that the lines of the same element do not all show the same shift, thus the calcium line at 4223 is displaced by 0·4 Å by 100 atmospheres pressure, while the H and K lines are only displaced through about half that amount. Duffield finds that the iron lines divide themselves into three groups with pressure shifts which are approximately in the ratio 1 : 2 : 4. Curiously enough this is also approximately the ratio of the displacements found by Humphreys in the trunk series, the side branch and main branch in the order named, in cases where these displacements have been measured. It was believed that band spectra did not show any pressure shift, until A. Dufour[4] discovered that the lines into which the band spectra of the fluorides of the alkaline earths may be resolved widen towards the red under increased pressure.

Let us now consider the causes which may affect the homogeneity of radiation. We have first the Doppler effect, which, according to Michelson's experiment, is the chief cause of the limit at very low pressures, but it is too small to account for the widening which is now under discussion. We have further to consider the possibility of sudden changes of phrase during an encounter between two molecules, and we can easily form an estimate of the amount of apparent widening due to this cause. It is found to be appreciable but smaller than the observed effects.

Shortly after the discovery of pressure shifts A. Schuster[5] suggested that the proximity of molecules vibrating in the same period might be the cause of the diminished frequency, and suggested that according to this view the shifts would be similar if the increase of density were produced by the presence of molecules of a different kind from those whose lines are being examined. Though there is no absolutely conclusive evidence, no experiments hitherto have given any indication that the nature of the gas producing the pressure has any effect on the amount of shift. G. F. Fitzgerald[6] suggested as an alternative explanation the change of inductive capacity of the medium due to increased density. J. Larmor[7] developed the same idea, and arrived by a very simple method at an approximation estimate of the shift to be expected.

If the medium which contains the vibration is divided into a sphere equal to k times the molecular vibration outside of which the effects of these molecules may be averaged up, so that its inductive capacity may be considered uniform and equal to K, the frequency of the vibration is increased in the ratio of the square root of $1 - k^{-2n+3}(1 - K^{-1})$ to 1. Here n represents an integer which is 3 if the vibration is a simple doublet, but may have a higher integer value. If K has a value nearly equal to unity, the pressure shift is $\frac{1}{2}k^{-2n+3}(K^{-1} - 1)$ and it is significant that for different values of n, the shifts should be in geometric ratio, because as stated above, the ratio occurring in the amounts observed with different lines of the same element are as 1 : 2 : 4. The question is complicated by the fact that in the cases which have been observed, the greater portion of the metallic vapour vibrates in an atmosphere of similar molecules, and the static energy of the field is determined by the value of K applicable to the particular frequency. It would therefore seem to be more appropriate to replace $1 - K^{-1}$ by $(\mu^2 - 1)/\mu^2$, where μ is the refractive index; but this expression involves the wave propagation for periods coinciding with free periods of the molecules. Close to and on either side of the absorptive band μ^2 has large positive and negative values, and if the above expression remains correct the change of frequency would, close to the centre of absorption, be $\frac{1}{2}k^{-2n+3}$, which for $n=3$ and $k=10$ is 1/2000, or 500 times greater than the observed shifts, but this represents now the *maximum* displacement and not the displacement of the most intense portion of the radiation. There is a region within the band where $\mu = 0$, and this would give an infinite shift in the opposite direction. We therefore should expect a band in place of the line, which is the case, but our calculation is not able to give the displacement of the most intense portion, which is what we require for comparison with experiment.

The effects of resonance have been studied theoretically by Prince Galitzin[8] and later by V. W. Ekman.[9] The latter obtains results indicating no displacement but a widening. He concludes an interesting and important investigation by giving reasons for believing that the centre of a widened line radiates with smaller energy than the adjacent parts. Hence the apparent reversals so frequently observed in the centre of a widened line may not be reversals at all but due to a reduction in luminosity. Ekman quotes in support an observation due to C. A. Young, according to which the dark line observed in the centre of each component of the sodium doublet in a Bunsen burner is *transparent* to a radiation placed behind. It should not be difficult to decide whether the reversals are real or fictitious.

Leaving the consideration of radical changes of a vibrating system out of account for the present, the minor differences which have been observed in the appearances of spectra under different sparking conditions are probably to a large extent due to differences in the quantities of material examined, though temperature must alter the violence of the impact and there is a possible effect due to a difference in the impact according as the vibrating system collides with an electron or with a body of atomic dimensions.

A. Schuster and G. A. Hemsalech have observed that the insertion of a self-induction in a condenser discharge almost entirely obliterates the air lines, and the same effect is produced by diminishing the spark gap sufficiently. The explanation of these facts presents no difficulty, inasmuch as during the sudden discharge which takes place in the absence of a self-induction, the metallic molecules have not sufficient time to diffuse through the spark gap; hence the discharge is carried by the gas in which it takes place. When, however, the time of discharge is lengthened, the conditions of the arc are more nearly approached. When the spark gap is small, the sudden evaporation of the metal has a better chance of filling the interval between the poles, even without the introduction of a self-induction.

Enhanced lines are lines which appear chiefly near the pole when strong spark discharges are used. Their presence indicates the characteristic difference between the spark and the arc. The name is due to Sir Norman Lockyer, who has studied these lines and drawn the attention of astronomers to their importance in interpreting stellar spectra. These lines in the case of the spark cannot be due entirely to the increased mass of vapour near the poles, but indicate a real change of spectrum probably connected with a higher temperature.

11. *Molecular Velocities.*—A. Schuster and G. A. Hemsalech[1] have measured the velocity with which the luminous molecules are projected from metallic poles when a strong spark is passed through the air interval which separates the poles. The method adopted consisted in photographing the spectrum on a film which was kept in rapid motion by being attached to the front of a rotating disk. The velocities ranged from about 400 to 1900 metres, the metals of small atomic weight giving as a rule the higher velocities. In the case of some metals, notably bismuth, the velocity measured was different for different lines, which seems intelligible only on the supposition that the metal vapour consists of different vibrating systems which can differ with different velocities. C. C. Schenck[2] subsequently conducted similar experiments, using a rotating mirror, and though he put a different interpretation on the effects, the main conclusions of Schuster and Hemsalech were not affected. These have further been confirmed and extended by the experiments of J. T. Royds made with the same rotating disk, but with improved optical appliances. The photographs taken by Royds show the separate oscillations of each spark discharge even when the circuit only contained the unavoidable capacity of the leads. It was found that during the successive electrical oscillations the metallic lines can be observed to stretch farther and farther away from the poles, thus giving a measure of the gradual diffusion of the metal. The subject wants further investigation, especially with a view to deciding the connexion between the molecular rush and the discharge. While some of the phenomena seem to indicate that the projection of metallic vapours into the centre of the spark is a process of molecular diffusion independent of the mechanism of the discharge, the different velocities obtained with bismuth, and the probability that the vibrating systems are not electrically neutral, seem to indicate that the projected metallic particles are electrified and play some part in the discharge.

12. *The Zeeman Effect.*—The change of frequency of oscillation of radiating molecules placed in a magnetic field, which was discovered by P. Zeeman, and the observed polarization of the components, are all beautifully explained by the theory of H. A. Lorentz, and leave no manner of doubt that the radiating centres are negative electrons. The fact that in certain simple cases where a line when looked at equatorially splits into a triplet, the ratio of the charge to the mass is found by Lorentz's theory to be equal to that observed in the carrier of the kathode ray, shows that in these cases the electron moves as an independent body and is not linked in its motion to other electrons. On the other hand, most of the lines show a more complicated structure in the magnetic field, suggesting a system of electrons rather than a single free corpuscle. The question has been fully discussed by C. Runge in the second volume of Kayser's *Handbuch* (see also MAGNETO-OPTICS), and we may therefore content ourselves with the mention of the law discovered by Th. Preston that all the lines of the same series show identical effects when measured on the frequency scale, and the fact recently announced by Runge[3] that even in the more complicated cases mentioned some simple relation between the distances of the components exists. If a is the distance shown by the normal triplets the type of separation observed in the line D_2 shows distances from the central line equal to $a/3$, $3a/3$, $5a/3$, while the type of D_1 gives $2a/3$, $4a/3$. In all observed cases the distances are multiples of some number which itself is a sub-mutiple of a. The component lines of a band spectrum do not as a rule give the Zeeman effect, and this seems to be connected with their freedom from pressure shifts, for when Dufour had shown that the bands of the fluoride of calcium were sensitive to the magnetic field, R. Rossi[4] could show that they were also sensitive to pressure.

13. *Identification of Spectra.*—The interpretation of spectroscopic observation seemed very simple when Kirchhoff and Bunsen first announced their discovery, for according to their view every combination of an element showed the characteristic spectrum of its constituent atoms; it did not matter according to this view whether a salt, *e.g.* sodium chloride, introduced into a flame, was dissociated or not, as in either case the spectrum observed would be that of sodium. It was soon found, however, that compounds possess their own characteristic spectra, and that an element may give under special conditions of luminosity several different spectra. When we now speak of the identification of spectra we like to include, wherever possible, the identification of the particular compound which is luminous and even—though we have only begun to make any progress in that direction—the differentiation between the molecular or electronic states which yield the different spectra of the same element.

One preliminary question must first be disposed of. The fact that the gases with which we are most familiar are not rendered luminous by being heated in a tube to a temperature well above a white heat has often been a stumbling block and raised the not unreasonable doubt whether approximately homogeneous oscillations could ever be obtained by a mere thermal process. The experiment proves only the transparency of the gases experimented upon, and this is confirmed by the fact that bodies like bromine and iodine give on heating an emission spectrum corresponding to the absorption spectrum seen at ordinary temperatures. The subject, however, required further experimental investigation, which was supplied by Paschen. Paschen proved that the emission spectra of water vapour as observed in an oxyhydrogen flame and of carbon dioxide as observed in a hydrocarbon flame may be obtained by heating aqueous vapour and carbon dioxide respectively to a few hundred degrees above the freezing point. The same author proved that a sufficient thickness of layer raised the radiation to that of a black body in agreement with Kirchhoff's law. The spectra experimented on by Paschen were band spectra, but as these split up into fine lines the possibility of homogeneous radiation in pure thermal oscillation may be considered as established. Paschen's observations originated in the desire to decide the question raised by E. Pringsheim, who, by a series of experiments of undoubted merit, tried to establish that the emission of the line spectra of the alkali metals was invariably associated with a reduction of the metallic oxide. Pringsheim seems, however, to have modified his view in so far as he now seems to consider that the spectra in question might be obtained also in other ways, and to attach importance to the process of reduction only in so far as it forms an effective inciter of the particular spectra. In spite of the fact that C. Fredenhagen has recently attempted to revive Pringsheim's original views in a modified form—substituting oxidation for reduction—we may consider it as generally admitted that the origin of spectra lies with vibrating systems which are definite and not dependent on the method of incitement. These systems may only be semi-stable, but they must last a sufficient length of time to give a train of waves having a length corresponding to the observed homogeneity of the line.

In many cases there is a considerable difficulty in deciding whether a particular spectrum belongs to a compound body or to one of the elements composing the compound. Thus one of the most common spectra is that seen at the base of every candle and in every Bunsen burner. Everybody agrees that carbon is necessary for its appearance, but some believe it to be due to a hydrocarbon, others to carbon monoxide, and others to volatilized carbon. There is a vast amount of literature on the subject, but in spite of the difficulty of conceiving a luminous carbon vapour at the temperature of an ordinary carbon flame, the evidence seems to show that no other element is necessary for its production as it is found in the spectrum of pure carbon tetrachloride and certainly in cases where chlorine is excluded. Another much disputed spectrum is that giving the bands which appear in the electric arc; it is most frequently ascribed to cyanogen, but occasionally also to carbon vapour.

Compounds generally show spectra of resolvable bands, and

if an elementary body shows a spectrum of the same type we are probably justified in assuming it to be due to a complex molecule. But that it may be given by the ordinary diatomic molecule is exemplified by oxygen, which gives in thick layers by absorption one of the typical sets of bands which were used by Deslandres and others to investigate the laws of distribution of frequencies. These bands appear in the solar spectrum as we observe it, but are due to absorption by the oxygen contained in the atmosphere.

If oxygen is rendered luminous by the electric discharge, a series of spectra may be made to appear. Under different conditions we obtain (*a*) a continuous spectrum most intense in the yellow and green, (*b*) the spectrum dividing itself into two families of series, (*c*) a spectrum of lines which appears when a strong spark passes through oxygen at atmospheric pressure, (*d*) a spectrum of bands seen in the kathode glow. We have therefore five distinct spectra of oxygen apart from the absorption spectra of ozone. To explain this great variability of spectroscopic effects we may either adopt the view that molecular aggregates of semi-stable nature may be found in vacuum tubes, or that a molecule may gain or lose one or more additional electrons and thus form new vibrating systems. It seemed that an important guide to clear our notions in this direction could be obtained through the discovery of J. Stark, who examined the spectra of the so-called "canal-rays" (*Canalestrahlen*). These rays are apparently the trajectories of positively charged particles having masses of the order of magnitude of the gaseous molecules. Stark discovered that in the case of the series spectrum of hydrogen and of other similar spectra the lines were displaced indicating high velocities; in other cases no displacements could be observed. The conclusion seemed natural that the spectra which showed the Doppler effect were due to vibratory systems which had an excess of positive charge. More detailed examinations of the "canal-rays" by J. J. Thomson and others have shown however that they contain both neutral and charged molecules in a relative proportion which adjusts itself continuously, so that even neutral molecules may partake of the translatory motion which they gained while carrying a charge. No conclusion can therefore be drawn, as Stark[1] has more recently pointed out, respecting the charge of the molecule which emits the observed spectrum. Nevertheless, the subject is well worth further investigation.

Previous to Stark's investigation P. Lenard[2] had concluded that the carriers of certain of the lines of the flame spectra of the alkali metals are positively charged. He draws a distinction between the lines of the trunk series to which he assigns neutral, and the lines of carriers the two branch series of which are electrically charged. The numerical relations existing between the trunk series and the branch series make it somewhat difficult to believe that they belong to different vibrating systems. But while we should undoubtedly hesitate on this ground to adopt Fredenhagen's[3] view that the two branch series belong to the element itself and the trunk series to a process of oxidation, we cannot press the argument against the view of Lenard, because the addition or subtraction of an electron introduces two vibrating systems which are still connected with each other and some numerical relationship is probable. Whatever ideas we may form on this point, the observations of Stark and Siegl[4] have shown that there is a Doppler effect, and therefore a positive charge, for one of the lines of the trunk series of potassium, and E. Dorn[5] has found the Doppler effect with a number of lines of helium, which contain representatives of the trunk series as well as of the two branch series. These facts do not countenance the view that there is an essential electric difference between the vibrating system of the three members of a family of series.

It is probable, however, that the above observations may help to clear up some difficulties in the phenomena presented by flames. While we have seen that the radiation of sodium vapour has an intensity corresponding to that of the pure thermal radiation at the temperature of the flame, other flames not containing oxygen (*e.g.* the flames of chlorine in hydrogen) do not apparently emit the usual sodium radiation when a sodium salt is placed in them. In the light of our present knowledge we should look for the different behaviour in the peculiarity of the oxygen flame to ionize the metallic vapour.

14. *Fluorescence and Phosphorescence.*—When a simple periodic force acts on a system capable of oscillatory motion the ultimate forced vibration has a period equal to that of the impressed force, but the ultimate state is only reached theoretically after an infinite time, and if meanwhile the vibrating system suffers any perturbations its free periods will at once assert themselves. Applying the reasoning to the case of a homogeneous radiation traversing an absorbing medium, we realize that the mutual disturbances of the molecules by collision or otherwise must bring in the free period of the molecule whatever the incident radiation may be. It is just in this degradation of the original period that (according to the present writer) the main phenomenon of absorption consists.[6] With most bodies the degradation goes on rapidly and the body mainly radiates according to its temperature, but there are cases in which these intermediate stages can be observed and the body seems then to be luminous under the influence of the incident radiation. Such bodies are said to be fluorescent, the degradation of motion towards that determined by its temperature gives rise to the law of Stokes, the fluorescent light being in nearly all cases of lower frequency than the incident light. With absorbing gases we should expect the degradation to proceed more slowly than with liquids, and hence the discovery of E. Wiedemann and Schmidt[7] that the vapours of sodium and potassium are fluorescent, important as it was from an experimental point of view, caused no surprise. It is not possible here to enter into a detailed description of the phenomena of fluorescence (*q.v.*), though their importance from a spectroscopic point of view has been materially increased through the recent researches of Wood[8] on the fluorescence of sodium vapour. After Wood and Moore had confirmed and extended the observations of Wiedemann and Schmidt and showed that the vibrating system of the fluorescent light seems identical with that observed by absorption in the fluted band spectrum, Wood excited the fluorescence by homogeneous radiation and discovered some remarkable facts. The fluorescent bands in this case appear to shift rapidly when the period of the incident vibration is altered, though the change may be small. The author, no doubt correctly, remarks that the shift does not indicate a change of frequency but a change of relative intensity, consisting of a great number of fine lines; when the maximum intensity of the distribution of light is altered, the appearance is that of a shift. It would probably not be difficult to imagine a mechanical system having a number of free periods which when set into motion by a forced vibration shows a corresponding effect. If the forced vibration is suddenly stopped, the free periods will appear but not necessarily with the same intensity when the period of the original forced vibration is altered. There cannot, however, be a question that, as R. W. Wood remarks, the careful investigation of these phenomena is likely to give us an insight into the mechanism of radiation.

Phosphorescence (*q.v.*) can only be here alluded to in order to draw attention to the *phenomena* studied by Sir William Crookes and others in vacuum tubes. When kathode rays strike certain substances, they emit a phosphorescent light, the spectroscopic investigation of which shows interesting effects which are important especially as indicating the influence of slight admixtures of impurities on the luminescence. It should be mentioned that the infra-red rays have a remarkable damping effect on the phenomena of phosphorescence, a fact which has

been made use of by Becquerel in his investigations of infra-red radiations.

15. *Relationship between the Spectrum of an Element and that of its Compounds.*—In the present state of our knowledge we cannot trace any definite relationship between the spectrum of a compound body and that of its elements, and it does not even seem certain that such a relationship exists, but there is often a similarity between different compounds of the same element. The spectra, for instance, of the oxides and haloid salts of the alkaline earths show great resemblance to each other, the bands being similar and similarly placed. As the atomic weight of the haloid increases the spectrum is displaced towards the red.

It is in the case of the absorption spectra of liquids that we can most often discover some connexion between vibrations of a complex system and that of the simpler systems which form the complex. The most typical case in this respect is the effect of a solvent on the absorption spectrum of a solution. A. Kundt,[1] who initiated this line of investigation, came to the conclusion that the absorption spectra of certain organic substances like cyanin and fuchsin were displaced towards the red by the solvent, and that the displacement was the greater the greater the dispersive power of the solvent. This law cannot be maintained in its generality, but nevertheless highly dispersive substances like carbon bisulphide are always found to produce a greater shift than liquids of smaller dispersion like water and alcohol. In these cases the solvent seems to act like an addition to the mass of the vibrating system, the quasi-elastic forces remaining the same.

Dr J. H. Gladstone,[2] at an early period of spectroscopy, examined the absorption spectra of the solution of salts, each constituent of which was coloured. He concluded that generally but not invariably the following law held good: "When an acid and a base combine, each of which has a different influence on the rays of light, a solution of the resulting salt will transmit only those rays which are not absorbed by either, or, in other words, which are transmitted by both." He mentioned as an important exception the case of ferric ferrocyanide, which, when dissolved in oxalic acid, transmits the rays in great abundance, though the same rays be absorbed both by ferrocyanides and by ferric salts. Soret has confirmed, for the ultra-violet rays, Dr Gladstone's conclusions with regard to the identity of the absorption spectra of different chromates. The chromates of sodium, potassium and ammonium, as well as the bichromates of potassium and ammonium, were found to give the same absorption spectrum. Nor is the effect of these chromates confined to the blocking out simply of one end of the spectrum, as in the visible part, but two distinct absorption bands are seen, which seem unchanged in position if one of the above-mentioned chromates is replaced by another. Chromic acid itself showed the bands, but less distinctly, and Soret does not consider the purity of the acid sufficiently proved to allow him to draw any certain conclusions from this observation.

In many of these cases the observed facts might perhaps be explained by dissociation, the undissociated compound producing no marked effect on the spectra. In 1872 W. N. Hartley and A. K. Huntingdon examined by photographic methods the absorption spectra of a great number of organic compounds. The normal alcohols were found to be transparent to the ultra-violet rays, the normal fatty acids less so. In both cases an increased number of carbon atoms increases the absorption at the most refrangible end. The fact that benzene and its derivatives are remarkable for their powerful absorption of the most refrangible rays, and for some characteristic absorption bands appearing on dilution, led Hartley to a more extended examination of some of the more complicated organic substances. He determined that definite absorption bands are only produced by substances in which three pairs of carbon atoms are doubly linked together, as in the benzene ring. Subsequently[3] he subjected the ultra-violet absorption of the alkaloids to a careful investigation, and arrived at the conclusion that the spectra are sufficiently characteristic to "offer a ready and valuable means of ascertaining the purity of the alkaloids and particularly of establishing their identity."

[1] *Wied. Ann.* (1878), 4, p. 34.
[2] *Phil. Mag.* (1857), 14, p. 418.
[3] *Phil. Trans.* (1885), pt. ii.

We can only briefly refer to an important investigation of Sir William Abney and Colonel E. R. Festing, who examined the infra-red absorption of a number of substances. We may quote one of the principal conclusions at which they arrived:—

"An inspection of our maps will show that the radical of a body is represented by certain well-marked bands, some differing in position according as it is bonded with hydrogen, or a halogen, or with carbon, oxygen or nitrogen. There seem to be characteristic bands, however, of any one series of radicals between 1000 and about 1100, which would indicate what may be called the central hydrocarbon group, to which other radicals may be bonded. The clue to the composition of a body, however, would seem to lie between 700 and 1000. Certain radicals have a distinctive absorption about 700 together with others about 900, and if the first be visible it almost follows that the distinctive mark of the radical with which it is connected will be found. Thus in the ethyl series we find an absorption at 740, and a characteristic band, one edge of which is at 892 and the other at 920. If we find a body containing the 740 absorption and a band with the most refrangible edge commencing at 892, or with the least refrangible edge terminating at 920, we may be pretty sure that we have an ethyl radical present. So with any of the aromatic group; the crucial line is at 867. If that line be connected with a band we may feel certain that some derivative of benzene is present. The benzyl group shows this remarkably well, since we see that phenyl is present, as is also methyl. It will be advantageous if the spectra of ammonia, benzene, aniline and dimethyl aniline be compared, when the remarkable coincidences will at once become apparent, as also the different weighting of the molecule. The spectrum of nitrobenzene is also worth comparing with benzene and nitric acid. In our own minds there lingers no doubt as to the easy detection of any radical which we have examined, . . . and it seems highly probable by this delicate mode of analysis that the hypothetical position of any hydrogen which is replaced may be identified, a point which is of prime importance in organic chemistry. The detection of the presence of chlorine or bromine or iodine in a compound is at present undecided, and it may be well that we may have to look for its effects in a different part of the spectrum. The only trace we can find at present is in ethyl bromide, in which the radical band about 900 is curtailed in one wing. The difference between amyl iodide and amyl bromide is not sufficiently marked to be of any value."

The absorption spectra of cobalt and didymium salts also offer many striking examples of minor changes produced in spectra by combination and solution. (A. S.*)

Apparatus.—Spectroscopes may be divided into two classes: prism spectroscopes, with angular or direct vision, and grating spectroscopes; the former acting by refraction (*q.v.*), the latter by diffraction or interference. Angular prism spectroscopes are the commonest. Such an instrument consists of a triangular prism set with its refracting edge vertical on a rigid platform attached to a massive stand. The prism may be made of a dense flint glass or of quartz if the ultra-violet is to be explored, or it may be hollow and filled with carbon bisulphide, α-bromnaphthalene or other suitable liquid. Liquid prisms, however, suffer from the fact that any change of temperature involves a change in the refractive index of the prism. The stand carries three tubes: the collimator, observing telescope and scale telescope. The collimator has a vertical slit at its outer end, the width of which may be regulated by a micrometer screw; in some instruments one half of the slit is covered by a small total reflection prism which permits the examination of two spectra simultaneously. At the other end of the collimator there is a condensing lens for bringing the rays into parallelism. The observing telescope is of the ordinary terrestrial form. The scale telescope contains a graduated scale which is illuminated by a small burner; the scale is viewed by reflection from the prism face opposite the first refracting face. The power may be increased, but with a diminution of intensity, by using a train of prisms. Steinheil made an instrument of four prisms, each of which had, however, to be set in the position of minimum deviation by trial. In Browning's form the setting is automatic. The dispersion may be further increased by causing the rays to pass more than once through the prism or prisms. Thus, by means of a system of reflecting prisms, Hilger passed the dispersed rays six times through one prism, and, by similar means, Browning passed the rays first through the upper part of a train and then back through the lower part. Compound prisms are also employed. Rutherfurd devised one made of flint glass with two crown glass compensating prisms; whilst Thallon employed a hollow prism containing carbon bisulphide also compensated by flint glass prisms. In direct vision spectroscopes the refracting prisms and slit are in the observing telescope. The prisms are necessarily compound, and usually consist of flint glass with compensating prisms of crown. In all cases where compound prisms are used, the angles must be accurately calculated. Amici in 1860 devised such an instrument; an improved form by Jannsen was made up of two flint and three crown prisms, and in Browning's form there are three flint and four crown. Sorby and, later, Abbe, designed instruments on the same principle to be used in connexion with the microscope. By suitably replacing the ocular of the observing telescope in an angular vision spectroscope by a photographic camera, it is possible to photograph spectra; such instruments are termed spectrographs. In grating spectroscopes both plane and concave gratings are employed in connexion with a collimator and observing telescope.

SPECULATION, a round game of cards at which any reasonable number can play. Each player contributes a stake to the pool, the dealer staking double. Three cards are dealt face downwards to each player; the top card of those left is turned up for trumps. Each player, beginning with the player on the dealer's left, turns up a card; if it is not a trump, or is a lower trump than the trump-card, the next player turns up one of his cards, and so on till a higher trump than the trump-card appears, the values being reckoned as at whist. The holder may sell this card to the highest bidder, or retain it. The turning-up proceeds till a still higher trump is found, but the holder of the original highest does not turn up till his card is beaten. The new card may then be sold. The dealer may not turn up till the trump-card has been beaten. The holder of the highest trump when all the hands have been exposed takes the pool. If the ace of trumps is the trump-card, the dealer takes the pool; if it is turned up during play, the hand is, of course, at an end. Variations of the game allow the purchase of unseen cards or hands, or of the trump-card, even before it is turned up. The cards used in one deal are not dealt again till the whole pack has been gradually dealt out; they are collected and shuffled by the "pone"—the player on the dealer's right—to be used when the pack is exhausted.

SPECULUM, the Latin word for a mirror, employed more particularly for a metallic mirror used in a reflecting telescope. In early instruments metallic mirrors, made from an alloy of copper and tin, with the addition of a little arsenic or other metals to increase the whiteness, were customarily employed, but they have now been displaced by the more convenient silver-on-glass mirror (see TELESCOPE). Various forms of specula are used in surgery for examining internal organs.

SPEDDING, JAMES (1808–1881), English author, editor of the works of Bacon, was born on the 26th of June 1808, in Cumberland, the younger son of a country squire. He was educated at Bury St Edmunds and Trinity College, Cambridge, where he took a second class in the classical tripos, and was junior optime in mathematics in 1831. In 1835 he entered the colonial office, but he resigned this post in 1841. In 1842 he was secretary to Lord Ashburton on his American mission, and in 1855 he became secretary to the Civil Service Commission; but from 1841 onwards he was constantly occupied in his researches into Bacon's life and philosophy. On the 1st of March 1881 he was knocked down by a cab in London, and on the 9th he died of erysipelas. His great edition of Bacon was begun in 1847 in collaboration with R. E. Ellis and D. D. Heath. In 1853 Ellis had to leave the work to Spedding, with the occasional assistance of Heath, who edited most of the legal writings. The *Works* were published in 1857–1859 in seven volumes, followed by the *Life and Letters* (1861–1874). Taken together these works contain practically all the material which exists in connexion with the subject, collected and weighed with the utmost care and impartiality. Spedding humorously emphasized his devotion to Bacon in the title of one of his non-Baconian works, *Reviews and Discussions, Literary, Political and Historical, not relating to Bacon* (1879); and his literary remains outside that one field are no longer of interest. But as a Baconian scholar he is not likely soon to be superseded.

SPEED, JOHN (1552–1629), English historian and cartographer, was born, according to Fuller, at Farringdon, Cheshire. He was the son of a London tailor, and followed his father's trade, being admitted member of the Merchant Taylors Company in 1580. He settled in Moorfields, where he built himself a house. He was enabled to give up his trade and to devote himself to antiquarian pursuits through the kindness of Sir Fulke Greville, whom Speed calls the "procurer of my present estate," and through his patron's interest he also received a "waiter's room in the custom-house." The results of the leisure thus secured to him appeared in 1611 in his *Theatre of the Empire of Great Britaine*, a series of fifty-four maps of different parts of England, which had already appeared separately, and in which he was helped by Christopher Saxton, John Norden and William White. To each map descriptive matter was attached. In 1611 also he published his *History of Great Britaine under the Conquests of the Romans . . . to . . . King James*. Speed acknowledges his obligations to the chief antiquaries and historians of his day. Sir Robert Cotton lent him manuscripts and coins, and is said to have revised the proofs for him; in heraldry he acknowledges the help of William Smith (1550?–1618); and he had valuable help from John Barkham (1572?–1642) and Sir Henry Spelman. Speed brought some historical skill to bear on the arrangement of his work, and although he repeated many of the errors of older chroniclers he added valuable material for the history of his country. He died in London on the 28th of July 1629.

Other maps of his, beside those in the *Theatre*, are in the British Museum. Another edition of the *Theatre* is *Theatrum Magnae Britanniae latine*, redditum a P. Holland (London, folio, 1616). He wrote *Genealogies Recorded in Sacred Scriptures* (1611), and a similar work, *A Cloud of Witnesses* (1616). These passed through numerous editions, and were frequently prefixed to copies of the Bible. An account of Speed's descendants is to be found in Rev. J. S. Davies's *History of Southampton* (1883), which was founded on MS. material left by John Speed (1703–1781).

SPEETON BEDS, in English geology, a series of clays well exposed at Speeton, near Filey on the Yorkshire coast. Peculiar interest attaches to these beds for they are the principal representatives in Britain of the marine phase of the Lower Cretaceous system. The Speeton Clays pass downwards without break into the underlying Kimeridgian; they are capped by the Red Chalk, which may be regarded as the equivalent of the Upper Gault of southern England. These beds thus form a passage series between *marine* Jurassic strata and those belonging undoubtedly to the Cretaceous system; in this way they correspond with the Purbeck-Wealden rocks, which form a connecting link between *estuarine* Jurassic and Cretaceous strata.

Above the dark, bituminous, nodular shales with Kimeridge fossils at the base of the Speeton Clay comes the zone of *Belemnites lateralis* (34 ft.), with *Olcostephanus gravesiformis, O. rotula*, and species of *Hoplites* and *Oxynoticeras*; this is followed by the zone of *Belemnites jaculum*, with *B. cristatus*, *Olcostephanus* (*Astieria*) *astieri*, *O.* (*Simbirskites*) *inversus* and *O.* (*S.*) *Speetonensis* in ascending order; *Echinospatagus cordiformis*, a species found in the typical Neocomian area, also occurs in this zone. The next higher zone is that of *Belemnites brunsvicensis* (=*semicanaliculatus*) (100 ft.), with *B. Speetonensis, Hoplites deshayesii*, and *Amaltheus bicurvatus*. The topmost zone is characterized by *Belemnites minimus* with *Inoceramus concentricus* and *I. sulcatus*; it consists of a few feet of mottled clays. It appears, therefore, that while the lower portions of the Speeton Clay are the equivalents of the Wealden and perhaps of the Purbeck beds, the higher portions are the equivalents of the Lower Greensand and part of the Gault. In Lincolnshire the upper Speeton beds are represented by the Carstone and Tealby Limestone and Clay, and the lower Speeton by the Claxby Ironstone, Spilsby Sandstone and lower part of the Tealby clay. A similar faunal horizon is recognized in Heligoland and Russia.

SPEKE, HUGH (1656–*c.* 1724), English writer and agitator, was a son of George Speke (d. 1690) of White Lackington, Somerset. The older Speke was a member of the Green Ribbon Club, the great Whig organization which was founded in 1675, and was a supporter of the duke of Monmouth, voting for the Exclusion Bill in 1681. Educated at St John's College, Oxford, Hugh Speke joined the Green Ribbon Club, and in 1683 he was put in prison for asserting that Arthur Capell, earl of Essex, another of Monmouth's supporters, had been murdered by the friends of the duke of York. He was tried and sentenced to pay a fine, but he refused to find the money, and remained in prison for three years, being in captivity during Monmouth's rebellion, in consequence of which his brother Charles was hanged at Ilminster. In prison Speke kept a printing-press, and from this he issued the *Address to all the English Protestants in the Present Army*, a manifesto written by the Whig divine Samuel Johnson (1649–1703), urging the soldiers to mutiny. In 1687 he was released, and in 1688 he served James II. as a spy in the camp of William of Orange. In December of this year a document, apparently official, was found by a London bookseller. This called upon the Protestants to disarm their Roman Catholic neighbours; it was freely circulated, and much damage was done to property in London before it was found that it was a forgery. It appears to have been the work of Speke, although this was not known until 1709, when he asserted his authorship in his *Memoirs of the Most Remarkable Passages and Transactions of the Revolution*. He afterwards issued these memoirs with modifications as *The Secret History of the Happy Revolution in 1688* (1715). After imploring both Anne and George I. to reward his past services, Speke died in obscurity before 1725.

SPEKE, JOHN HANNING (1827–1864), English explorer, discoverer of the source of the Nile, was born on the 4th of May 1827 at Jordans near Ilminster, Somersetshire. On his father's side he descended from the ancient Yorkshire family of Espec, a branch of which migrated to Somerset in the 15th century. His mother was a Miss Georgina Hanning, of Dillington Park, Somerset. Through his mother's influence with the duke of Wellington he obtained a commission in the Indian Army, which he entered in 1844. He served in Sir Colin Campbell's division in the Punjab campaigns, and acquired considerable repute both as a soldier and as a sportsman and naturalist. When on furlough Captain Speke had explored portions of the Himalayas, had crossed the frontier into Tibet and mapped part of its south-western districts; but his attention was at an early date turned to the great problems of African geography, and in 1854 he began his brief and brilliant African career by joining Captain (afterwards Sir) Richard Burton in an expedition into the interior of Somaliland, the incidents of which are narrated in *What led to the Discovery of the Source of the Nile* (London, 1864). In April 1854 the expedition was attacked by Somalis near Berbera, one officer being killed, Burton slightly, and Speke severely wounded. Invalided home, Speke shortly afterwards volunteered for the Crimea and served during the war with a regiment of Turks. In 1856 he accepted an invitation from Burton to join an expedition to verify the reports as to the existence of great lakes in east central Africa, and especially to try and find Lake Nyassa. The route to Nyassa was closed by the Arabs, and the travellers left Zanzibar in June 1857 by a more northerly route, which brought them by November to a place called Kazé in Unyamwezi. Here they learnt from an Arab trader that further inland were three great lakes—and Speke leapt to the conclusion that the most northerly of the three would prove to be the source of the Nile. Continuing westward in January 1858 the travellers reached Lake Tanganyika, of which they made a partial exploration, Speke marking on his map the mountains which close in the lake to the north, "Mountains of the Moon." By June they were back at Kazé, and here Speke induced his chief, who was ill, to allow him to attempt to reach the northern lake. Marching north for twenty-five days, on the 30th of July Speke reached a creek, along which he travelled till, on the 3rd of August, he saw it open up into the waters of a lake extending northward to the horizon. He no longer doubted that this lake—the Victoria Nyanza—was the source of the Nile. Returning to Kazé (August 25) he made known his discovery to Burton, who did not believe Speke's theories. The explorers reached Zanzibar early in 1859, Speke hastened back to England in advance of his comrade, and at once made public his discoveries and conclusions. Despite the scepticism of his fellow traveller and many geographers, he secured the support of Sir Roderick Murchison, president of the Royal Geographical Society, under whose direction a new expedition, expressly intended to solve the Nile problem, was fitted out. Of this expedition Speke had the command, his only European companion being Captain (afterwards Colonel) J. A. Grant (*q.v.*). The expedition, over 200 men all told, started from Zanzibar in October 1860 and reached Kazé on the 24th of January 1861. Despite illness and the hostility and extortions of the natives the Victoria Nyanza was again reached, at its south-west corner, in October 1861. Following the western shores of the lake Speke crossed the Kagera on the 16th of January 1862, and arrived at the capital of Uganda on the 19th of February following. Here he was detained by the king, Mtesa, for some months, but at last prevailed on the chief to furnish him with guides, and on the 28th of July Speke stood at the spot where the Nile issued from the lake. The great discovery was made, the problem which had baffled all previous efforts—extending over 2000 years—was solved. The troubles of the travellers were, however, by no means over; with difficulty they obtained permission to enter Unyoro, and with difficulty were allowed to leave, without being permitted to visit another large lake (the Albert Nyanza) of whose existence and connexion with the Nile they learned. As far as possible Speke and Grant followed the course of the Nile, and on the 3rd of December came in touch with the outside world once more, striking in 3° 10′ 37″ N. an outpost established at the request of John Petherick, British consul at Khartum, who had been charged with a mission for the relief of the explorers. On the 15th of February 1863 they arrived at Gondokoro, the Egyptian post on the Nile marking the limit of navigability from the north. At Gondokoro they met Sir Samuel (then Mr) Baker, generously giving him the information which enabled him to discover the Albert Nyanza. From Khartum Speke telegraphed to London the great news that the Nile had been traced to its source, and on his return to England he was received with much enthusiasm. In the same year (1863) he published his *Journal of the Discovery of the Source of the Nile*, a work full of geographical, ethnological and zoological information, and written in a frank, attractive style. The accuracy of his observations and the correctness of his main deductions have been since abundantly justified. But as Speke had not been able to follow the Nile the whole way from the Victoria Nyanza to Gondokoro, and as the part played in the Nile régime by the Albert Nyanza was then unknown, Burton and others remained unconvinced, and Speke's conclusions were criticized in *The Nile Basin* (1864), a joint production of Burton and James McQueen; it being argued in this work that Tanganyika was the true Nile source. It was arranged that Speke should meet Burton at the meeting of the geographical section of the British Association at Bath on the 16th of September and publicly debate the question of the Nile source. On the previous afternoon Speke was out partridge shooting at Box, near Bath. In getting over a low stone wall he laid down his gun at half cock. Drawing the weapon towards him by the muzzle one barrel exploded and entered his chest, inflicting a wound from which Speke died in a few minutes. A granite obelisk to his memory was erected by public subscription in Kensington Gardens.

See, besides the works mentioned, Sir R. F. Burton, *The Lake Regions of Central Africa* (London, 1860); J. A. Grant, *A Walk across Africa* (London, 1864); T. D. Murray and A. S. White, *Sir Samuel Baker: a Memoir* (London, 1895); *The Times* (Sept. 17 and 19, 1864); Sir H. H. Johnston, *The Nile Quest* (London, n. d. [1903]).

SPELLING BEE, a match in which two sides contest in accuracy of spelling. The custom, an old one, was revived in the schools of the United States about the year 1873, and rapidly spread throughout the country and to Great Britain, enjoying for a few years an extraordinary vogue, not only in schools, but in all classes and ages of society. In the United States inter-city and inter-state matches were not unknown. According to the generally recognized rules a competitor who misspelled a word retired, and the match was won by the side having the greatest number of survivors at the close. The use of the word "bee" as an assemblage of persons for the purpose of joint work or play originated in America in colonial times, and was taken from the labour of the bees of a hive. Familiar examples of it are *husking-bee* and *quilting-bee*, assemblages of villagers for the purpose of helping a neighbour with the husking of the corn or his wife with her quilt-making.

SPELLO (anc. *Hispellum, q.v.*), a town of Umbria, in the province of Perugia, from which it is 22 m. S.E. by rail, 1030 ft. above sea-level. Pop. (1901), 5571. It is picturesquely situated on the slope of a mountain. The Cappella Baglioni in the church of S. Maria Maggiore contains some of Pinturicchio's finest frescoes (1501), "The Annunciation," "The Adoration" and "Christ in the Temple." The rich background with gold decoration in relief is characteristic. There is also a late altarpiece by Perugino (1521) and a fine early Renaissance canopy by Rocco da Vicenza (1515). In the sacristy is a crucifix in silver by Paolo Vanni of Perugia (1398). The holy-water basin is formed of a sepulchral *cippus* of the Roman period. S. Andrea contains a large altarpiece by Pinturicchio (1508), upon which a letter from G. Baglioni to the artist is painted.

See G. Urbini, in *L'Arte* (1897), ii. 367 sqq., (1898), iii. 16 sqq.

SPELMAN, SIR HENRY (*c.* 1564–1641), English antiquary, was the eldest son of Henry Spelman, of Congham, Norfolk, and the grandson of Sir John Spelman (*c.* 1495–1544), judge of the king's bench. Born probably in 1564, he was educated at Walsingham School, and proceeded in 1580 to Trinity College, Cambridge, where he took his degree in 1583. His father had died in 1581, and on Spelman devolved the management of the family estates. He became a member of Lincoln's Inn, but in 1590 he returned to Norfolk, where he married Eleanor l'Estrange. He became guardian to his brother-in-law, Sir Hamon l'Estrange, on whose property at Hunstanton he resided for some time. He occupied himself with the history and antiquities of his native county, writing an account of Norfolk for John Speeds's *Theatre of Great Britaine*. He belonged to the Society of Antiquaries, of which Sir Robert Cotton and William Camden were also members. The society gradually declined, and Spelman's efforts to revive it in 1614 were frustrated by James I. Having bought in 1594 the remainder of the two leases of two abbeys of which the Crown was the lessor, he became involved in prolonged litigation over them, and a judgment given against him by Bacon makes it interesting to find Spelman subsequently among the petitioners who alleged corruption against the lord chancellor. His experience in this process no doubt combined with a scandal connected with a church and parsonage in the possession of his uncle Francis Sanders to occasion his pamphlet *De non temerandis ecclesiis* (1613–1616), which induced many lay owners of ecclesiastical spoils to make restitution, and Spelman himself acted accordingly. This tract led up to his *History and Fate of Sacrilege*,[1] which was in the hands of the printer when the Great Fire broke out. The book was supposed to have perished, but Bishop Gibson discovered part of it in the Bodleian Library. It was printed, not, however, under his editorship, in 1698, with the statement on the title-page that it was "wrote in 1632." Spelman had conceived the idea of a work on the foundations of English law, based on early charters and records, but finding that there were no adequate means of determining the exact meaning of the Anglo-Saxon and Latin law terms employed in the documents, he began to compile a glossary, the first volume of which, *Archaeologus in modum glossarii*, was published at his own expense in 1626. He continued to work at the subject until 1638. A second volume, *Glossarium archaiologicum* (1664), appeared after his death. His *Codex legum veterum statutorum regni Angliae, quae ab ingressu Gulielmi I usque ad annum nonum Henry III. edita sunt* was published by David Wilkins in his *Leges anglo-saxonicae* (1721). Spelman's most important work, *Concilia, decreta, leges, constitutiones in re ecclesiarum orbis britannici*, is an attempt to place English church history on a basis of genuine documents. The first volume, which occupied him seven years, came down to 1066 and was published in 1636. A second volume was edited by Sir William Dugdale in 1664. Spelman entered parliament as member for Castle Rising in 1597, and in 1604 was high sheriff of his county. In 1612 he settled in London near his friend Sir Robert Cotton. In 1617 he served on a commission to inquire into disputed Irish estates, and later took part in three legal inquiries into the exactions levied on behalf of the Crown in the civil and ecclesiastical courts. He was member of parliament for Worcester in 1625. In 1627 he became treasurer of the Guiana Company, and he was also an energetic member of the council for New England. His general services to the state were recognized in 1636 by a gift of money, and two years later by the offer of the mastership of Sutton's Hospital, Charterhouse. He died in London in October 1641, and was buried in Westminster Abbey. His later years had been spent in the house of his son-in-law, Sir Ralph Whitfield.

His son, Sir John Spelman (1594–1643), also gained a reputation as a scholar and antiquary. He was knighted in 1641 and served the king actively at the beginning of the Civil War. He edited from MSS. in his father's library *Psalterium Davidis latino-saxonicum vetus* (1640), and wrote a Life of Alfred the Great which was translated into Latin and published in 1678.

Edmund Gibson, bishop of London, published in 1723 *The English Works of Sir Henry Spelman, Kt., Published in his Lifetime; together with his Posthumous works relating to the Laws and Antiquities of England*. The first section contained *De non Temerandis Ecclesiis*, already mentioned; *The Larger Treatise concerning Tythes*, first published in 1646; *De sepultura*; and *Villare anglicum, or a View, of the Towns of England*; while the second included *The Original, Growth, Propagation and Condition of Feuds and Tenures by Knight-service in England*, written in 1639; *Two Discourses*: *i. Of the Ancient Government of England, ii. Of Parliaments*; *The Original of the Four Terms of the Year*, written in 1614 and first printed in 1684; *Icenia*: a Latin description of Norfolk, and some other treatises. This was a revised edition of an earlier collection (1698), and contained a life of the author, based chiefly on the autobiographical matter prefixed to the Glossary of 1626, and two additional papers, *Of the Admiral Jurisdiction, and the Officers thereof*, and *Of Antient Deeds and Charters*. Wilkins's edition of his *Concilia* was edited by A. W. Haddan and W. Stubbs in 1869–1873.

SPENCE, THOMAS (1750–1814), inventor of a system of land nationalization, was born at Newcastle-on-Tyne on the 21st of June 1750, the son of a Scottish netmaker and shoemaker. A dispute in connexion with common land rights at Newcastle impelled him to the study of the land question. His scheme was not for land nationalization proper, but for the establishment of self-contained parochial communities, in which rent paid to the corporation, in which the absolute ownership of the land was vested, should be the only tax of any kind. His pamphlet, *The Meridian Sun of Liberty*, which was first hawked in Newcastle, appeared in London in 1793; it was reissued by Mr H. M. Hyndman under the title of *The Nationalization of the Land in 1775 and 1882*. Spence presently left Newcastle for London, where he kept a bookstall in High Holborn. In 1784 he spent six months in Newgate gaol for the publication of a pamphlet distasteful to the authorities, and in 1801 he was sentenced to twelve months' imprisonment for seditious libel in connexion with his pamphlet entitled *The Restorer of Society to its Natural State*. He died in London on the 8th of September 1814. His admirers formed a "Society of Spencean Philanthropists," of which some account is given in Harriet Martineau's *England During the Thirty Years' Peace*.

See also Davenport, *Life, Writings and Principles of Thomas Spence* (London, 1836).

SPENCER, HERBERT (1820–1903), English philosopher, was born at Derby on the 27th of April 1820. His father, William George Spencer, was a schoolmaster, and his parents' religious convictions familiarized him with the doctrines of the

[1] This was re-edited as late as 1895, with an appendix bringing the subject up to date, by C. F. S. Warren.

Methodists and Quakers. He declined an offer from his uncle, the Rev. Thomas Spencer, to send him to Cambridge, and so was practically self-taught. During 1837–1846 he was employed as an engineer on the London & Birmingham railway; 1848–1853 as sub-editor of the *Economist*. From about this time to 1860 he contributed a large number of articles to the *Westminster Review*, which contain the first sketches of his philosophic doctrines. He also published two larger works, *Social Statics* in 1850, and *Principles of Psychology* in 1855. In 1860 he sent out the syllabus of his *Synthetic Philosophy* in ten volumes, and in spite of frequent ill health had the satisfaction of completing it in 1896 with the third volume of the *Principles of Sociology*. He died on the 8th of December 1903.

Herbert Spencer's significance in the history of English thought depends on his position as the philosopher of the great scientific movement of the second half of the 19th century, and on the friendship and admiration with which he was regarded by men like Darwin, G. H. Lewes and Huxley. Spencer tries to express in a sweeping general formula the belief in progress which pervaded his age, and to erect it into the supreme law of the universe as a whole. His labours coincided in time with the great development of biology under the stimulus of the Darwinian theory, and the sympathizers with the new views, feeling the need of a comprehensive survey of the world as a whole, very widely accepted Spencer's philosophy at its own valuation, both in England and, still more, in America. In spite of this, however, his heroic attempt at a synthesis of all scientific knowledge could not but fall short of its aim. Living at the commencement of an epoch of unparalleled scientific activity, Spencer could not possibly sum up and estimate its total production. To the specialists in sciences which were advancing rapidly and in divergent directions to results which often reacted on and transformed their initial assumptions, Spencer has often appeared too much of a philosopher and defective in specialist knowledge. To the technical philosophers, who strictly confine themselves to the logical collation and criticism of scientific methods, he has, contrariwise, not seemed philosophic enough. Hence his doctrines were open to damaging attacks from both sides, the more so as he always stood aloof from the academic spirit and its representatives. It seems unlikely, therefore, that as a system the *Synthetic Philosophy* will prove long-lived; but this hardly detracts from its fruitfulness as a source of suggestion, or from the historic influence of many of its conceptions on the culture of the age.

This estimate of Spencerian philosophy may be substantiated by a brief survey of its origin and leading characteristics. Spencer claims, with some reason, that he was always an evolutionist. But his notions of what "evolution" is developed quite gradually. At first he seems to have meant by the word only the belief that progress is real, and that the existing order of nature is the result of a gradual process and not of a "special creation." In *Social Statics* (1850) he still regards the process teleologically, and argues after the fashion of Paley that "the greatest happiness is the purpose of creation" (ch. iii. § 1), and that to "gag the moral sentiment" is "to balk creative design" (ch. xxxii. § 7). But this phraseology soon disappears, without his considering how, in default of some sort of teleology, it is legitimate to treat the world's history as a process. In *The Development Hypothesis* (1852) he objects strongly to the incredibility of the special creation of the myriad forms of life, without, however, suggesting how development has been effected. In *Progress, its Law and Cause* (1857) he adopted Von Baer's law, that the development of the individual proceeds from the homogeneous to the heterogeneous. This is at once connected with the nebular hypothesis, and subsequently "deduced" from the ultimate law of the "persistence of force," and finally supplemented by a counter-process of dissolution, all of which appears to Spencer only as "the addition of Von Baer's law to a number of ideas that were in harmony with it." It is clear, however, that Spencer's ideas as to the nature of evolution were already pretty definite when Darwin's *Origin of Species* (1859) revolutionized the subject of organic evolution by adding natural selection to the direct adaptation by use and disuse, and so suggesting an intelligible method of producing modifications in the forms of life. Spencer welcomed the Darwinian theory, and enriched it with the phrase "survival of the fittest"; but he did not give up the (Lamarckian) belief in the hereditary transmission of the modifications of organisms by the exercise of function. Shortly afterwards (1860) he sent out the prospectus of a systematic exposition of his *Synthetic Philosophy*, of which the first volume, *First Principles*, appeared in 1862. This work is divided into two parts; the first intended to show that while ultimate metaphysical questions are insoluble they compel to a recognition of an inscrutable Power behind phenomena which is called the Unknowable; the second devoted to the formulation and illustration of the Law of Evolution. In the first part Spencer's argument rests on Mansel's *Limits of Religious Thought* and Hamilton's "philosophy of the conditioned" (and so ultimately on Kant), and tries to show that alike in scientific and religious thought the ultimate terms are "inconceivable" (not by him distinguished from "unimaginable"). In science, the more we know the more extensive "the contact with surrounding nescience." In religion the really vital and constant element is the sense of mystery. This is illustrated by the difficulties inherent in the conception of Cause, Space, Time, Matter, Motion, the Infinite, and the Absolute, and by the "relativity of knowledge," which precludes knowledge of the Unknowable, since "all thinking is relationing." Yet the Unknowable may exist, and we may even have an "indefinite knowledge" of it, positive, though vague and extralogical. Hence both science and religion must come to recognize as the "most certain of all facts that the Power which the Universe manifests to us is utterly inscrutable." Thus to be buried side by side in the Unknowable constitutes their final reconciliation, as it is the refutation of irreligion which consists of "a lurking doubt whether the Incomprehensible is really incomprehensible."

Such are the foundations of Spencer's metaphysic of the Unknowable, to which he resorts in all the fundamental difficulties which he subsequently encounters. Whatever its affinities with that version of "faith" which regards it as antagonistic to knowledge, it can hardly be deemed philosophically satisfactory. A failure to solve the problems of metaphysics must always remain a failure, in spite of all protestations that it was inevitable; and it in no wise justifies an advance to so self-contradictory an *asylum ignorantiae* as the Unknowable. In the edition of his *First Principles*, published in 1900, Spencer adds a "postscript" which shows some consciousness of the contradiction involved in his knowledge of the Unknowable, and finally contends that his account of the Knowable in part ii. will stand even if part i. be rejected. Even this, however, understates the case, seeing that a really inscrutable Unknowable would destroy all confidence in the order of nature and render all knowledge entirely precarious.

In part ii. Spencer recognizes successively likenesses and unlikenesses among phenomena (the effects of the Unknowable), which are segregated into manifestations, vivid (object, non-ego) or faint (subject, ego), and then into space and time, matter and motion and force, of which the last is symbolized for us by the experience of resistance, and is that out of which our ideas of matter and motion are built. Hence the Persistence of Force is the ultimate basis of knowledge. From it Spencer proceeds to deduce the indestructibility of matter and energy, the equivalence and transformation of forces, the necessity of a rhythm, of Evolution (*i.e.* integration of matter with concomitant dissipation of motion) and Dissolution, and finally reaches the statement of the Law of Evolution as "an integration of matter and concomitant dissipation of motion, during which the matter passes from an indefinite incoherent homogeneity to a definite coherent heterogeneity, and during which the retained motion undergoes a parallel transformation." This process of evolution is due to "the instability of the homogeneous," the "multiplication of effects" and their "segregation," continuing until it ceases in complete "equilibration." Sooner or later, however, the reverse process of Dissolution, with its absorption of motion and disintegration of matter, which indeed has always been going on to some extent, must prevail, and these oscillations of the cosmic process will continue without end.

It appears, therefore, that Spencer ultimately describes the Knowable in terms of the mechanical conceptions of matter and motion, and that this must give a materialistic colouring to his philosophy. There are, however, other flaws also in his procedure. The presence of Force, *i.e.* his version of the methodological assumption of constancy in the quantitative aspects of phenomena, seems a very unsuitable basis for a philosophy of progress. To such a philosophy a consideration of the conditions, if any, under which progress can be conceived as ultimately real, seems a necessary preliminary, which Spencer omits. He also assumes that "Evolution" is a real, nay, an ultimate law of nature, but his evidence only goes to show that it is a result, in some cases, of the complex interaction of laws, which, like Rhythm, Segregation, &c., are in their turn only tendencies, and may be, and often are, counteracted. By the afterthought of a "dissolution" process (2nd ed. of *First Principles*) Spencer in a way admits this, but introduces fresh difficulties as to its relation to "Evolution." If the two processes go on together both are tendencies, and whether there is on the whole progress or not will depend on their relative strength; neither can be universal, nor the "law" of cosmic existence, unless its coexisting rival is regarded as essentially secondary. But if so it ceases to be available as evidence of a coming reversal of the dominant process. If, on the other hand, the processes are strictly alternative, a world which *ex hypothesi* exemplifies the one can never justify us in inferring the other. Spencer appeals alternately to the "instability of the homogeneous" and the impossibility of complete equilibration to keep up the cosmic see-saw, but he can do so only by confining himself to a *part* of the universe. A world *wholly* homogeneous or equilibrated could no longer change, while so long as a part only is in process, the process cannot be represented as universal. Again, an infinite world cannot be *wholly* engaged either in evolution or in dissolution, so that it is really unmeaning to discuss the universality of the cosmic process until it is settled that we have a universe at all, capable of being considered as a whole. In the last resort, therefore, Spencer fails to deduce philosophically not only the necessity of progress, but also its compatibility with the evolution-dissolution oscillation, and even the general possibility of conceiving the world as a process. In other words, in spite of his intentions he does not succeed in giving a metaphysic of evolutionism.

In the *Principles of Biology* the most notable points are the definition of life as the continuous adjustment of internal to external relations, and the consequent emphasis on the need of adapting the organism to its environment. This exaggerates the passivity of life, and does not sufficiently recognize that the higher organisms largely adjust external to internal relations and adapt their environment to their needs. His universal process of Evolution seems to give Spencer a criterion of "higher" and "lower" "progression" and "degeneration," independent of the accidents of actual history, and unattainable by strictly Darwinian methods. The higher (at least in times of "evolution") is the more complex and differentiated, whether it invariably survives or not. On the other hand, he advances too easily from the maxim that function is prior to, and makes, structure to the conclusion that the results of use and disuse are therefore immediately incarnated in structural adaptations capable of hereditary transmission. This inference has involved him in much controversy with the ultra-Darwinians of Weismann's school, who deny the possibility of the inheritance of acquired characteristics altogether. And though Spencer's general position—that it is absurd to suppose that organisms after being modified by their life should give birth to offspring showing no traces of such modifications—seems the more philosophic, yet it does not dispose of the facts which go to show that most of the evidence for the direct transmission of adaptations is illusory, and that beings are organised to minimize the effects of life on the reproductive tissues, so that the transmission of the effects of use and disuse, if it occurs, must be both difficult and rare—far more so than is convenient for Spencer's psychology.

In his *Principles of Psychology* Spencer advocates the genetic explanation of the phenomena of the adult human mind by reference to its infant and animal ancestry. On the fundamental question, however, of the psychophysical connexion and the derivation of mind from matter, his utterances are neither clear nor consistent. On the one hand, his whole formulation of Evolution in mechanical terms urges him in the direction of materialism, and he attempts to compose the mind out of homogeneous units of consciousness (or "feeling") "similar in nature to those which we know as nervous shocks; each of which is the correlative of a rhythmical motion of a material unit or group of such units" (§ 62). On the other hand, when pressed by his disciple, Fiske (*Outlines of Cosmic Philosophy* ii. p. 444), he is ready to amend *nervous* into *psychical* shocks, which is no doubt what he ought to have meant but could not say without ruining the illusory bridge between the psychical and the physiological which is suggested in the phrase "nervous shock." And he admits (§ 63) that if we were compelled to choose between translating mental phenomena into physical and its converse, the latter would be preferable, seeing that the ideas of matter and motion, merely symbolic of unknowable realities, are complex states of consciousness built out of units of feeling. But easiest of all is it to leave the relation of the unknowable "substance of Mind" to the unknowable "substance of Matter" (substance he throughout conceives as the unknowable substrate of phenomena) to the Unknowable, as he finally does. To the theory of knowledge Spencer contributes a "transfigured realism," to mediate between realism and idealism, and the doctrine that "necessary truths," acquired in experience and congenitally transmitted, are a priori to the individual, though a posteriori to the race, to mediate between empiricism and apriorism. It has already been explained, however, that the biological foundations of the latter doctrine are questionable.

In the *Principles of Sociology* Spencer's most influential ideas have been that of the social organism, of the origination of religion out of the worship of ancestral ghosts, of the natural antagonism between nutrition and reproduction, industrialism and warfare. Politically, Spencer is an individualist of an extreme *laissez faire* type, and it is in his political attitude that the consequences of his pre-Darwinian conception of Evolution are most manifest. But for this he would hardly have established so absolute an antithesis between industrial and military competition, and have shown himself readier to recognize that the law of the struggle for existence, just because it is universal and equally (though differently) operative in every form of society, cannot be appealed to for guidance in deciding between the respective merits of an industrial or military and of an individualist or socialist organization of society.

In the *Principles of Ethics* Spencer, though relying mainly on the objective order of nature and the intrinsic consequences of actions for the guidance of conduct, conceives the ethical end in a manner intermediate between the hedonist and the evolutionist. The transition from the evolutionist criterion of survival—which in itself it is difficult to regard as anything but non-moral—to the criterion of happiness is effected by means of the psychological argument that pleasure promotes function and that living beings must, upon pain of extinction, sooner or later take pleasure in actions which are conducive to their survival. Hence pleasure is, on the whole, good, and asceticism reprehensible, although in man's case there has arisen (owing to the rapidity of evolution) a certain derangement and divergence between the pleasant and the salutary (§ 39). Nevertheless pleasure forms an "inexpugnable element" of the moral aim (§ 16). Conduct being the adjustment of acts to ends, and good conduct that which is conducive to the preservation of a pleasurable life in a society so adjusted that each attains his happiness without impeding that of others, life can be considered valuable only if it conduces to happiness. On the other hand, life must in the long run so conduce, whatever its present value may appear to be, because a constant process of adjustment is going on which is bound sooner or later to lead to a complete adjustment which will be perfect happiness. This is the refutation of pessimism, which ultimately agrees with optimism in making pleasure the standard of value. In this reasoning Spencer appears to have overlooked the possibility of an expansion of the ethical environment. If this is as rapid as (or more rapid than) the rate of adaptation, there will be no actual growth of adaptation and so no moral progress. Complete adaptation to an infinitely receding ideal is impossible, and relative adaptation depends on the distance between the actual and the ideal. Spencer, however, considers that he can not only anticipate such a state of complete adjustment, but even lay down the rules obtaining in it, which will constitute the code of "Absolute Ethics" and the standard for discerning the "least wrong" actions of relative ethics. He conceives it as a state of social harmony so complete that in it even the antagonism between altruism and egoism will have been overcome. Both of these are original and indispensable, but egoism has the priority, since there must be egoistic pleasure somewhere before there can be altruistic sympathy with it. And so in the ideal state everyone will derive egoistic pleasure from doing such altruistic acts as may still be needed. In it, too, the sense of duty will have become otiose and have disappeared, being essentially a relic of the history of the moral consciousness. Originally the socially salutary action was in the main that which was enjoined on the individual by his political and religious superiors and by social sentiment; it was also in the main that to which his higher, more complex and re-representative feelings prompted. Hence the fear with which the political, religious and social controls were regarded came to be associated also with the specifically moral control of lower by higher feelings, and engendered the coercive element in the feeling of obligation. Its authoritativeness depends on the intrinsic salutariness of self-control, and must cease to be felt as the resistance of the lower feelings relaxes. Hence Spencer concludes that the sense of duty is transitory and must diminish as moralization increases. In the preface to the last part of his *Ethics* (1893) Spencer regrets that "the Doctrine of Evolution has not furnished guidance to the extent he had hoped," but his contributions to ethics are not unlikely to be the most permanently valuable part of his philosophy.

After completing his system (1896) Spencer continued to revise it, and brought out new editions of the *Biology* (1898–1899) and *First Principles* (1900). The dates of his chief works are as follows: 1842, Letters to the *Nonconformist*, "*The Proper Sphere of Government.*" 1850, *Social Statics.* 1852, *The Theory of Population* (cf. part vi. of *Biology*); "The Development Hypothesis" (in *Essays*, vol. i.) 1853. *The Universal Postulate* (cf. *Psychology*, part vii.). 1854, "the Genesis of Science" (in *Essays*, vol. ii.). 1855, *Principles of Psychology* (1 vol.). 1857, *Progress, its Law and Cause* (*Essays*, vol. i.). 1858, *Essays* (containing most of his contributions to the *Westminster Review*; 1863, vol. ii.; 1885, vol. iii.). 1861, *Education: Intellectual, Moral, Physical.* 1862, *First Principles* (2nd ed., 1867; 6th, 1900). 1864–1867, *Principles of Biology* (2 vols.). 1872, *Principles of Psychology* (2nd ed., in 2 vols.). 1873, *The Study of Sociology.* 1876, vol. i., *The Principles of Sociology*; vol. ii., *Ceremonial Institutions*, 1879, *Political Institutions*, 1882; vol. iii., *Ecclesiastical Institutions*, 1885, completed 1896. 1879, *The Data of Ethics* (part i. of *Principles of Ethics* in 2 vols.; part iv., *Justice*, 1891; parts ii. and iii., *Inductions of Ethics* and *Ethics of Individual Life*, 1892; parts v. and vi., *Negative and Positive Beneficence*, 1893). 1884, *Man versus the State.* 1886, *Factors of Organic Evolution.* 1893, *Inadequacy of Natural Selection.* 1894, *A Rejoinder to Professor Weismann* and *Weismannism once more.* 1897, *Fragments.* 1902, *Facts and Comments.* 'An *Autobiography* in 2 vols. appeared posthumously in 1904. For a full bibliography of his works see W. H. Hudson's *Introduction to the Philosophy of Herbert Spencer* (up to 1895); and for a useful summary of his chief doctrines by Spencer himself, his preface to Collins's *Epitome of the Synthetic Philosophy.* He also supervised the compilation of a comprehensive series of volumes by various writers on *Descriptive Sociology*, of which by 1881 eight parts on different racial areas had been published (at a loss to him of £3250) as the result of fourteen years of labour. He then suspended this undertaking, but resolved that at his death it should be continued at the cost of his estate. In his will he appointed trustees, who were to entrust the supervision to Mr. H. R. Tedder, librarian of the Athenaeum Club; and the work was resumed accordingly after his death, five more parts being arranged for, one of which was published in 1910.

(F. C. S. S.)

SPENCER, JOHN CHARLES SPENCER, 3RD EARL (1782–1845), English statesman, better known by the courtesy title of Lord Althorp, which he bore during his father's lifetime, was the son of George John, 2nd Earl (1758–1834), grandson of John (1734–1783), created 1st Earl Spencer in 1765, and great-grandson of Charles Spencer, 3rd Earl of Sunderland. His father served in the ministries of Pitt, Fox and Grenville, and was first lord of the admiralty from 1794–1801; and his interest in literature was shown in his attention to the Althorp library, inherited from the 3rd Earl of Sunderland, which he developed into the finest private library in Europe; his wife, the eldest daughter of the 1st Earl Lucan, was conspicuous in London society for her gaiety and brightness. Their eldest son, John Charles, was born at Spencer House, London, on the 30th of May 1782. In 1800 he took up his residence at Trinity College, Cambridge, and for some time applied himself energetically to mathematical studies; but he spent most of his time in hunting and racing. Almost immediately after taking his degree in 1802, he set out on a continental tour, which was cut short, after he had passed some months in the chief cities in Italy, by the renewal of war. Through the influence of Pitt's government he was returned to parliament for the borough of Okehampton in Devonshire in April 1804, and, although he vacated his seat in February 1806, to contest the university of Cambridge against Lord Henry Petty and Lord Palmerston (when he was hopelessly beaten), he was elected in the same month for St Albans, and appointed a lord of the treasury. At the general election in November 1806, he was elected for Northamptonshire, and he continued to sit for the county until he succeeded to the peerage. His tastes were then, as ever, for country life, but his indignation at the duke of York's conduct at the Horse Guards led him to move a resolution of the House of Commons in 1809 for the duke's removal from his post. For the next few years after this speech Lord Althorp occasionally spoke in debate and always on the side of Liberalism, but from 1813 to 1818 he was only rarely in the House of Commons. His absence was partly due to a feeling that it was hopeless to struggle against the will of the Tory ministry, but more particularly to his marriage on the 14th of April 1814, to Esther, only daughter of Richard Acklom of Wiseton Hall, Northamptonshire, who died in childbirth 1818. In 1819, on his return to political life after her death, and for many years after that date he pressed upon the attention of the house the necessity of establishing a more efficient bankruptcy court, and of expediting the recovery of small debts; and he saw both these reforms accomplished before 1825. During the greater part of the reign of George IV. the Whigs lost their legitimate influence in the state from their want of cohesion, but this defect was soon remedied in 1830 when Lord Althorp was chosen their leader in the lower house, and his capacity for the position was proved by experience. When Lord Grey's administration was formed at the close of the year the chancellorship of the exchequer combined with the leadership of the House of Commons was entrusted to Lord Althorp, and to him more than to any other man, with the exception of the prime minister and the lord chancellor, may be attributed the success of the government measures. The budget, it is true, was a failure, but this misfortune was soon forgotten in the struggles over the Reform Bill. The consideration of the preliminaries of this measure was assigned to four ministers, two in the cabinet and two outside that body; but their proposals were, after careful examination, approved or rejected by Lord Grey and Lord Althorp before they were brought under the notice of the cabinet. When the Bill was ready for introduction to the House of Commons its principles were expounded by Lord John Russell; but from the commencement of the protracted discussion over its details he had the assistance of Lord Althorp, and after some weeks of incessant toil, which the physique of Lord John Russell could not sustain any longer, the whole responsibility was cast on Lord Althorp. To combat the objections of three such pertinacious opponents as Croker, Sugden and Wetherell required both skill and courage, and in Lord Althorp these qualities were found. On one evening he made as many as twenty speeches. The Reform Bill was carried at last, and popular instinct was right in assigning to the leader of the house a credit only second to that earned by Lord John Russell. After the dissolution of 1833 the Whigs returned to power with augmented numbers; but differences soon showed themselves among both leaders and followers, and their majority crumbled away. Their position was strengthened for a time by triumphantly carrying a new poor law bill; and even their keenest critics would not allow that, had the Whig propositions on tithes and church rates been carried into effect, many years of passionate controversy would have been spared. The ministry of Lord Grey was shattered to pieces by difficulties over an Irish coercion bill. Although Lord Melbourne became premier (July 14, 1834), the fortunes of the ministry rested on Lord Althorp's presence in the House of Commons.

The death of the 2nd Earl Spencer in November 1834, called his son to the upper house, and William IV. took advantage of this event to summon a Tory cabinet to his side. The new Lord Spencer abandoned the cares of office and returned to country life with unalloyed delight. Henceforth agriculture, not politics, was his principal interest. He was the first president of the Royal Agricultural Society (founded 1838), and a notable cattle-breeder. Often as he was urged by his political friends to come to their assistance, he rarely quitted the peaceful pleasures which he loved. He died at Wiseton on the 1st of October 1845, being succeeded as 4th Earl, in default of issue, by his brother Frederick (d. 1857). He had held, as a statesman, a remarkable position. The Whigs required, to carry the Reform Bill, a leader of unstained character, one to whom party spirit could not attach the suspicion of greed of office, and against Lord Althorp malevolence was powerless. No stronger proof of his pre-eminence could be given than the oft-quoted saying of Lord Hardinge that one of Croker's ablest speeches was demolished by the simple statement of Lord Althorp that he had collected some figures which entirely refuted it, but had lost them. The trust which the house put in him then was never wanting.

SPENCER, JOHN POYNTZ SPENCER, 5th Earl (1835–1910), English statesman, was the son of the 4th Earl and his first wife, a daughter of William Stephen Poyntz, of Cowdray Park, Sussex. Born on the 27th of October 1835, and educated at Harrow and Trinity College, Cambridge, he was a member of parliament for a few months before he succeeded to the earldom in December 1857. His long career as a Liberal politician dates from his acceptance of the office of lord-lieutenant of Ireland under Gladstone in 1868, a post which he retained until 1874. When the Liberals returned to power in 1880 he was appointed lord president of the council, but in 1882 he entered upon a second term of office as lord-lieutenant of Ireland. The three years during which Earl Spencer now filled this position was a period of exceptional disorder in Ireland, marked by a long series of outrages and conspiracies associated with the "Invincibles," but the courage and firmness which he then displayed won the admiration of all, and made his adoption of the policy of Home Rule in 1885 an event of considerable interest. In the short Liberal administration of 1886 he was lord-president of the council, and from 1892 to 1895 he was a very capable first lord of the admiralty; it is on record that Gladstone, on retiring in 1904, would have recommended the Queen, if she had consulted him, to summon Lord Spencer to the premiership. From 1902 to 1905 he was the Liberal leader in the House of Lords, and early in 1905, when a change of government was seen to be probable, it was thought in some quarters that he would be the most suitable Liberal prime minister. But his health broke down just at this time, and he took no further part in political life, although he survived until the 13th of August 1910, when he died at Althorp. For forty-five years the earl was a Knight of the Garter; he was lord-lieutenant of Northamptonshire for upwards of thirty years, and he had a reputation as a keen and daring rider to hounds. The fine library, collected at Althorp by the 2nd earl, was sold by him for £250,000 to Mrs Rylands, the widow of a Manchester merchant, and was by her presented to the city of Manchester.

Earl Spencer had no children, and his successor was his half-brother, Charles Robert Spencer (b. 1857), who became the 6th earl. As the Hon. Charles R. Spencer he was one of the parliamentary representatives for Northamptonshire from 1880 to 1895 and again from 1900 to 1905, and was vice-chamberlain of the royal household from 1892 to 1895. In 1905 he was appointed lord chamberlain, and in the same year he was raised to the peerage as Viscount Althorp.

SPENCER, WILLIAM ROBERT (1769–1834), English poet and wit, was the son of Lord Charles Spencer, second son of Charles Spencer, 3rd duke of Marlborough and 5th earl of Sunderland. He was educated at Harrow and Christ Church, Oxford, but left the university without taking a degree. Spencer's wit made him a popular member of society, but he took no part in public life although he numbered among his friends leading statesmen like Pitt, Fox and Sheridan. He was an accomplished writer of "occasional" verse, which was warmly praised by Scott, by Christopher North and by Byron, who placed him in the same rank as Moore, Rogers and Campbell. In 1796 he published an English version of Bürger's *Leonore*, and in 1802 he burlesqued German romance in his *Urania*, which was produced on the stage at Drury Lane. Among his best-known pieces, which were published in a collection of his poems in 1811, were "Beth Gelert" and "Too Late I Stayed." He died in poverty in Paris in 1834. In 1791 he married Susan, daughter of Count Jenison-Walworth, chamberlain to the elector palatine, by whom he had five sons and two daughters. One son, Aubrey George Spencer (1795–1872), became first bishop of Newfoundland in 1839, being afterwards translated to the See of Jamaica. Another son, George Trevor Spencer (1799–1866), was in 1837 consecrated second bishop of Madras. He published several books relating to missionary work in India; on his return to England in 1849 he was appointed assistant to the bishop of Bath and Wells, and in 1860 became chancellor of St Paul's Cathedral. He married, in 1823, Harriet, daughter of Sir Benjamin Hobhouse and sister of Lord Broughton.

See W. R. Spencer, *Poems* (London, 1835), containing a biographical memoir; *The Annual Register* (1834); *Alumni Oxonienses 1715–1886*, annotated by J. Foster (4 vols., Oxford, 1891).

SPENCER, a township of Worcester county, Massachusetts, U.S.A., about 11 m. W. of Worcester. Pop. (1890), 8747; (1900), 7627, of whom 1614 were foreign-born; (1910, U.S. census), 6740. Area, about 34·1 sq. m. The township is served by the Boston & Albany railway and by inter-urban electric lines. The Richard Sugden Public Library, founded in 1889, had 12,000 volumes in 1908. Bemis Memorial Park and the Samuel Bemis Monument were dedicated in 1901 in honour of the first settler of Spencer. There are three other public parks. Among the township's manufactures are boots and shoes, woollens, muslin underwear, wire, and wooden and paper boxes. Spencer was a part of the Leicester grant; was first settled in 1721; was the "West Parish of Leicester" in 1744–1753; and in 1753 was incorporated as a township, under its present name. In one house in Spencer were born Elias Howe, jun., the inventor of the sewing-machine, and his uncles, William Howe, inventor of the "Howe truss" bridge (see Bridges), and Tyler Howe (1800–1880), inventor (in 1855) of the spring bed; in 1909 a memorial was dedicated to these three inventors.

See Henry M. Tower, *Historical Sketches Relating to Spencer, Mass.* (4 vols., Spencer, 1901–1909).

SPENER, PHILIPP JAKOB (1635–1705), German theologian, was born on the 13th of January 1635, at Rappoltsweiler in Upper Alsace. After a brief stay in the grammar school of Colmar he went to Strassburg in 1651, where he devoted himself to the study of philology, history and philosophy, and won his degree of master (1653) by a disputation against the philosophy of Hobbes. He then became private tutor to the princes Christian and Charles of the Palatinate, and lectured in the university on philology and history. From 1659 to 1662 he visited the universities of Basel, Tübingen and Geneva, and commenced the study of heraldry, which he pursued throughout his life. In Geneva especially his religious views and tendencies were turned in the direction of mysticism. He returned to Strassburg in 1663, where he was appointed preacher without pastoral duties, with the right of holding lectures. Three years afterwards he was invited to become the chief pastor in the Lutheran Church at Frankfort-on-Main. Here he published his two chief works, *Pia desideria* (1675) and *Allgemeine Gottesgelehrtheit* (1680), and began that form of pastoral work which resulted in the movement called *Pietism*. In 1686 he accepted the invitation to the first court chaplaincy at Dresden. But the elector John George III., at whose personal desire the post had been offered to him, was soon offended at the fearless conscientiousness with which his chaplain sought to discharge his pastoral duties. Spener refused to resign his post, and the Saxon government hesitated to dismiss him. But in 1691 the Saxon representative at Berlin induced the court of Brandenburg to offer him the rectorship of St Nicholas in Berlin with the title of "Konsistorialrat." In Berlin Spener was held in high honour, though the tendencies of the court and the government officials were rather rationalistic than pietistic. The university of Halle was founded under his influence in 1694. All his life long Spener had been exposed to the attacks and abuse of the orthodox Lutheran theologians; with his years his opponents multiplied, and the movement which he had inaugurated presented increasingly matter for hostile criticism. In 1695 the theological faculty of Wittenberg formally laid to his charge 264 errors, and only his death on the 5th of February, 1705, released him from these fierce conflicts. His last important work was *Theologische Bedenken* (4 vols., 1700–1702), to which was added after his death *Letzte theologische Bedenken*, with a biography of Spener by C. H. von Canstein (1711).

Though Spener has been justly called "the father of Pietism," hardly any of the errors and none of the extravagances of the movement can be ascribed to him personally. So far was he from sharing them that A. Ritschl (*Geschichte des Pietismus*, ii. 163) maintains that "he was himself not a Pietist," as he did not advocate the quietistic, legalistic and semi-separatist practices of Pietism, though they were more or less involved in the positions he assumed or the practices which he encouraged or connived at. The only two points on which he departed from the orthodox Lutheran faith of his day were the requirement of regeneration as the *sine qua non* of the true theologian, and the expectation of the conversion of the Jews and the fall of Papacy as the prelude of the triumph of the church. He did not, like the later Pietists, insist on the necessity of a conscious crisis of conversion, nor did he encourage a complete breach between the Christian and the secular life.

Spener was a voluminous writer. The list of his published works comprises 7 vols. folio, 63 quarto, 7 octavo, 46 duodecimo; a new edition of his chief writings was published by P. Grünberg in 1889. See W. Hossbach, *Philipp Jakob Spener und seine Zeit* (1828, 3rd ed., 1861); A. Ritschl, *Geschichte des Pietismus*, ii. (1884); E. Sachsse, *Ursprung und Wesen des Pietismus* (1884); P. Grünberg, *P. J. Spener* (3 vols., 1893–1906).

SPENNYMOOR, a market town in the Bishop Auckland parliamentary division of Durham, England, 6 m. S. of the city of Durham, on a branch of the North Eastern railway. Pop of urban district, which includes several neighbouring parishes (1901), 16,665. It is in the midst of a populous coal-mining district, and its growth is modern.

SPENS, THOMAS DE (*c.* 1415–1480), Scottish statesman and prelate, received his education at Edinburgh, and by his exceptional abilities attracted the notice of the advisers of the Scottish king, James II., who sent him on errands to England and to France. About 1450 he became bishop of Galloway; soon afterwards he was made keeper of the privy seal, and in 1459 he was chosen bishop of Aberdeen. Much of his time, however, was passed in journeys to France and to England, and in 1464 he and Alexander Stewart, duke of Albany, a son of James II., were captured at sea by some English sailors. Edward IV., to whom the bishop had previously revealed an assassination plot, set him at liberty, and he was partly responsible for the treaty of peace made about this time between the English king and James III. He also helped to bring about the meeting between Edward IV. and Louis XI. of France at Picquicny, and another treaty of peace between England and Scotland in 1474. Spens was a frequent attender at the Scottish parliaments, and contributed very generously to the decoration of his cathedral at Aberdeen. He died in Edinburgh on the 14th of April 1480.

SPENSER, EDMUND (*c.* 1552–1599), English poet, author of the *Faery Queen*, was born in London about the year 1552. The received date of his birth rests on a passage in sonnet lx. of the *Amoretti*. He speaks there of having lived forty-one years; the *Amoretti* was published in 1595, and described on the title-page as "written not long since"; this would make the year of his birth 1552 or 1553. We know from the *Prothalamion* that London was his birthplace. This at least seems the most natural interpretation of the words—

> "Merry London, my most kindly nurse,
> That to me gave this life's first native source."

In the same poem he speaks of himself as taking his name from "an house of ancient fame." Several of his pieces are addressed to the daughters of Sir John Spencer, head of the Althorp family; and in *Colin Clout's Come Home Again* he describes three of the ladies as—

> "The honour of the noble family
> Of which I meanest boast myself to be."

Mr R. B. Knowles, however, is of the opinion (see the *Spending of the Money of Robert Nowell*, privately printed, 1877) that the poet's kinsmen must be sought among the humbler Spencers of north-east Lancashire. Robert Nowell, a London citizen, left a sum of money to be distributed in various charities, and in the account-books of his executors among the names of other beneficiaries has been discovered that of "Edmund Spensore, scholar of the Merchant Taylor School, at his going to Pembroke Hall in Cambridge." The date of this benefaction is the 28th of April 1569. As the poet is known to have been a sizar of Pembroke, the identification is beyond dispute. Till this discovery it was not known where Spenser received his school education. The speculations as to the poet's parentage, started by the Nowell MS., are naturally more uncertain. Mr Knowles found three Spensers in the books of the Merchant Taylors, and concluded that the poorest of them, John Spenser, a "free journeyman" in the "art or mystery of clothmaking," might have been the poet's father, but he afterwards abandoned this theory. Dr Grosart, however, adhered to it, and it is now pretty generally accepted. The connexion of Spenser with Lancashire is also supported by the Nowell MS.—several Spensers of that county appear among the "poor kinsfolk" who profited by Nowell's bounty. The name of the poet's mother was Elisabeth, and he notes as a happy coincidence that it was borne by the three women of most consequence to him—wife, queen and mother (*Amoretti, lxxiv.*).

It is natural that a poet so steeped in poetry as Spenser should show his faculty at a very early age; and there is strong reason to believe that verses from his pen were published just as he left school at the age of sixteen or seventeen. Certain pieces, translations from Du Bellay and Petrarch, afterwards included in a volume of poems by Spenser published in 1591, are found in a miscellany, *Theatre for Worldings*, issued by a Flemish Protestant refugee, John van der Noodt, on the 25th of May 1569. The translations from Du Bellay appear in blank verse in the miscellany, and are rhymed in sonnet form in the later publication, but the diction is substantially the same; the translations from Petrarch are republished with slight variations. Poets were so careless of their rights in those days and publishers took such liberties that we cannot draw for certain the conclusion that would be inevitable if the facts were of more modern date; but the probabilities are that these passages in Van der Noodt's *Theatre*, although the editor makes no acknowledgment, were contributed by the schoolboy Spenser.[1] As the exercises of a schoolboy writing before our poetic diction was enriched by the great Elizabethans, they are remarkable for a sustained command of expression which many schoolboys might exhibit in translation now, but which was a rarer and more significant accomplishment when Surrey and Sackville were the highest models in post-Chaucerian English.

Little is known of Spenser's Cambridge career, except that he was a sizar of Pembroke Hall, took his bachelor's degree in 1572, his master's in 1576, and left Cambridge without having obtained a fellowship. Dr Grosart's inquiries have elicited the fact that his health was not good—college allowances while he was in residence being often paid "Spenser aegrotanti." One of the fellows of Pembroke strongly influenced his destiny. This was Gabriel Harvey, a prominent figure in the university life of the time, an enthusiastic educationist, vigorous, versatile, not a little vain of his own culture and literary powers, which had gained him a certain standing in London society. The revival and advancement of English literature was a passion of the time, and Harvey was fully possessed by it. His fancy for reforming English verse by discarding rhyme and substituting unrhymed classical metres, and the tone of his controversy with Thomas Nash, have caused him to be regarded as merely an obstreperous and pragmatic pedant; but it is clear that Spenser, who had sense enough not to be led astray by his eccentricities, received active and generous help from him and probably not a little literary stimulus. Harvey's letters to Spenser[2] throw a very kindly light on his character. During his residence at the university the poet acquired a knowledge of Greek, and at a later period offered to impart that language to a friend in Ireland (see Ludowick Bryskett, *Discourse of Civil Life*, London, 1606—written twenty years previously). Spenser's affinity with Plato is most marked, and he probably read him in the original.

Three years after leaving Cambridge, in 1579, Spenser issued his first volume of poetry, the *Shepherd's Calendar*. Where and how he spent the interval have formed subjects for elaborate speculation. That most of it was spent in the study of his art we may take for granted. That he lived for a time in the "north parts" of England; that there or elsewhere he fell in love with a lady whom he celebrates under the anagram of "Rosalind," and who was most likely Rose, a daughter of a yeoman named Dyneley, near Clitheroe; that his friend Harvey urged him to return south, and introduced him to Sir Philip Sidney; that Sidney took to him, discussed poetry with him, introduced him at court, put him in the way of preferment—are ascertained facts in his personal history. Dr Grosart conjectures with considerable plausibility that he was in Ireland in 1577. The words "for long time far estranged" in E.K.'s preface to the *Shepherd's Calendar* point that way. Spenser undoubtedly entered the service of the earl of Leicester either in 1578 or a year earlier (*Carew Papers*).

The interest of the *Shepherd's Calendar* is mainly personal to Spenser. Its twelve poems continue to be read chiefly because they were the first published essays of the author of the *Faery Queen*, the poems in which he tried and disciplined his powers. They mark no stage in the history of pastoral poetry. The title, borrowed from a French almanack of the year 1496, which was translated into English in 1503 and frequently reprinted, is attractive but hardly tallies with the subject. It may have been an afterthought. Spenser had too strong a genius not to make his own individuality felt in any form that he attempted, and his buoyant dexterity in handling various schemes of verse must always afford delight to the connoisseur in such things. But a reader not already interested in Spenser, or not already familiar with the artificial eclogue, would find little to attract him in the *Shepherd's Calendar*. The poems need a special education; given this, they are felt to be full of charm and power, a fresh and vivid spring to the splendid summer of the *Faery Queen*. The diction is a studiously archaic artificial compound, partly Chaucerian, partly North Anglian, partly factitious; and the pastoral scenery is such as may be found in any country where there are sheep, hills, trees, shrubs, toadstools and running streams. That Spenser, having been in the north of England, should have introduced here and there a touch of north country colour is natural enough, but it is not sufficient to give a character to the poems as pastoral poems. As such they follow continuously and do not violently break away from Latin, Italian and French predecessors, and Professor George Saintsbury is undoubtedly right in indicating Marot as the most immediate model. At the same time one can quite understand on historical grounds why the *Shepherd's Calendar* was hailed with enthusiasm as the advent of a "new poet." Not only was it a complete work in a form then new to English literature, but the execution showed the hand of a master. There had been nothing so finished, so sustained, so masterful in grasp, so brilliant in metre and phrase, since Chaucer. It was felt at once that the poet for whom the age had been waiting had come. The little coterie of friends whose admiration the young poet had won in private were evidently concerned lest the wider public should be bewildered and repelled by the unfamiliar pastoral form and rustic diction. To put the public at the right point of view the poems were published with a commentary by "E.K."—supposed to be one Edward Kirke, who was an undergraduate with Spenser at Pembroke. This so-called "glosse" explained the archaic words, revealed the poet's intentions, and boasted that, as in the case of Virgil, the pastoral poetry of the "new poet" was but "a proving of the wings for higher and wider flights." The "new poet's" name was withheld; and the identification of the various "shepherds"—of Cuddie and Roffy and Diggon Davie, and the beauteous golden-haired "widow's daughter of the glen"—was fortunately reserved to yield delight to the ingenious curiosity of a later age.[3] On the subject of Spenser's obligations the "glosse" is very misleading. An eclogue drawn almost entirely from Virgil is represented as jointly inspired by Virgil and Theocritus and chiefly by the latter. Marot is belittled and his claim to be a poet called in question. As regards the twelfth eclogue suggested by and in part translated from his poetry, his influence is ignored. The stanzas Professor Hales cites as autobiographical are actually taken from Marot's eclogue, *Au Roi sous les noms de Pan et Robin*. Dr Grosart falls into the same error.

The *Shepherd's Calendar* was published at Gabriel Harvey's instance, and was dedicated to Sir Philip Sidney. It was one out of many poetical schemes on which the young poet was busy in the flush of conscious power and high hopes excited by the admiration of the literary authorities whose approval was then most to be coveted. His letters to Harvey and Harvey's letters to him furnish hints for a very engaging fancy picture of Spenser at this stage of his life—looking at the world through rose-coloured spectacles, high in favour with Sidney and Leicester, dating his letters from Leicester House, gaily and energetically discussing the technicalities of his art, with some provision from his powerful friends—certain, but the form of it delightfully uncertain—going to court in the train of Leicester, growing pointed beard and mustachios of fashionable shape, and frightening his ever-vigilant friend and mentor Harvey by the light courtier-like tone of his references to women. The studious pastoral poet from "north parts" had blossomed with surprising rapidity in the image of the gay fortune-seeking adventurers who crowded the court of the virgin queen in those stirring times. Some of the poems which he mentions to Harvey as then completed or on the anvil—his *Dreams*, his *Nine Comedies*, his *Dying Pelican* and his *Stemmata dudleiana* (singing the praises of the noble family which was befriending him)—have not been preserved, at least in any form that can be certainly identified. Among the lost works was his *English Poet*—a contribution to literary criticism. He had sent Harvey a portion of the *Faery Queen*, which he was eager to continue; but Harvey did not think much of it—a judgment for which Harvey is often ridiculed as a dull pedant, as if we knew for certain that what was submitted to him was identical with what was published ten years later.

Spenser was appointed secretary to the lord-deputy of Ireland in 1580, and was one of the band of adventurers who, with mixed motives of love of excitement, patriotism, piety and hopes of forfeited estates, accompanied Lord Arthur Grey of Wilton to Ireland to aid in the suppression of Desmond's rebellion. Regret is sometimes expressed that the author of the *Faery Queen*, who ought to have been dreamy, meditative, gentle and refined, should have been found in such company, and should have taken part in the violent and bloody scenes of Lord Grey's two years' attempt at "pacification." But such things must be judged with reference to the circumstances and the spirit of the time, and it must be remembered that England was then

[1] The first versions of the *Visions* of Petrarch and Du Bellay are reproduced by Dr Grosart in his *Complete Works of Spenser*, vol. iv. (London, 1882). The translations of Petrarch are imitated from Marot. Koeppel (*Englische Studien*, vol. xv.), questions whether they are by Spenser (see also J. B. Fletcher, *Modern Language Notes*, vol. xxii.).

[2] *Letter-Book of Gabriel Harvey* (Camden Society).

[3] See Dr Grosart's *Complete Works of Spenser*, vol. i.

engaged in a fierce struggle for existence against the Catholic powers of the Continent. Of Lord Grey's character his secretary was an enthusiastic admirer, exhibiting him in the *Faery Queen* as Arthegal, the personification of justice; and we know exactly what were his own views of Irish policy, and how strongly he deplored that Lord Grey was not permitted to carry them out. Spenser's *View of the State of Ireland* drawn up after fourteen years' experience, but first printed in 1633 by Sir James Ware, who complains of Spenser's harshness and inadequate knowledge (*History of Ireland*, appendix), is not the work of a gentle dreamer, but of an energetic and shrewd public official.

The *View* is not a descriptive work; there is nothing in the style to indicate that it was written by a poet; it is an elaborate state paper, the exposition in the form of a dialogue of a minutely considered plan for the pacification of Ireland, written out of zeal for the public service for the eyes of the government of the day. A very thoroughgoing plan it is. After passing in review the history and character of the Irish, their laws, customs, religion, habits of life, armour, dress, social institutions and finding "evil usages" in every department, he propounds his plan of "reformation." Reformation can be effected only by the sword, by the strong hand. The interlocutor in the dialogue holds up his hands in horror. Does he propose extermination? By no means; but he would give the Irish a choice between submission and extermination. The government had vacillated too long, and, fearing the cost of a thorough operation, had spent twice as much without in any way mending matters. Let them send into Ireland 10,000 foot and 1000 horse, disperse them in garrisons—a complete scheme of localities is submitted—give the Irish twenty days to come in; if they did not come in then, give no quarter afterwards, but hunt them down like wild beasts in the winter time when the covert is thin; "if they be well followed one winter, ye shall have little work to do with them the next summer"; famine would complete the work of the sword; and in eighteen months' time peace would be restored and the ground cleared for plantation by English colonists. There must be no flinching in the execution of this plan—"no remorse or drawing back for the sight of any such rueful object as must thereupon follow, nor for compassion of their calamities, seeing that by no other means it is possible to recover them, and that these are not of will but of very urgent necessity." The government had out of foolish compassion drawn back before when Lord Grey had brought the recalcitrant Irish to the necessary extremity of famine; the gentle poet warns them earnestly against a repetition of the blunder.

Such was Spenser's plan for the pacification of Ireland, propounded not on his own authority, but as having support in "the consultations and actions of very wise governors and counsellors whom he had sometimes heard treat thereof." He knew that it was "bloody and cruel"; but he contended passionately that it was necessary for the maintenance of English power and the Protestant religion. The method was repugnant to the kindly nature of average Englishmen; from the time of Lord Grey no English authority had the heart to go through with it till another remorseless zealot appeared in the person of Cromwell. That Cromwell knew the treatise of "the sage and serious Spenser," perhaps through Milton, is probable from the fact that the poet's Irish estates were secured to his grandson by the Protector's intervention in 1657. These estates had been granted to Spenser as his share in the redistribution of Munster—3000 acres of land and Kilcolman Castle, an ancient seat of the Desmonds, in the north of the county of Cork. The elaborate and business-like character of the *View* shows that the poet was no sinecurist, but received his reward for substantial political services. He ceased to be secretary to the lord-deputy when Lord Grey was recalled in 1582; but he continued in the public service, and in 1586 was promoted to the onerous position of clerk to the council of Munster.

Amidst all the distractions of his public life in Ireland Spenser kept up his interest in literature, and among proper subjects for reform included Irish poetry, of which he could judge only through the medium of translations. He allows it some merit—"sweet wit," "good invention," "some pretty flowers"—but laments that it is "abused to the gracing of wickedness and vice." Meanwhile he seems to have proceeded steadily with the composition of the *Faery Queen*, translating his varied experience of men and affairs into the picturesque forms of his allegory, and expressing through them his conception of the immutable principles that ought to regulate human conduct. He had, as we have seen, conceived a work of the kind and made a beginning before he left England. The conception must have been very much deepened and widened and in every way enriched by his intimate daily contact with the actual struggle of conflicting individuals and interests and policies in a great crisis. Some four or five years later, being asked in a mixed company of English officials in Ireland (as recorded in Lodowick Bryskett's *Discourse of Civil Life*) to give off-hand a short sketch of "the ethical part of moral philosophy" and the practical uses of the study, Spenser explained to these simple-minded men that the subject was too intricate for an impromptu exposition, but that he had in hand a work called the *Faery Queen* in which an ethical system would be exhibited in action. The respect paid by his official brethren to Spenser as a man, "not only perfect in the Greek tongue, but also very well read in philosophy, both moral and natural," is an interesting item in his biography. Some years later still, when Spenser was settled at Kilcolman Castle, Sir Walter Raleigh found him with three books of the *Faery Queen* completed, and urged him to come with them to London. London accordingly he revisited in 1589, after nine years' absence. There is a very pretty record of this visit in *Colin Clout's Come Home Again*, published in 1595, but written in 1591, immediately after his return to Kilcolman. The incidents of the visit, by that time matters of wistful memory, are imaged as a shepherd's excursion from his quiet pastoral life into the great world. Colin Clout calls round him once again the masked figures of the *Shepherd's Calendar*, and describes to them what he saw, how he fared, and whom he met at the court of Cynthia, and how, through the influence of "the Shepherd of the Ocean," he was admitted at timely hours to play on his oaten pipe in the great queen's presence.

How much is pure fiction and how much veiled fact in this picture cannot now be distinguished, but it is undoubted that Spenser, though his chief patrons Leicester and Sidney were now dead, was very graciously received by the great world on his return to London. Not only did the queen grant him an audience, but many ladies of the court, several of whom he afterwards honoured with dedications, honoured him with their patronage. The first three books of the *Faery Queen*, which were entered at Stationers' Hall on the 1st of December 1589, were published in 1590, and he was proclaimed at once with remarkable unanimity by all the writers of the time as the first of living poets.

From the first week of its publication the literary world has continued unanimous about the *Faery Queen*, except on minor points. When romanticism was at its lowest ebb Pope read Spenser in his old age with as much delight as in his boyhood. Spenser speaks himself of having had his detractors, of having suffered from the venomous tooth of the Blatant Beast, and he seems to have had in more than ordinary share the poet's sensitiveness to criticism; but the detraction or indifference have generally been found among men who, like the lord high treasurer Burghley, have no liking for poetry of any kind. The secret of Spenser's enduring popularity with poets and lovers of poetry lies specially in this, that he excels in the poet's peculiar gift, the instinct for verbal music. Shakespeare, or the author of the sonnet usually assigned to him, felt and expressed this when he drew the parallel between "music and sweet poetry"—

"Thou lovest to hear the sweet melodious sound
That Phoebus' lute, the queen of music, makes;
And I in deep delight am chiefly drowned
Whenas himself to singing he betakes."

This is an early word in criticism of Spenser, and it is the last word about his prime and unquestionable excellence—a word in which all critics must agree. Whether he had imagination in the highest degree or only luxuriant fancy, and whether he could tell a story in the highest epic manner or only put together a richly varied series of picturesque incidents, are disputable points; but about the enchantment of his verse there can be no difference of opinion. It matters not in the least that he gains his melody often by archaic affectations and licences of diction; there, however purchased, the marvellously rich music is. In judging of the structure of the *Faery Queen* we must always remember that, long and diffuse as it is, what we have is but a fragment of the poet's design, and that the narrative is regulated by an allegorical purpose; but, however intricate, however confused, the reader may feel the succession of incidents to be, when he studies the succession of incidents, it is only at the call of duty that he is likely to occupy himself with such a study in reading Spenser.

The ethical value of the allegory has been very variously estimated. The world would probably never have divined that there was any allegory if he had not himself drawn attention to it in a prose dedication and in doggerel headings to the cantos. It was apparently at his friend Raleigh's suggestion that the poet condescended to explain his ethical purpose in *A Letter of the Author's* addressed to Sir Walter and dated the 23rd of January 1589–1590; otherwise it would have been as problematical as the similar intention in the case of the *Idylls of the King* before that intention was expressly declared. It is almost to be regretted, as far as the allegory is concerned, that the friendly "E. K." was not employed to furnish a "glosse" to the *Faery Queen* as he had done to the *Shepherd's Calendar*. Undoubtedly the peculiar "poetic luxury" of the *Faery Queen* can be enjoyed without any reference to the allegory; even Professor Dowden, the most eloquent champion of Spenser's claims as a "teacher," admits that it is a mistake to look for minute correspondence between outward symbol and underlying sense, and that the poet is least enjoyable where he is most ingenious. Still the allegory governs the structure of the poem, and Spenser himself attached great importance to it as determining his position among poets. The ethical purpose is distinctive of the poem as a whole; it was foremost in Spenser's mind when he conceived the scheme of the poem, and present with him as he built up and articulated the skeleton; it was in this respect that he claimed to have "overpassed" his avowed models Ariosto and Tasso. If we wish to get an idea of Spenser's imaginative force and abundance, or to see his creations as he saw them, we must not neglect the allegory. It is obvious from all that he says of his own work that in his eyes the ethical meaning not only heightened the interest of the marvellously rich pageant of heroes and heroines, enchanters and monsters, but was the one thing that redeemed it from romantic commonplace. For the right appreciation of many of the characters and incidents a knowledge of the allegory is indispensable. For example, the slaughter of Error by the Red Cross knight would be merely disgusting but for its symbolic character; the iron Talus and his iron flail is a revolting and brutally cruel monster if he is not regarded as an image of the executioner of righteous law; the Blatant Beast, a purely grotesque and ridiculous monster to outward view, acquires a serious interest when he is known to be an impersonation of malignant detraction.

Notwithstanding its immense range, the *Faery Queen* is profoundly national and Elizabethan, containing many more or less cryptic allusions to contemporary persons and interests. It has never been popular abroad, as is proved by the fact that there is no complete translation of it in any of the Continental languages. This is doubtless on account of a certain monotony in the subject-matter, which is only partially relieved by subtle variations. The same objection applies to the famous "Spenserian stanza" (see below) with its concluding Alexandrine. It was by no means a happy invention, but its infelicity is disguised by its author's marvellous skill in rhythm, and thus recommended it was adopted by Byron and Keats. In his own day Spenser was criticized by Sidney, Ben Jonson, Daniel and others for the artificiality of his language, his "aged accents and untimely words," but Ben Jonson went further—"Spenser's stanza pleased him not, nor his matter." Milton, on the other hand, duly appreciated "our sage and serious poet," and he has been followed by a long line of distinguished judges. It was Charles Lamb who named Spenser "the poet's poet."

After the publication of the *Faery Queen* Spenser seems to have remained in London for more than a year, to enjoy his triumph. It might be supposed, from what he makes the Shepherd of the Ocean say in urging Colin Clout to quit his banishment in Ireland, that Raleigh had encouraged him to expect some permanent provision in London. If he had any such hopes, they were disappointed. The thrifty queen granted him a pension of £50, which was paid in February 1591, but nothing further was done for him. Colin Clout's explanation that the selfish scrambling and intriguing of court life were not suited to a lowly shepherd swain, and that he returned to country life with relief, may be pastoral convention, or it may have been an expression of the poet's real feelings on his return to Kilcolman, although as a matter of fact there seems to have been as much scrambling for good things in Munster as in London. Certain it is that he did return to Kilcolman in the course of the year 1591, having probably first arranged for the publication of *Daphnaida* and *Complaints*. *Daphnaida* is a pastoral elegy on the death of the niece of the mistress of the robes. The fact implied in the dedication that he was not personally known to the lady has more than once provoked the solemn remark that the poet's grief was assumed. Of course it was assumed; and it is hardly less obvious that sincerity of personal emotion, so far from being a merit in the artificial forms of pastoral poetry, the essence of which lies in its dreamy remoteness from real life, would be a blemish and a discord. Any suggestion of the poet's real personality breaks the charm; once raise the question of the poet's personal sincerity, and the pastoral poem may at once be thrown aside. The remark applies to all Spenser's minor poetry, including his love-sonnets; the reader who raises the question whether Spenser really loved his mistress may have a talent for disputation, but none for the full enjoyment of hyperbolical poetry. *Complaints*, also published in 1591, is a miscellaneous collection of poems written at different periods. The volume contained *The Ruins of Time*; *The Tears of the Muses*, *Virgil's Gnat*; *Mother Hubbard's Tale*; *The Ruins of Rome*; *Muiopotmos*; *Visions of the World's Vanity*; *Bellay's Visions*; *Petrarch's Visions*. Some of these pieces are translations already alluded to and interesting only as the exercises of one of our greatest masters of melodious verse; but two of them, *The Tears of the Muses* and *Mother Hubbard's Tales*, have greater intrinsic interest. The first is the complaint of the decay of learning alluded to in *Midsummer Night's Dream*, v. i. 52—

> "The thrice three Muses mourning for the death
> Of Learning late deceased in beggary."

The lament, at a time when the Elizabethan drama was "mewing its mighty youth," was not so happy as some of Spenser's political prophecies in his *View of Ireland*; but it is idle work to try to trace the undercurrents and personal allusions in such an occasional pamphlet. *Mother Hubbard's Tale*, a fable in Chaucerian couplets, shows a keenness of satiric force not to be paralleled in any other of Spenser's writings, and suggests that he left the court in a mood very different from Colin Clout's.

Spenser returned to London probably in 1595. He had married in the interval a lady whose Christian name was Elizabeth—Dr Grosart says Elizabeth Boyle. The marriage, celebrated on the 11th of June 1594, was followed by a rapid succession of publications. The first was a volume (entered at Stationers' Hall, on the 19th of November 1594; published 1595) containing the *Amoretti*, a series of exquisite sonnets commemorative of the moods and incidents of his courtship, and the magnificent *Epithalamion*, incomparably the finest of his minor poems. As in the case of the *Complaints*, the publisher for obvious reasons issued this volume nominally without his authority. *Colin Clout's Come Home Again* was published in the same year, with a dedication to Sir Walter Raleigh, dated 1591. Early in 1596 the second three books of the *Faery Queen* were entered in the register of Stationers' Hall, and in the course of the same year were published his *Four Hymns*, his *Prothalamion*, and his *Astrophel*, a pastoral lament for Sir Philip Sidney, which he dedicated to the countess of Essex.

That Spenser wrote more of the *Faery Queen* during the last two years of his life, and that the MS. perished in the sack of Kilcolman Castle by the rebels, may plausibly be conjectured, but cannot be ascertained. During those years he would seem to have been largely occupied with political and personal cares. He describes himself in the *Prothalamion* as a disappointed suitor at court. He drew up his *View of Ireland* in 1596 when he was in London, and from various circumstances it is evident that he had hopes of some kind from the favour of Essex. The *View*, with its urgent entreaty that Essex should be sent to Ireland, was entered at Stationers' Hall in April 1598, but he did not obtain leave to publish it. Burghley, who had long stood in his way, died in August of that year, and next month Spenser, who seems to have returned to Ireland in 1597, was appointed sheriff of Cork. In October Tyrone's rebellion broke out, and Spenser's house was sacked and burned. The poet himself escaped, and in December was sent to London with despatches. Again he ventured to urge upon the queen his plan for the thorough "reformation" of Ireland. But his own end was near. On the 16th of January 1599 he died at Westminster, ruined in fortune, if not heart-broken, and was buried in Westminster Abbey, near his master Chaucer. Ben Jonson asserted that he perished for lack of bread, and that when the earl of Essex, hearing of his distress, sent him "20 pieces," the poet declined, saying that he had no time to spend them.[1] This report of his end is mentioned also by the author of *The Return from Parnassus*, but, having regard to Spenser's position in the world, it is inherently improbable. Still there is an ugly possibility of its truth. The poet left three sons and a daughter. A pedigree of the family appeared in the *Gentleman's Magazine* for August 1842.

Editions by Todd (8 vols., 1805) and by A. B. Grosart (9 vols., 1882–1884); the Aldine edition, with Life by Collier, and the Globe edition, with Life by J. W. Hales; Dean Church's *Spenser*, in "English Men of Letters" series; Craik's *Spenser and his Poetry* (1845); Mrs C. M. Kirkland's *Spenser and the Faery Queen* (New York, 1847); J. S. Hart's *Essay on the Life and Writings of Edmund Spenser* (New York, 1847); Kitchin and Mayhew's *Spenser's Faery Queen*, bks. i.–ii., and Herford's *Spenser's Shepherd's Calendar* (Oxford, Clarendon Press); Roden Noel's preface to the Spenser volume in the Canterbury Poets; and F. I. Carpenter's *Guide to the Study of Spenser* (Chicago, 1894). (W. M.; F. J. S.)

SPENSER, JOHN (1559–1614), president of Corpus Christi College, Oxford, was educated at Merchant Taylors' school, London, and Oxford. After graduating he became Greek reader in Corpus Christi College, and held that office for ten years, resigning in 1588. He then left Oxford and held successively the livings of Alveley, Essex (1589–1592), Ardleigh, Essex (1592–1594), Faversham, Kent (1594–1599), and St Sepulchre's London (1599–1614). He was also presented to the living of Broxbourne, Hertfordshire, in 1592. In 1607 he was appointed president of Corpus Christi College. After the death of his friend Richard Hooker he edited the first five books of Hooker's *Ecclesiastical Politie* (London, 1604). The introduction to that work and *A Sermon at Paule's Crosse on Esay V., 2, 3* (London, 1615) are his only published writings. He was, however, one of the translators of the authorized version of the Bible, serving on the New Testament committee.

SPENSERIAN STANZA, a form of verse which derives its name from the fact that it was invented by the poet Edmund Spenser, and first used in his *Faery Queene* in 1590. The origin of this stanza has been matter for disagreement among critics of prosody. Schipper has argued that it was adapted from the old French ballade-stanza (see BALLADE). But it is much more probable that it was of Italian origin, and that Spenser, who was familiar with *ottava rima* as it had long been employed in Italy, and was at that very time being used by the school of Tasso, added a line between the Italian fourth and fifth, modified slightly the arrangements of rhyme, and added a foot to the last line, which became an Alexandrine. The form of the pure Spenserian stanza can best be observed by the study of a specimen from the *Faery Queene*:—

Into the inmost temple thus I came,
  Which fuming all with frankincense I found,
And odours rising from the altar's flame.
  Upon a hundred marble pillars round
  The roof up high was rearëd from the ground,
All decked with crowns and chains and garlands gay,
  And thousand precious gifts worth many a pound,
The which sad lovers for their vows did pay,
  And all the ground was strow'd with flowers as fresh as May."

It is necessary to preserve in all respects the characteristics of this example, and the number, regular sequences and identity of rhymes must be followed. It is a curious fact that, in spite of the very great beauty of this stanza and the popularity of Spenser, it was hardly used during the course of the 17th century, although Giles and Phineas Fletcher made for themselves adaptations of it, the former by omitting the eighth line, the latter by omitting the sixth and eighth. In the middle of the 18th century the study of Spenser led poets to revive the stanza which bears his name. The initiators of this reform were Akenside, in *The Virtuoso* (1737); Shenstone, in *The Schoolmistress* (1742); and Thomson, in *The Castle of Indolence* (1748). Mrs Tighe (1772–1810) used it for her once-famous epic of *Psyche*. It was a favourite form at the time of the romantic revival, when it was employed by Campbell, for his *Gertrude of Wyoming* (1809); by Keats, in *The Eve of St Agnes* (1820); by Shelley, in *The Revolt of Islam* (*Laon and Cythna*) (1818); by Mrs Hemans; by Reginald Heber; but pre-eminently by Byron, in *Childe Harold* (1812–1817). Thomas Cooper, the Chartist, wrote his *Purgatory of Suicides* (1845) in Spenserian stanza, and Tennyson part of his *Lotus Eaters*. By later poets it has been neglected, but Worsley and Conington's translation of the *Iliad* (1865–1868) should be mentioned. The Spenserian stanza is an exclusively English form.

SPERANSKI, COUNT MIKHAIL MIKHAILOVICH (1772–1839), Russian statesman, the son of a village priest, spent his early days at the ecclesiastical seminary in St Petersburg, where he rose to be professor of mathematics and physics. His brilliant intellectual qualities attracted the attention of the government, and he became secretary to Prince Kurakin. He soon became known as the most competent of the imperial officials. The most important phase of his career opened in 1806, when the emperor Alexander I. took him with him to the conference of Erfurt and put him into direct communication with Napoleon, who described him as "the only clear head in Russia" and at the instance of Alexander had many conversations with him on the question of Russian administrative reform. The result of these interviews was a series of projects of reform, including a constitutional system based on a series of *dumas*, the cantonal assembly (*volost*) electing the *duma* of the district, the *dumas* of the districts electing that of the province or government, and these electing the Duma of the empire. As mediating power between the autocrat and the Duma there was to be a nominated council of state. This plan, worked out by Speranski in 1809, was for the most part stillborn, only the council of the empire coming into existence in January 1810; but it none the less, to quote M. Chesle,[1] dominated the constitutional history of Russia in the 19th century and the early years of the 20th. The Duma of the empire created in 1905 bears the name suggested by Speranski, and the institution of local self-government (the *zemstvos*) in 1864 was one of the reforms proposed by him. Speranski's labours also bore fruit in the constitutions granted by Alexander to Finland and Poland.

From 1809 to 1812 Speranski was all-powerful in Russia, so far as any minister of a sovereign so suspicious and so unstable as Alexander could be so described. He replaced the earlier favourites, members of the "unofficial committee," in the tsar's confidence, becoming practically sole minister, all questions being laid by him alone before the emperor and usually settled at once by the two between them. Even the once all-powerful war-minister Arakcheyev was thrust into the background. Speranski used his immense influence for no personal ends. He was an idealist; but in this very fact lay the seeds of his failure. Alexander was also an idealist, but his ideals were apt to centre in himself; his dislike and distrust of talents that overshadowed his own were disarmed for a while by the singular charm of Speranski's personality, but sooner or later he was bound to discover that he himself was regarded as but the most potent instrument for the attainment of that ideal end, a regenerated Russia, which was his minister's sole preoccupation. In 1810 and the first half of 1811 Speranski was still in high favour, and was the confidant of the emperor in that secret diplomacy which preceded the breach of Russia with Napoleon.[2] He had, however, committed one serious mistake. An ardent freemason himself, he conceived in 1809 the idea of reorganizing the order in Russia, with the special object of using it to educate and elevate the Orthodox clergy. The emperor agreed to the first steps being taken, namely the suppression of the existing lodges; but he was naturally suspicious of secret societies, even when ostensibly admitted to their secrets, and Speranski's abortive plan only resulted in adding the clergy to the number of his enemies.

[2] Schiemann, *Gesch. Russlands*, i. 77.

On the eve of the struggle with Napoleon, Alexander, conscious of his unpopularity, conceived the idea of making Speranski his scape-goat, and so conciliating that Old Russian sentiment which would be the strongest support of the autocratic tsar against revolutionary France. Speranski's own indiscretions gave the final impulse. He was surrounded with spies who reported, none too accurately, the minister's somewhat sharp criticisms of the emperor's acts; he had even had the supreme presumption to advise Alexander not to take the chief command in the coming campaign. A number of persons in the *entourage* of the emperor, including the grand-duchess Catherine, Karamzin, Rostopchin and the Swedish general Baron Armfield, intrigued to involve him in a charge of treason.[1] Alexander did not credit the charge, but he made Speranski responsible for the unpopularity incurred by himself in consequence of the hated reforms and the still more hated French policy, and on the 17th-29th of March 1812 dismissed him from office. Reinstated in the public service in 1816, he was appointed governor-general of Siberia, for which he drew up a new scheme of government, and in 1821 entered the council of state. Under Nicholas I., he was engaged in the codification of the Russian law (published in 1830 in 45 vols.), on which he also wrote some important commentaries.

See the biography (in Russian) by M. Korff (St Petersburg, 1861). On his public life and constitutional reforms see Theodor Schiemann, *Geschichte Russlands unter Kaiser Nikolaus I.*, Bd. i. *Kaiser Alexander I.* p. 75 seq. (Berlin, 1904); Pierre Chasles, *Le Parlement russe* p. 19 seq. (Paris, 1910), and the works of V. Vagin (St Petersburg, 1872 and Moscow, 1905). Count Nesselrode's letters to Speranski and many references are published in vol. iii. of the *Lettres et papiers du comte de Nesselrode.*

SPERMACETI (from Lat. *sperma*, seed, and *cetus*, a whale), a wax found in the head cavities and blubber of the sperm-whale (*Physeter macrocephalus*), where it is dissolved in the sperm oil while the creature is living; it also occurs in other Cetacea (see Whale Oils). At a temperature of about 6° C. the solid matter separates in a crystalline condition, and when purified by pressure and treatment with weak solution of caustic alkali it forms brilliant white crystalline scales or plates, hard, but unctuous to the touch, and destitute of taste or smell. It is quite insoluble in water, very slightly affected by boiling alcohol, but easily dissolved in ether, chloroform, and carbon bisulphide. Spermaceti consists principally of cetin or cetyl palmitate, $C_{15}H_{31}CO_2C_{16}H_{33}$. The substance is used in making candles of standard photometric value, in the dressing of fabrics, and in medicine and surgery, especially in cerates, bougies, ointments, and in cosmetic preparations.

SPERM-WHALE, or Cachalot (*Physeter macrocephalus*), the largest representative of the toothed whales, its length and bulk being about equal to, or somewhat exceeding those of the Arctic right-whale, from which, however, it is very different

The Sperm-Whale (*Physeter macrocephalus*).

in appearance and structure. The head is about one-third of the length of the body, very massive, high and truncated in front; and owing its size and form mainly to the accumulation of a peculiarly modified form of fatty tissue in the large hollow on the upper surface of the skull. The oil contained in cells in this cavity, when refined, yields spermaceti, and the thick covering of blubber, which everywhere envelopes the body, produces the valuable sperm-oil of commerce. The single blowhole is a longitudinal slit, placed at the upper and anterior extremity of the head to the left side of the middle line. The opening of the mouth is on the under side of the head, considerably behind the end of the snout. The lower jaw is extremely narrow, and has on each side from twenty to twenty-five stout conical teeth, which furnish ivory of good quality, though not in sufficient bulk for most of the purposes for which that article is required. The upper teeth are rudimentary and buried in the gum. The flipper is short, broad, and truncated, and the dorsal fin a mere low protuberance. The general colour of the surface is black above and grey below, the colours gradually shading into each other. The sperm-whale is one of the most widely distributed of animals, being met with, usually in herds or "schools," in almost all tropical and subtropical seas, and occasionally visiting the northern seas, a number having been killed around the Shetlands a few years ago. The food of sperm-whales consists mainly of squid and cuttlefish, but also comprises fish of considerable size. The substance called "ambergris," formerly used in medicine and now in perfumery, is a concretion formed in the intestine of this whale, and found floating on the surface of the sea. Its genuineness is proved by the presence of the horny beaks of the cuttles on which the whale feeds. The one representative of the genus *Cogia* is called the lesser or pigmy sperm-whale, being only from 9 ft. to 13 ft. long.

SPES, in Roman mythology, the personification of Hope. Originally a nature goddess (like Venus the garden goddess, with whom she was sometimes identified), she represented at first the hope of fruitful gardens and fields, then of abundant offspring, and lastly of prosperity to come and good fortune in general, being hence invoked on birthdays and at weddings. Of her numerous temples at Rome, the most ancient was appropriately in the forum olitorium (vegetable market), built during the first Punic war, and since that time twice burnt down and restored. The day of its dedication (August 1) corresponded with the birthday of Claudius, which explains the frequent occurrence of Spes on the coins of that emperor. Spes is represented as a beautiful maiden in a long light robe, lifting up her skirt with her left hand, and carrying in her right a bud already closed or about to open. Sometimes she wears a garland of flowers on her head, ears of corn and poppy-heads in her hand, symbolical of a prosperous harvest. Like Fortune, with whom she is often coupled in inscriptions on Roman tombstones, she was also represented with the *cornu copiae* (horn of plenty).

See G. Wissowa, *Religion und Kultus der Römer* (1902), according to whom Spes was originally not a garden goddess, but simply the divinity to whom one prayed for the fulfilment of one's desires.

SPESSART, a highland forest country of Germany, belonging mainly to the Bavarian province of Lower Franconia, but in the north to the Prussian province of Hesse Cassel, and it is bounded on the S. and W. by the Main, on the E. by the Sinn and on the N. by the Kinzig and Joss. The main ridge of the formation, consisting of gneiss, granite and red sandstone, runs from a point opposite Miltenberg, in a north-westerly direction to the source of the Kinzig near Schlüchtern—a distance of 45 m.—and attains its highest elevation in the Geiersberg (1919 ft.), which lies north of the Rohrbrunn pass, through which runs the main road from Aschaffenburg to Würzburg. The forest, with which it is densely covered, consists of oak, beech, ash and fir, and the scenery, especially on the main side, between Gemünden and Lohr, is impressive. The climate is inclement in winter and oppressively hot in midsummer. The inhabitants are engaged chiefly in woodcutting, raft-making and quarrying, and most of the timber is floated down to Holland. Cobalt, silver, lead and copper are also worked, and the southern and western slopes yield wine of good quality. This beautiful tract of country until recent years was comparatively little known to the tourist, but a club (*Spessart Klub*) through the establishment of finger-posts and the issue of maps, has indicated the more interesting tours to be followed.

See Bücking, *Der nordwestliche Spessart, geologisch aufgenommen* (Berlin, 1893); Schober, *Führer durch den Spessart* (Aschaffenburg, 1904); Wolff, *Der Spessart, sein Wirtschaftsleben* (ibid., 1905).

SPEUSIPPUS (4th century B.C.), Greek philosopher, son of Eurymedon and Potone, sister of Plato, is supposed to have been born about 407 B.C. He was bred in the school of Isocrates;

but, when Plato returned to Athens about 387, yielded to his influence and became a member of the Academy. In 361, when Plato undertook his third and last journey to Sicily, Speusippus accompanied him. In 347 the dying philosopher nominated his nephew to succeed him as scholarch, and the choice was ratified by the school. Speusippus held the office for eight years, and died in 339 after a paralytic seizure. According to some authorities he committed suicide. There is a story that his youth was riotous, until Plato's example led him to reform his ways. In later life he was conspicuously temperate and amiable. He was succeeded by Xenocrates.

Of Speusippus's many philosophical writings nothing survives except a fragment of a treatise *On Pythagorean Numbers*. Nor have secondary authorities preserved to us any general statement or conspectus of his system. Incidentally, however, we learn the following details. (A) In regard to his theory of being: (1) whereas Plato postulated as the basis of his system a cause which should be at once Unity, Good, and Mind, Speusippus distinguished Unity, the origin of things, from Good, their end, and both Unity and Good from controlling Mind or Reason; (2) whereas Plato recognized three kinds of numbers—firstly, ideal numbers, *i.e.* the "determinants" or ideas; secondly, mathematical numbers, the abstractions of mathematics; and thirdly sensible numbers, numbers embodied in things—Speusippus rejected the ideal numbers, and consequently the ideas; (3) Speusippus traced number, magnitude and soul each to a distinct principle of its own. (B) In regard to his theory of knowledge: (4) he held that a thing cannot be known apart from the knowledge of all things besides; for, that we may know what a thing is, we must know how it differs from other things, which other things must therefore be known; (5) accordingly, in the ten books of a work called Ὅμοια, he attempted a classification of plants and animals; (6) the results thus obtained he distinguished at once from "knowledge" (ἐπιστήμη) and from "sensation" (αἴσθησις), holding that "scientific observation" (ἐπιστημονικὴ αἴσθησις), though it cannot attain to truth, may, nevertheless, in virtue of a certain acquired tact, frame "definitions" (λόγοι). (C) In regard to his theory of ethics: (7) he denied that pleasure was a good, but seemingly was not prepared to account it an evil.

In default of direct evidence, it remains for us to compare these scattered notices of Speusippus's teaching with what we know of its original, the teaching of Plato, in the hope of obtaining at least a general notion, firstly, of Speusippus's system, and, secondly, of its relations to the systems of Plato, of contemporary Platonists, such as Aristotle, and of the later Academy.

It has been suggested elsewhere (see SOCRATES) that the crude and unqualified "realism" of Plato's early manhood gave place in his later years to a theory of natural kinds founded upon a "thoroughgoing idealism," and that in this way he was led to recognize and to value the classificatory sciences of zoology and botany. More exactly, it may be said that the Platonism of Plato's maturity included the following principal doctrines: (i.) the supreme cause of all existence is the One, the Good, Mind, which evolves itself as the universe under certain eternal immutable forms called "ideas"; (ii.) the ideas are apprehended by finite minds as particulars in space and time, and are then called "things"; (iii.) consequently the particulars which have in a given idea at once their origin, their being, and their perfection may be regarded, for the purposes of scientific study, as members of a natural kind; (iv.) the finite mind, though it cannot directly apprehend the idea, may, by the study of the particulars in which the idea is revealed, attain to an approximate notion of it.

Now when Speusippus (1) discriminated the One, the Good, and Mind, (2) denied the ideas, and (3) abandoned the attempt to unify the plurality of things, he explicitly rejected the theory of being expressed in (i.) and (ii.); and the rejection of the theory of being, *i.e.* of the conception of the One evolving itself as a plurality of ideas, entailed consequential modifications in the theory of knowledge conveyed in (iii.) and (iv.). For, if the members of a natural kind had no common idea to unite them, scientific research, having nothing objective in view, could at best afford a λόγος or definition of the appropriate particulars; and, as the discrimination of the One and the Good implied the progression of particulars towards perfection, such a λόγος or definition could have only a temporary value. Hence, though, like Plato, Speusippus (4) studied the differences of natural products (5) with a view to classification, he did not agree with Plato in his conception of the significance of the results thus obtained; that is to say, while to Plato the definition derived from the study of the particulars included in a natural kind was an approximate definition of the idea in which the natural kind originated, to Speusippus the definition was a definition of the particulars studied, and, strictly speaking, of nothing else. Thus while Plato hoped to ascend through classificatory science to the knowledge of eternal and immutable laws of thought and being, Speusippus, abandoning ontological speculation, was content to regard classificatory science not as a means but as an end, and (6) to rest in the results of scientific observation. In a word, Speusippus turned from philosophy to science.

It may seem strange that, differing thus widely from his master, Speusippus should have regarded himself and should have been regarded by others as a Platonist, and still more strange that Plato should have chosen him to be his successor. It is to be observed, however, firstly, that the scientific element occupied a larger place in Plato's later system than is generally supposed,[1] and, secondly, that other Academics who came into competition with Speusippus agreed with him in his rejection of the theory of ideas. Hence Plato, finding in the school no capable representative of his ontological theory, might well choose to succeed him a favourite pupil whose scientific enthusiasm and attainment were beyond question; and Speusippus's rivals, having themselves abandoned the theory of ideas, would not be in a position to tax him with his philosophical apostasy.
